Dear Sir,

George is rather heavy to day from being broke of his
rest last night—the Symptoms of the disorder how
ever are entirely off, & I expect after a nights sleep
to find him well—

Ichabod has passed thro the easiest of either—

Benj s Symptoms come on last & he still feels more
of them than the others—I expect he will have the
largest crop of pustles, I am not however apprehensive
at present of so many as to be troublesome—

Charlotte feels a litle of y^c Symptoms yet & will prob-
ably next to Benj have the most pock—

Yours with Respect

M L

NOTES

1 Robert Ellis, surgeon, was the son of a surgeon, Edward Ellis, and the father of two surgeons, Edward and Thomas Ellis. In 1677 Edward Ellis, his father, is styled "chirurgeon" and in 1695 Robert Ellis is styled "barber chirurgeon, but later he too is called "chirurgeon. He lived in Boston at the corner of Winter and Newbury (now Washington) streets. The date of his death may be approximated through the fact that his will was dated February 23, 1719 and proved April 18, 1720¹

2 Zabdiel Boylston (1679-1766), of Brookline, is too famous for having introduced inoculation against smallpox into America to receive more than passing mention here. In the spring of 1721 Boston was invaded by smallpox from Barbados, the Rev Cotton Mather suggested to Dr Boylston that the Eastern practice of inoculation be tried, and two days later (June 26, 1721) Dr Boylston inoculated his first patient. Against the opposition of other physicians and of a thoroughly aroused mob, and at the risk of his life, he persevered, and probably inoculated about two hundred and forty persons in all, the mortality was reduced from 12 to 15 per cent to a little over 2 per cent²

3 Francis Gahman was born in Hamburg, Germany, during the 1670s, and was living as late as 1740³. He appears in Salem as early as August 24, 1702, on which date, "being presently bound out to sea in a voiage in the good sloop called *The Charles* whercof Capt. Peter Lawrence is present commander against y^c French and Spaniards", he assigned to Henry Sharp of Salem, painter, because of a debt of £44.7s.9d, his share of any prizes that may be taken by Capt. Lawrence, together with his clothes, medicines and surgical instruments⁴. In the summer of 1703 John Quelch, mate of the brigantine *Charles* threw the captain, who was ill, overboard, and assumed command as a pirate, returning to Marblehead in May, 1704. It was rumored that he had been joined by Capt. Larimore, of Cape Ann, who had previously been a respectable privateersman. When a group of pirates had been located on Cape Ann, an armed force was sent to catch them, and the judges rode to Salem and got more information from Doctor Gatchuman [probably Gahman], whom they sent to the Governor to make a report. The pirates were captured at the Isles of Shoals and duly hanged in Boston.⁵ Dr Gahman's part did not end here, for we find "1729 April 17 A petition of Francis Gahman, of Salem, Chyrurgeon, showing, that by order of this Government, 1704, Capt. Laramore and others were sent to England to receive their tryals, as accessories to Quelch's piracy, he was sent over with them, and in his passage was taken and carried captive into France and lost his cloathing, books, chyrurgeon s chest and instruments, to a considerable value, praying for such relief as the Court shall think proper Referred to the next May session."⁶ The year 1708 finds him back in Salem, for in that year he married Mrs. Lydia West,⁷ and later records about him are all of a peaceable and unexciting character—we find him signing a paper drawn up at a meeting of the proprietors of the common lands in 1713-1714,⁸ being paid for his share in building a stone wall along the Lynn line in 1723,⁹ bleeding a patient who kept a diary—James Jeffry—in 1724,⁹ and mentioned as a communicant of the First Church in Salem in 1734-1735¹⁰. His name has been regularly mis-spelled, but his two signatures on this receipted bill show its correct spelling. As to the items ceracloth" is apparently cerecloth or waxed cloth "Empr Matricie" is undoubtedly the emplastrum hystericum or Mutter Pflaster of the Ger-

Dr Sharples was guest speaker at a recent meeting of the Whitefield Woman's Club. In a discussion of 'Preventive Medicine' he gave a brief outline of the incidence of common diseases, and the work being done toward their prevention by private physicians and the federal, state and local health organizations.

MISCELLANY

MASSACHUSETTS TUBERCULOSIS LEAGUE

At the annual meeting of the Massachusetts Tuberculosis League, Incorporated, the following officers were elected for the ensuing year: Dr Frederick T. Lord, Boston, president; Clifton H. Hobson, Palmer, and Dr Francis P. Denny, Brookline, vice presidents; Arthur Drinkwater, Cambridge, treasurer; Rodney Spring, Boston, assistant treasurer; Arthur J. Strawson, Newtonville, clerk; Dr Henry D. Chadwick, the Rt. Rev. William Lawrence, Rabbi Harry Levi and Cardinal O'Connell were chosen honorary vice presidents.

The meeting was followed by a talk by Dr Lord on the prevention and control of tuberculosis in Massachusetts, and one by Dr Robert E. Plunkett concerning the preventive research work in tuberculosis being carried out by the New York State Department of Health.

NOTES

At the fifth annual meeting of the American Institute of Nutrition, Dr T. M. Carpenter, of the Carnegie Institution, Boston, was elected vice president and Dr Helen S. Mitchell, of Massachusetts State College, was made a member of the council.

Dr G. Philip Grabfield, associate in pharmacology, Harvard Medical School, was elected secretary of the American Society of Pharmacology and Experimental Therapeutics at a recent meeting in Baltimore.

During the week beginning April 18 at the Peter Bent Brigham Hospital in Boston, Dr Emil Goetsch, first resident surgeon, now professor of surgery at the Long Island Medical College, and Dr Francis G. Blake, first of now living resident physicians, at present Sterling Professor of Medicine, at Yale University School of Medicine, served respectively as surgeon-in-chief, pro tempore, and physician-in-chief, pro tempore.

CORRESPONDENCE

PERIODIC MEDICAL EXAMINATION OF ADULTS IN CONTACT WITH CHILDREN

To the Editor—Our attention has been called to an editorial under the title 'An Opportunity for the District Medical Society' in your issue of March 24, in which you have commented favorably upon a plan for periodic medical examination of adults in contact with children that is being promoted by this Society.

Your comments in my opinion very faithfully interpret the underlying purpose of this work and we should be glad to assure the district medical societies through your good offices that it would be a pleasure for us to be of service to any of those societies which may desire to have more explicit information on the subject of this program.

JAMES BRYAN, *Executive Secretary*,

1739

that the skin lesions were due to syphilis or tuberculosis. He administered intramuscular bismuth with marked improvement of the skin lesions, and advised a lumbar puncture which was refused by the patient.

Two weeks before her entry to the hospital the patient consulted another physician who found a doubtful Hinton test and gave her an injection of arsphenamine in an attempt to produce a 'provocative reaction.' A second injection of arsphenamine was given one week later, and was followed by a shaking chill, three days of asthenia, and the sudden onset of weakness and collapse on the fourth day with complete loss of motor and sensory function in both legs and incontinence of urine and feces. She was immediately admitted to the hospital.

At the time of entry she was incontinent, her bladder was distended, the abdominal reflexes were absent, the knee jerks were markedly diminished, the Babinski reaction was present bilaterally, and there was ankle clonus. Sensation was absent below the buttocks posteriorly, and the groins anteriorly. Ten days after entry the reflexes of the legs were hyperactive, and the Babinski were still positive bilaterally. Two lumbar punctures yielded bloody fluid, thought to be due to trauma, the Wassermann reactions on both samples were negative. Four specimens of blood were taken. The Hinton test was doubtful in all four, while the Wassermann was positive in the first three and negative in the last. Tidal drainage of the bladder was instituted, and general supportive measures followed. There had been marked improvement, with return of most sensory and a great deal of the motor function. The knee jerks were still hyperactive, and the Babinski were still positive.

Dr C. Sidney Burwell stated that although the time relation between the injections of the arsphenamine and the transverse myelitis was impressive the mechanism of the production of the lesion was not understood. The arsenic may have produced its effect by direct action on the spinal cord, or by causing in an area of syphilitic inflammation an acute edema with partial or complete arteriolar occlusion and secondary spinal-cord change. Arsenic may also cause acute damage to the arteriolar wall itself, and hemorrhagic lesions are occasionally produced. In addition to transverse myelitis, acute hemorrhagic encephalitis may follow the administration of arsenicals. The prognosis in the present case was believed to be favorable.

The remainder of the evening's program was presented by Drs. Richard P. Strong, Henry Pinkerton and David Weinman who spoke on "Medical Investigations in Peru in 1937." Dr Strong briefly outlined the historical development of our knowledge of the etiology of yellow fever, and the mechanism of its transmission.

Sanarelli in 1897 reported that an organism, *Bacillus icteroides* caused the disease, and although this claim was confirmed by several investigators in the United States, it was later disproved. In 1900, Reed, Carroll, Lazear and Agramonte established the fact that the infective agent was present in the blood and that yellow fever is transmitted by the mosquito, *Aedes aegypti*. Although subsequent work (1905) showed that the virus was filterable, in 1909 Seidelin reported in the red cells an organism which he named *Paraplasma flavigenum*. Tyzzer, Sellards, and Dr Strong were unable to find these structures in the red cells when they studied yellow fever in Guayaquil in 1913. Also, they were unable to cultivate any organism from the blood though they used Noguchis spirochetal media of that time. Noguchi, however, also working in Guayaquil, believed that he had found the causative organism in 1918 when he demon-

strated and cultivated *Leptospira icteroides* from guinea pigs inoculated with the blood of jaundiced patients. Later investigations showed that this organism was identical with that causing epidemic jaundice (Weil's disease), and that perhaps the patients used by Noguchi were suffering from the latter disease and not yellow fever, or that the guinea pigs were infected with hemorrhagic jaundice. The present belief is that yellow fever is caused by a filterable virus.

Until 1932 yellow fever was believed to be especially a coastal disease and to affect particularly the population of our large seaports. Its favorable haunts were squalid low lying areas with open drainage systems and heavy mosquito infestation. It was thought to be essentially a mosquito-borne disease. Rarely was it known to extend far inland or to ascend high altitudes.

However, in 1932 Soper and his associates of the Rockefeller Foundation called attention to the discovery of yellow fever in Brazil and elsewhere in South America, in rural areas or sparsely populated jungle districts, and, importantly, in the absence of *A. aegypti*. A number of outbreaks have been reported in the past few years, and a few at altitudes of 2000 feet or over.

While in South America in 1937, Hanson and Dr Strong were asked to investigate an epidemic that was occurring on a coffee plantation on the eastern slopes of the Andes, at an elevation of 2500 feet. The nature of the epidemic was unknown. A study of the epidemic was made and an autopsy on a fatal case revealed the typical saffron-ocher liver with slight nutmeg mottling, the hemorrhagic gastritis with clots of dark blood in the stomach and duodenum, and the acute parenchymatous nephritis, which, together with the subsequent study of sections of the organs, established the diagnosis of yellow fever. Diligent search failed to reveal the presence of *A. aegypti* or other possible insect vectors for the disease. No explanation of the mode of transmission of the disease in inland regions has yet been found, though it is a problem which the Rockefeller Foundation is still studying.

The expedition to Peru in 1937, as was the expedition of 1913, was organized for the purpose of studying Oroya fever or verruga peruviana. This disease was referred to over four centuries ago when the Portuguese and Spanish invaders of Central and South America were said to be afflicted with it, and to suffer a high mortality. De la Vega stated that one quarter of Pizarro's forces succumbed to its ravages. The disease is characterized by fever, anemia and an eruption upon the skin. Often two stages are observed: in the first, Oroya fever, there is fever and marked anemia, in the second, verrugous lesions appear, sometimes only the second stage is apparent. If the patient survives the first stage of the disease, later a miliary eruption may occur, and subcutaneous, cherry-red, easily bleeding nodules develop, which may later become 7 or 8 cm. in diameter and tend to become eroded.

Barton in 1909 described bodies in the red blood corpuscles which he thought were probably the cause of the disease. In 1913, Tyzzer, Sellards and Dr Strong observed these bodies, and after studying them, believed they were parasitic, in honor of Barton, they named the organism *Bartonella bacilliformis*. The organism is rod shaped or rounded. The rods measure 1.5 to 2.5 μ in length, and the rounded form 0.5 to 1 μ in diameter. The anemia is frequently very severe and fatal. The red blood cells may be less than 1,000,000 per cubic millimeter. In severe cases over 90 per cent of the red cells are invaded by the parasite. The anemia is macrocytic in type, with marked anisocytosis and poikilocytosis, and the appearance of normoblasts and megaloblasts.

mans, the curious may learn its composition in Dr Woyt's *Gazophylacium Medico-Physicum* (1751)

4, 5, 6 Dr John Cabot was the son of John Cabot of Salem, merchant. He was born in Salem in 1704, took the degree of A.B. at Harvard in 1724 and that of A.M. there in 1727, was placed twenty-first in his college class of forty, and was engaged in the practice of medicine in Salem by 1729. He died in Salem in 1749 leaving a widow and two young children, the latter died in 1750 and 1759, so that he left no descendants.^{8, 11, 12}

7 Ebenezer Putnam, originally of Danvers, received the degree of A.B. at Harvard College in 1739 and that of A.M. in due course, he was placed seventeenth in a class of thirty-two. By the year 1744 he was practising medicine in Salem, where he joined the First Church and was chosen presiding elder on the death of Judge Ropes. He and Dr Edward Augustus Holyoke, both "loyalists of the passive sort," were men of high standing in the community. In 1760 both are found among the founders of the Social Library. He died in 1788.^{8, 11, 12} His patient, Capt. Joseph Bowditch, was paralysed for the last nine years of his life, as he died in 1780 it seems likely that the date of Dr Putnam's first visit, 9 July 1771, was that of the stroke.

8 Colonel David Mason, the owner of the electrical machine, was an important figure in Salem, and took a prominent part in the episode at the North Bridge in 1775, when Colonel Leslie was obliged to retreat to Marblehead without capturing the guns which Colonel Mason had been instrumental in obtaining for the patriot party. He was a student of electricity and a friend of Benjamin Franklin, although some twenty years his junior.¹³ This is no doubt an early instance of the use of electricity for paralysis.

9 Moses Little took the degree of A.B. at Harvard in 1787 and that of A.M. in 1804, he died in 1811.¹² There is nothing to show that this Moses Little was a physician, but a letter from a correspondent in Salem, writing June 2, 1811, says "Doctor Little is confined to his chamber & says that for sometime past he has expected to die, but did not think he should have fallen away so fast." The correspondence of dates makes it practically certain that we are dealing with the same man. He might have attended the medical school in Boston, for the first class was graduated from there in 1788, but the apprentice system, which Dr Little no doubt followed, was long in coming to an end. The internal evidence shows that this letter was written to Capt. Ichabod Nichols, of Salem, concerning four of his children who were no doubt under Dr Little's care for inoculation against smallpox. The ages of the children may be of interest. George was sixteen, Ichabod ten, Benjamin eight and Charlotte six. All recovered, and died at the following ages. George at eighty-seven, Ichabod at seventy-five, Benjamin at sixty-two and Charlotte at eighty-four.

REPORT OF MEETING

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital Tuesday evening, January 25, Dr S. Burt Wolbach presiding.

The surgical case was presented by Dr James B. Blodgett. The patient, a fifty-five-year-old Russian salesman, was first seen in the outpatient department two and a half months previously, at which time he complained of an inguinal hernia and of a chronic cough, both having been present for fifteen years. An x-ray taken at that time revealed a substernal mass and a triangular shadow in the periphery of the left lung field. The latter shadow was interpreted as a classical infarct of the lung. An x-ray taken one month later showed the triangular shadow to be larger, and he was hospitalized. At that time it was learned that he had suffered from weakness for the eight months preceding entry, and had lost 10 lb in weight. Physical examination revealed a substernal mass which moved with deglutition, a few rales in the left chest, and a right direct inguinal hernia. Roentgenograms showed an increase in the size of the shadow in the left chest, the edges of which were rounded, suggesting a neoplastic process. The basal metabolic rate was +66, the cholesterol 235 mg per cent, and the white-cell count 14,000. In spite of the markedly elevated basal metabolic rate there was no clinical evidence of thyrotoxicosis. The thyroid gland was removed for histologic study and relief of pressure symptoms, which the patient had experienced for a short time.

Dr Elliott C. Cutler, in commenting on the case, stated that no definite diagnosis of the mass in the left chest could be made, although metastatic carcinoma of the thyroid was a definite possibility. Dr Wolbach described the histologic picture of the removed thyroid, which appeared to be an embryonal adenoma in some areas, and a fetal adenoma in others. Such glands are not to be considered as true adenomas, but as a condition of compensatory hyperplasia. It is unusual for such a type of gland to give rise to metastases.

The second case was from the medical service. The patient, a twenty-eight-year-old, white housewife, suffered the sudden onset of transverse myelitis one month previously and was immediately admitted to the hospital. The past history was essentially negative. She had been married eight years, and had a seven-year-old child. Serological tests on both the husband and child were negative. Six months before entry to the hospital she consulted her local physician because of a persistent skin rash of one and a half years duration. Her physician found that during a routine examination at the age of fourteen years a positive Wassermann reaction and a negative Hinton test were discovered. No therapy was given at that time. Similar results (positive Wassermann and doubtful Hinton) were reported by the hospital at the time of her delivery seven years previously, but the serological tests were not repeated and no therapy was given at that time. Her local physician found that the Wassermann reaction was negative, and the Hinton test doubtful, and believed

MASSACHUSETTS MEMORIAL HOSPITALS

The annual reunion of the House Officers Alumni Association of the Massachusetts Memorial Hospitals will be held on Saturday, April 23. The morning will be devoted to clinics by the medical, surgical, pediatric, obstetrical and outpatient departments and the staff of the Evans Memorial. These will start at 10:00, and will be followed at 12:30 by a luncheon and a business meeting.

The following papers by members of the staff will be read in the afternoon:

- 2:00-2:20 Two Cases of Leg Lengthening
Dr. Daniel M. Killoran.
- 2:20-2:40 Comparative Results with Different Methods of Handling the Appendiceal Stump
Dr. Welman B. Christie.
- 2:40-3:00 Carcinoma of the Colon.
Dr. Clifford D. Harvey.
- 3:00-3:20 Osteomyelitis of the Frontal Bone.
Dr. Leighton F. Johnson.
- 3:20-3:40 A Fifteen Year Calculus Survey of the Massachusetts Memorial Hospitals.
Dr. Myron J. Hahn.
- 3:40-4:00 Recent Advances in the Treatment of Cancer
Dr. Thomas J. Anglem.
- 4:00-4:20 Radiation of Inflammatory Lesions.
Dr. George Levene.
- 4:20-4:40 Parathyroid Tumors.
Dr. Louis G. Howard.

Cocktails will be served at the Hotel Kenmore from 5:20 to 7:00, to be followed by the annual banquet.

THE MASSACHUSETTS PUBLIC HEALTH ASSOCIATION

The April meeting of the Massachusetts Public Health Association and its sections will be held on Wednesday, April 27, at the University Club, 40 Trinity Place, Boston.

The section meetings will start at 11:00 a. m. Luncheon will be served at 1:00 p. m., after which Dr. Cecil K. Drinker will speak on "The Spread of Infections in the Respiratory Tract."

The programs for the different sections are as follows:

BOARD OF HEALTH SECTION

The Preparation and Scope of a Municipal Sanitary Code. Dr. Murray P. Horwood.

LABORATORY SECTION

- The Laboratory Diagnosis of Virus Diseases. Dr. Sidney C. Dalrymple.
- New Developments in Milk Technology. Dr. Robert E. Bemis, and Mr. A. A. Robertson.
- Movies on Bacteriological Technic. Dr. Alice T. Marston.

CHILD HYGIENE AND PUBLIC HEALTH NURSING SECTION

- Business meeting
- The Outlook for an Appraisal of Nutrition. Dr. Harold Stuart.

ERNEST M. MORRIS, M.D., *President*,
G. DONALD BUCKNER, *Secretary*

AMERICAN HEART ASSOCIATION

The fourteenth scientific session of the American Heart Association will be held on June 10 and 11 from 9:30 a. m. to 5:30 p. m. in the Sir Francis Drake Hotel, San Francisco, California.

On Friday, June 10, the general heart program will be given, and on Saturday, June 11, the program of the Section for the Study of the Peripheral Circulation.

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Boston Medical Library on Monday, April 25, at 8:15 p. m.

PROGRAM

- Heart Disease in Pregnancy at the Worcester City Hospital. Dr. F. B. Carr, of Worcester.
- Electrocardiographic Changes in Vitamin B Deficiency. Drs. C. C. Dustin, H. L. C. Weyler and C. P. Roberts, of Providence, Rhode Island.
- Gall-Bladder Disease and Coronary Sclerosis. Dr. E. H. Drake, of Portland, Maine.
- A Case of Hemophilia with Hemopericardium as a Result of Trauma. Dr. C. C. Dustin, of Providence, Rhode Island.
- Clinical Observations on the Use of Quinidine. Dr. James Z. Naurison, of Springfield.
- Auricular Flutter. Report of an unusual case with some remarks about the history of our knowledge of this disorder. Dr. Frank T. Fulton, of Providence, Rhode Island.

Interested physicians and medical students are invited to attend.

JAMES M. FAULKNER, M.D., *Secretary*

COURSE IN OCCUPATIONAL DERMATOSES

During May, 1938, a course in occupational dermatoses will be given under the auspices of the Harvard School of Public Health. Lectures will be given on the clinical manifestations, aspects and so forth. Clinics will be held at the Massachusetts General Hospital, and at the offices of various insurance companies. Visits to some of the more important factories will be arranged, so that students may study industrial processes and preventive measures. The number of students will be limited to ten. Further information and registration blanks may be obtained from the Dean of the Harvard School of Public Health, 25 Shattuck Street, Boston, Mass.

In 1913 attempts to cultivate this organism, especially on Noguchi's spirochetal media of this period, were unsuccessful. However, Dr Strong and his associates were able to inoculate monkeys successfully with material from human verruga nodules, and to reproduce the characteristic nodules through a long series of these animals. A monkey and two rabbits inoculated intravenously with blood from a human case of Oroya fever with anemia, containing large numbers of *B bacilliformis* in the red cells, did not develop any verrugas, nor were other lesions found in them. Also, a man, who volunteered, was inoculated cutaneously with a human verruga nodule, and did not develop fever, anemia or *B bacilliformis* in the blood, but only a local verruga lesion. The results of such experimental work obviously did not demonstrate or permit the assumption upon a scientific basis that the pathologic processes involved in Oroya fever and the verruga stage of the disease were identical.

However, by 1926, Noguchi had greatly improved his leptospiral media which he had also used for the cultivation of protozoa, and in this year he was able to cultivate *B bacilliformis* from blood of Oroya fever cases sent to him in New York. Battistini was associated in this work. On the expedition of 1937, using this same media, Dr Strong and his associates were able to confirm and extend this work.

The disease is found only in regions lying between 2400 and 8000 feet in elevation, where the climatic conditions are peculiar—receiving little rain, and situated along the banks of small rivers. While the method of transmission has not been demonstrated there is some evidence which indicates that *Phlebotomus*, a small blood sucking sand fly, may be concerned in the transmission. Both Townsend and Shannon and several others have been in favor of the view of such transmission, and Shannon has recently made a very valuable epidemiological contribution to the subject. Dr Hertig is at present in Peru carrying on further observations in this connection.

Dr Pinkerton described the pathologic lesions of verruga peruviana, and the cultural characteristics of the Bartonellae. Histologically the verrugous lesions appear to be multiple rapidly growing hemangiomas, somewhat resembling the hemorrhagic sarcoma of Kaposi. Bartonellae can be demonstrated in the endothelial cells during the verrugous stage, and appear to be the cause of the tumors. Cutaneous lesions were produced in monkeys by using Bartonellae isolated from human cases suffering from the febrile stage, and cultured on Noguchi's medium. This suggested that the two stages of the disease, verruga peruviana, had a similar etiology. A comparative study of the viruses isolated from the acute febrile and the verrugous stages gave further support to the theory that both have a common etiology. As cultured in tissue culture both viruses had identical growth patterns within cells. Unlike the Rickettsiae, which grow only intracellularly, the Bartonellae will grow outside the cells of the tissue culture as well as within cells. The morphology of the Bartonellae as demonstrated by special staining methods in the tissue of cases of the febrile and verrugous stages was also found to be identical.

Dr Weinman described the characters of the Bartonellae, and the production of the various forms of Carrion's disease in monkeys. The verrugous and the anemic forms were both produced in *Macacus rhesus* monkeys by injecting organisms obtained directly from human beings with the anemic form of the disease, splenectomy prior to inoculation greatly facilitated the productions of the anemic form. Nine per cent of the persons studied in a Peruvian village where Carrion's

disease is endemic were found to be infected with Bartonellae, although they were without symptoms. Some of these individuals had never suffered from the disease; others gave a history of previous illness. This infected portion of the population may serve as a reservoir for the disease. Experimental asymptomatic infection of the monkey was also obtained. Peruvian guinea pigs from the endemic regions were found to be infected with Bartonellae, although investigation showed that these organisms were different in type from the human form. The natural means of transmission of the disease still remains undetermined.

NOTICES

HENRY JACKSON LECTURE

The Henry Jackson Lecture for 1938 offered by the New England Heart Association will be given by Louis Hamman, M.D., associate professor of clinical medicine, Johns Hopkins University School of Medicine, at 8 15 p.m. on Friday, April 29, at the Boston Medical Library. His subject will be "The Diagnosis of the Causes of Heart Failure."

The annual business meeting of the New England Heart Association will precede the lecture.

RADIO BROADCASTS

The eighth group of weekly broadcasts sponsored by the American Medical Association and the National Broadcasting Company concern hygiene. These dramatized health messages are intended to furnish supplementary material for health teaching in junior and senior high schools and are broadcast every Wednesday from 2:00 to 2:30 p.m. over the Red Network. The dates and subjects are as follows:

April 27—Healthier Babies. Daily routine of the healthy baby, medical supervision, feeding.

May 4—Healthier Mothers. General advice for the expectant mother, good for boys and girls to know about.

May 11—Hospitals Aid Health. The place of the hospital in the health program of the individual and the community.

May 18—Runabouts, 1938 Model. The preschool child and the health and personality problems of that age.

CANCER CLINIC

A cured-case teaching cancer clinic will be held at the Boston Dispensary on Friday, April 29, at 11 30 a.m., at which time a variety of cured cases will be shown and methods of treatment discussed.

Physicians are cordially invited to attend.

CAMBRIDGE HOSPITAL

The regular clinicopathological meeting of the staff of the Cambridge Hospital will be held at the Cambridge Hospital, 330 Mt. Auburn Street, on Tuesday, April 26, at 8 30 p.m.

Dr Stanley Nowak and Dr Stephen Maddock will discuss sudden death in liver disease.

All members of the medical profession are cordially invited to attend.

BOOK REVIEWS

Surgical Pathology of the Diseases of the Neck Arthur E. Hertzler 237 pp Philadelphia, Montreal and London J B Lippincott Company, 1937 \$5.00

This work is the tenth of Hertzler's monographs on surgical pathology. In the preface to this volume the author deplors "the present tendency to treat all lesions of the neck by irradiation without a definite pathologic diagnosis and adds what surgeons have learned is in grave danger of being lost by the practice."

He proceeds in a clear, concise and orderly manner to discuss not only the gross and microscopic pathology of the diseases of the neck but also their life history. The study is, therefore, of great practical value to the clinician and surgeon in the differential diagnosis of these conditions. To this end the many excellent illustrations are of valuable assistance. The pages carry 206 illustrations. Ninety-eight are pictures of patients showing the early and progressive appearances of the various diseases. The remaining cuts (except two roentgenograms of the chest) illustrate gross and microscopic pathology.

The subject is discussed under ten chapter headings: preview of surgical affections, Hodgkin's granuloma, lymphosarcoma, lymphoepithelioma, rare primary tumors, vestigial rests, benign tumors, salivary tumors, secondary tumors and inflammatory affections (Hertzler has dealt with diseases of the thyroid gland in a previous monograph.) Following each chapter is a short bibliography with appraisals by the author. The text is often colored by picturesque expressions.

The physical make up of the volume is attractive. The paper is highly calendered. The typography is excellent. The book merits a place on the shelves of every general surgeon.

Pathology of the Central Nervous System Cyril B Courville. 344 pp Mountain View, California Pacific Press Publishing Association, 1937

This book adequately covers the subject and, moreover, gives many new, fresh points of view in regard to the pathology of the nervous system. The author has been fortunate in having had at hand for statistical data and examination the brains and spinal cords in a series of 15,000 autopsies performed at the Los Angeles County Hospital. His book is the result of his labors in this field.

The usual aspects of the subject are covered: congenital anomalies, malformations, diseases of the blood vessels, infectious diseases, trauma, intoxications and tumors. Two chapters are worthy of special comment, the one on the infectious diseases of the nervous system covers the field

more adequately than any other textbook, and the same may be said about the section on trauma. A series of excellent illustrations of pathologic material, both gross and microscopic, plus many diagrams and drawings, illustrates the volume. Particularly useful are the drawings in the chapter on trauma, showing the mechanism of injuries to the nervous system, and those delineating the sources of metastatic tumors from other organs. As an appendix there is an unusual chapter on clinicopathological aphorisms, and the book closes with an adequate index.

Printed on rather heavy, shiny paper, the book is not particularly attractive typographically. The matter in it, however, is the product of a thoughtful, ingenious, painstaking individual and deserves wide reading. Although there have been a number of books on the pathology of the nervous system published in recent years, this volume, unique in character, deserves a place in every neurologist's library. The subject is, perhaps, a little oversimplified for the neurological expert, but for students it offers a splendid text.

Macleod's Physiology in Modern Medicine Edited by Philip Bard et al. Eighth edition. 1051 pp St. Louis The C. V. Mosby Company, 1938 \$8.50

This book appears in a new eighth edition, revised and largely rewritten by Prof. Philip Bard, of Johns Hopkins, with the help of eight collaborators, leaders in special physiological fields. In this edition, the section on the physicochemical basis of physiologic processes has been omitted, and the book as a whole contains less physiologic chemistry, allowing room for the expansion of other material. A satisfactory arrangement is the division into large and small type, some of the clinical applications, methods and more technical considerations being given in the small print.

From the clinical point of view, one notes that brief mention only is given the new precordial lead in electrocardiography. The old terms for right and left bundle-branch block are used, while the newer and exactly opposite interpretation, now generally accepted by clinicians, is only mentioned as a possibility.

This is not primarily a book on applied physiology, but a broadly based textbook. Its suitability, however, is by no means limited to medical students. Any practitioner, and particularly any clinician who pretends to master the field of his special interest, will find fundamental physiology brought up to date, together with adequate references to a further perusal of the literature.

The mutual dependence and indebtedness which exists between the so-called fundamental sciences and their clinical application is happily being recognized by both physiologists and practicing doctors. Prof. Henry C. Bazett closes the section on the circulation with the following words:

Physiology has something to contribute to medicine, particularly, perhaps, a scientific attitude, a meticulous attention to detail, and a more quantitative approach to the subject. But the contribution of medicine to physiology is no less important, for scientific medicine has contributed largely to the solution of the problem of vascular control in inflammation, to the study of excitation and conduction in the heart, and many other problems, sometimes in meticulous detail, sometimes in large outline of basic fundamental principles. When the pressing problem of hypertension is solved, it is as likely to be solved by the clinicians and to throw light on physiology, as it is to be solved by the physiologist and to throw light on medicine.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, APRIL 25

MONDAY APRIL 25

8 15 p m New England Heart Association Boston Medical Library
8 Fenway

TUESDAY APRIL 26

*9 10 a m Boston Dispensary Clinicopathological conference
Dr R. C. Wadsworth and Dr Cadis Plupps
*10 a m 12 30 p m Tumor clinic. Boston Dispensary
8 30 p m Clinicopathological meeting Cambridge Hospital

WEDNESDAY APRIL 27

*9 10 a m Boston Dispensary Hospital case presentation Dr
S J Thannhauser

STUDIES ON THE FAMILIAL ASPECTS OF CANCER

HERBERT L. LOMBARD, M.D.*

BOSTON

THE question of heredity as a predisposing factor to cancer has been a subject of interest to students of the cancer problem for several centuries. The first published opinion on this subject was Daniel Sennert's rejoinder to Zacutus Lusitanus, his seventeenth-century contemporary. Lusitanus evidently had stated that he had seen a case in which a girl had contracted cancer from her mother through hereditary "infection," and Sennert maintained that the disease could not be transmitted in this way.

Some cancer research workers feel that families in which multiple cancers have occurred furnish one proof for the hypothesis that cancer is hereditary, others assert that such findings are merely the phenomena of chance. A perusal of the literature yields several records of identical twins who had developed cancer. This has been presented as additional proof that cancer is hereditary. Innumerable physicians who occasionally have noticed cancer in two successive generations have felt that no further proof of the hereditary nature of cancer was necessary.

Animal experimentation has made possible the observation of morbid conditions in consecutive generations under ideal circumstances. Through close, long-continued inbreeding, strains of animals with a very large percentage of cancer among their offspring and strains with practically no cancer among their offspring have been produced. The fact that these results may be obtained more or less at will in expert hands under authentic laboratory conditions has convinced many that hereditary influence must be present in animals, and from this premise the assumption is made that the human race is similarly affected. Some individuals question any hereditary predisposition to cancer, others agree that there may be such a tendency and if the human race could be subjected to the eugenic selectivity of the laboratory, it could be demonstrated. Under the existing habits of the human race, inbreeding is such a relatively rare

phenomenon that a predisposition to cancer, based on heredity alone, becomes difficult to prove. Various statistical studies have been made, but their evidence is largely inconclusive.

The presentation to the public of this subject of heredity in cancer has been confused and inconsistent—on one occasion cancer is dogmatically stated to be a disease transmitted through heredity, on another it is specifically stated not to be transmitted in this way, on still another it is stated that for all practical purposes cancer is not hereditary. Heredity as an abstract phenomenon has no particular appeal, nor do the theoretical aspects of the case attract the interest of the general public. Whether an individual has a greater chance of developing cancer because a parent had the disease is the real problem.

With the full realization of the paucity of available material and of the obstacles inherent in the collection of statistical material of this kind, the Massachusetts Department of Public Health began seven years ago the collection of data with the intention of increasing the knowledge of this problem. An effort was made from the beginning to compensate for the statistical fallacies that were anticipated. Four approaches to the problem, which involved the use of two different sets of data, were made. The first set of data was obtained from the Massachusetts mortality records from 1841 to 1932. The second was taken from another study which dealt with the association between cancer and varied environmental factors.

In the first series of data, ten towns with a combined population in 1930 of 21,979 were selected. These communities were chosen because they were the type of community which had been conducive to permanent settlement and had witnessed the life span of generation after generation of the same families, and because over the period studied the quality of medical service had been high. Death records of all individuals above the age of twenty were copied. Family trees were constructed from these records. Each separate family tree listed

Health Under the "El" The story of the Bellevue Yorkville Health Demonstration in mid town New York
C E A Winslow and Savel Zimand. 203 pp New York and London Harper & Brothers, Publishers, 1937 \$2.25

In this book with illustrations, charts and tables, Winslow and Zimand describe the health demonstration that was conducted in the Bellevue Yorkville district of New York City over a ten year period. The area of this district was approximately 9 per cent that of the entire city, and the permanent population comprised a similar proportion. During the day a large influx of individuals from other localities came into the district and were subjected to some of the health hazards of the permanent residents. The demonstration was financed in part by the existing agencies and in part by a grant from the Milbank Foundation.

The objectives of the demonstration were

- 1 To apply to a given area known facts about the prevention of disease.
- 2 To interest the district in the improvement of its health
- 3 To further develop, by careful analysis and research, methods of public health administration that are practical and useful in a city of the first class.
- 4 To supplement existing health agencies, both public and private, to such an extent as to make their facilities reasonably adequate to meet the needs of the population. This implies a health program for the district that, if successful, may be applicable to the whole city and to other urban areas
- 5 To integrate the work of the demonstration so thoroughly with the Health Department and other agencies that the gains of the demonstration will be conserved after the demonstration itself is completed

At the close of the ten year period, substantial improvements in the health conditions of the district were noted. The tuberculosis rate had dropped, the typhoid rate had dropped, and no diphtheria cases occurred in 1933. Infant mortality showed a marked decline.

The practicing physician was considered in planning the demonstration. Dr Charles G Heyd said. It seems to me in a far larger sense the usefulness of the Bellevue-Yorkville demonstration has been that it is the first concrete example of the introduction of the medical profession into an ideal set up for health service.

Success of the projects planned to stimulate and aid in the practice of truly preventive medicine of the private physician was less complete than had been hoped. The graduate course offered to physicians in the technic of making general physical examinations was discontinued. The service of the contact worker who visited physicians in their offices to discuss with them ways of increasing their preventive practice was also discontinued. The general practitioners did not make use of laboratories which were made available to them to any great extent. Nurses were furnished to physicians to help them in furthering preventive work. Only a few physicians availed themselves of this service.

Winslow and Zimand state

What triumphed at Bellevue Yorkville was not merely an administrative technic, but an ideal, and an ideal by no means limited to the field of health. It was the basic ideal of democratic government.

In one sense, the Bellevue Yorkville demonstration was impermanent. Already, external evidences of its existence are passing. The personnel has been

scattered, the building may be converted to other uses. In its technical details, too, the work will pass.

In another sense, however, the work is lasting. Bellevue-Yorkville was not, after all, concerned mainly with introducing specific types of public-health work, with demonstrating the value of a particular method of procedure, a type of equipment. Its function was more basic. These changing, impermanent features were only the tools with which it worked—the means it used to carry out its fundamental purpose, which was, in its essence, an educational process for attaining an ideal of social co-operation.

One cannot help but wonder if this plan had taken into account to a far greater extent than it did the physicians in the district,—if it had been based more on the line of the Hunt plan,—if the results might not have been better.

Regardless of whether one is sympathetic with the undertaking, this book should be read by all students of medicosocial economic problems, as it offers one method toward their solution.

The Complete Pediatrician Practical, diagnostic, therapeutic and preventive pediatrics Wilburt C. Davison. Second edition 243 pp Durham, North Carolina Duke University Press, 1938 \$4.00

Here is a book small enough to carry easily in one's professional bag but which contains, nevertheless, about as much practical pediatric information as can be found in any book in the language. Included are discussions of some 329 diseases, 213 laboratory procedures and therapeutic technics, outlines of the principles of growth, development and child guidance and, for the less experienced, directions for history taking and the making of examinations.

But notwithstanding its comprehensiveness, its accuracy and its up-to-dateness this will not become every man's book. The arrangement of its matters is unusual and perhaps at first glance puzzling. And though no great effort is required to learn how to use it properly, there will be some (the reviewer is not including himself among the number) who will never learn to like it. Diseases are arranged in groups not on the basis of etiology but according to the anatomical system—respiratory, gastrointestinal, circulatory, neuropsychiatric, and so forth—through which their objective manifestations are most characteristically expressed. One in pursuit of a diagnosis proceeds from signs and symptoms to the disease and thence, it may be, to laboratory tests by which the diagnosis may be confirmed or rejected. In short, the approach is much the same as in using an index of differential diagnosis. If one be constitutionally inimical to such approach this book is emphatically not for him, if the method appeals he will come to value Dr Davison's work very highly.

The potential user should be assured in any case, however, that this second edition, entirely rewritten, is much easier to manage than was the first, the paragraph numbers have been reduced from some 1100 to about one fifth that number, thus greatly facilitating the pursuit of cross-references.

In preparing this book the author drew on no less than 7500 articles in various medical journals, but in order not to encumber the text with additional numbers the bibliography has been separately printed. It may be obtained from the publishers for fifty cents and may be inserted in the book at the option of the reader.

According to this method, if one cancer occurred in the family tree, there would be an 11.3 per cent probability of another case's occurring. The actual occurrence was 12.2 or a rate about 1 per cent greater than was expected.

The second type of data used was a part of a separate study dealing primarily with the association of various environmental factors and cancer. This study was financed in part by the Rockefeller Foundation. Histories were obtained from 249 women with cancer of the cervix and 250 with cancer of the breast, and from controls with similar age distributions. These women were all living and voluntarily had answered many questions regarding their life history. Only individuals willing to co-operate were included in the study. Each woman was questioned regarding the cause of death or sickness of grandparents, parents, brothers and sisters. Living relatives, unless they had been diagnosed by physicians as cancer patients, were classified as non-cancer, although the probability was recognized that some of them might later develop this disease. The information regarding grandparents was inadequate and the hereditary history was limited to the immediate family group, that is, the father, mother and children.

Of the 249 individuals with cancer of the cervix, 51 had either a parent or a brother or sister with cancer, while of the 249 controls, 44 had relatives with cancer. Of the 250 women with cancer of the breast, 53 had either a parent or brother or sister with cancer, while of the 250 women who were used as controls for this group, 43 had a parent or a brother or sister with the disease. The differences were not significant, but pointed in the same general direction as the other data.

CONCLUSIONS

All the methods used point toward some hereditary tendency to cancer. They do not indicate whether all cancer is hereditary. The statistical means at one's disposal makes this impossible. A general hereditary susceptibility may or may not be present. This study merely indicates that individuals among whose immediate relatives cancer has occurred have a slightly greater chance of contracting the disease than has the remainder of the population. The difference between the two groups is not sufficient to cause undue worry, but indicates, without any question, that further statistical studies on this problem are desirable.

100 Nashua Street.

PERITONEOSCOPY

EDWARD B. BENEDICT, M.D.*

BOSTON

PERITONEOSCOPY is the direct inspection of the abdominal and pelvic cavities by an endoscopic instrument. Cystoscopes have frequently been used for this purpose, and numerous modifications have been developed. Various names have been applied to the procedure, including celioscopy, ventroscopy, laparoscopy, organoscopy, abdominoscopy and splanchnoscopy. Although this examination is generally called *Laparoskopia* in Germany, here it is usually known as peritoneoscopy. In 1901, at the Seventy-Third Congress of German Naturalists and Physicians at Hamburg, Kelling¹ first demonstrated *Kölhoskopie* in a dog. He later used the method in human beings. From 1910 to 1914 Jacobaeus² published several papers on laparo-thoracoscopy, citing the usefulness of the method in cirrhosis, syphilis, Pick's disease, metastatic tumors and tuberculous peritonitis. In 1925 Nadeau and Kampmeier³ published a comprehensive review of the literature, briefly citing the experiences of some twenty authors from 1910 to 1925. Reference is also made to many of these writers by Ruddock,^{4, 5} who is chiefly responsible for the re-

cent revival of interest in this subject in the United States. Ruddock has examined over 500 cases by this method, and reports the peritoneoscopic accuracy of diagnosis as 91.7 per cent, as compared with a clinical accuracy of 63.9 per cent. Kalk⁶ has also written extensively on *Laparoskopia*, and although he points out the possible dangers of puncturing the bowel, injuring the viscera, infecting the peritoneum, spreading inflammatory processes and producing air emboli, he considers these possibilities to be very slight, reports no damage in 100 examinations, and concludes that the procedure is truly a "method without danger." Others who have written recently on the subject include Short⁷ (1925), Korbach⁸ (1927), Sweet⁹ (1927), Hanau¹⁰ (1932), Henning and Mancke¹¹ (1933), Fervers¹² (1933), Stolze¹³ (1934), de Laserna y Espina¹⁴ (1936), Anderson¹⁵ (1937) and Hope¹⁶ (1937). Anderson points out the possibility of (1) transillumination of the stomach, sigmoid, rectum and vagina, (2) implantation of radon needles and (3) electrocoagulation for sterilization of the female. Hope is enthusiastic about the use of peritoneoscopy in the differential diagnosis of ectopic pregnancy.

In a review of the literature we find that peritoneoscopy has been used in the following conditions:

*From the Massachusetts General Hospital.

*Assistant in surgery, Harvard Medical School and Massachusetts General Hospital.

the names of the ancestors, the date, age, and cause of death of all individuals found to have been members of that family

The total deaths at each ten-year age group and at each ten-year time interval were ascertained. The percentages of individuals that died of certain specified diseases were obtained. These percentages were applied to the individuals in the various age groups and time intervals to obtain an expected number of deaths for the causes studied. For example, the age group 60-69 in the time interval 1901-1910 would have for expected rates per unit—cancer 132, tuberculosis 050, heart disease .220, old age and ill defined 040, and all others .558—totaling 1. This represented the chance of dying of a given disease in a population of a given age group, all the members of which died in a given time interval.

Tabulations were then made showing the chance of dying of cancer or other diseases for all the known ancestors of individuals who had died of cancer. Similar tables were constructed for the ancestors of individuals dying of other causes. The summation of these tables furnished an expected number of deaths from various causes to be compared with the actual number of deaths from the various causes among ancestors of individuals with and without cancer. This method allowed for the grouping of data at different time intervals and age distributions, as well as the use of family trees of different lengths and structures.

The smallest family tree constructed consisted of one individual and one parent, the largest of the individual and twenty-three relatives. This method of classification made no allowance for collateral lines. A family tree started from the most recent death in a given line. There were some cases where two trees were almost identical because the initial individuals were brothers and sisters. The number of these was not great, for as a rule only one son or daughter remained in the native town. The record of one individual was counted as a cancer or non-cancer ancestor as many times as it occurred in this capacity, but was considered as the first person in a family tree only once.

	OBSERVED CANCER CASES	EXPECTED CANCER CASES
Known ancestors of cancer individuals	97.0	76.4
Known ancestors of non-cancer individuals	740.0	752.8
	OBSERVED CANCER RATES	EXPECTED CANCER RATES
Cancer rate per 100 among ancestors of cancer individuals	6.0	4.7
Cancer rate per 100 among ancestors of non-cancer individuals	4.7	4.6

Among the known ancestors of cancer individuals, the difference between the observed and the expected cancer cases showed significant positive association. A similar difference among ancestors of non-cancer individuals showed no significant

association. The expected cancer rates in the two populations were 4.7 and 4.6 respectively.* The observed cancer rate among ancestors of non-cancer individuals, 4.7, was consistent with the expected, but the observed rate among ancestors of cancer individuals, 6.0, was significantly greater. This method, which gives corrections for both the time element and the age factor, indicates that the rate is slightly over 1 per cent higher among ancestors of cancer individuals than would be expected.

Another method used in the analyses of these data was a computation of the percentage of known cancer children in families in which one or both of the parents had cancer. In this part of the study an additional community, with a population in 1930 of 8668, was added. The family trees were constructed in the same way as in the previous study, but the computations previously discussed were omitted due to the time element and the conviction that sufficient evidence of this type had been used.

Of 1129 families, one parent of whom had cancer, 10.5 per cent of the known children in the family trees had cancer. In 6741 families in which neither parent had cancer, the cancer rate among known offspring was 8.6 per cent. The difference between 10.5 and 8.6 indicates a cancer rate about 2 per cent higher among individuals with cancer parents than among those without the disease. In twenty-three families in which both parents had cancer, 13.0 per cent of the known children had cancer. The rate for families in which cancer occurred in both parents is based on a small population and is not well fixed. Still, it may point toward the possibility of a higher rate among such families.

Of the children of parents who had cancer, 12.6 per cent had a cancer of the same site as the parent, 29.5 per cent had cancer of a different site, and the sites were unknown in the remaining 57.9 per cent. The large number of unknowns was primarily due to the presence on the death certificate of the word "cancer" with no notation as to site. The large number of unknowns invalidates these figures, but when it is considered that 30 per cent of the children of cancer parents where the site was known had cancer of the same site, and 70 per cent had cancer of a different site, there is a possibility that site of cancer is of importance.

The application of the binomial expansion to family trees of various sizes, using the cancer rate for each group of families, was another method used on these data. The expected number of cancers found in the total summation was compared with the actual and showed that multiple cancers were found slightly more often than would have been expected by a purely chance phenomenon.

The norm of 4.6 or 4.7 per cent is of course much lower than the present-day figure. This is due to the changing ratio over the years. The ratios in this study closely agree with those of Massachusetts on a year by year basis.

mors, ectopic pregnancy and ovarian dysfunction. In one case an excellent view was obtained of a polycystic liver, in another case of supposed echinococcus cyst, the liver was found to be normal, and in a third case where there was a questionable palpable mass, the peritoneal cavity was found to be normal.

Contraindications. Serious cardiac or pulmonary disease may be a contraindication, for the peritoneal distention necessary for a satisfactory examination may somewhat embarrass the circulation and the diaphragmatic movements. Numerous abdominal adhesions may constitute a contraindication, though it is usually possible to select a site for puncture at a safe distance from previous laparotomy scars. Because of the danger of spreading infection, peritoneoscopy is contraindicated in inflammatory conditions.

Relative Advantages of Peritoneoscopy and Exploratory Laparotomy. Peritoneoscopy is a minor procedure performed under local anesthesia through a 1 cm incision, requiring only one day's hospitalization and involving very little risk or discomfort. Exploratory laparotomy is a major operation usually performed under general anesthesia through a 12- to 15-cm incision, requiring ten to fourteen days' hospitalization and involving considerable risk and discomfort to the patient. Biopsy can be obtained by either method. Exploratory laparotomy has the advantage of giving a more thorough examination, including palpation as well as inspection, and also of permitting the completion of whatever operative procedure may be indicated. Peritoneoscopy, however, is a very much simpler procedure, and although it has limitations there are many cases in which it is definitely preferable.

The following cases are typical of those in which we have found peritoneoscopy a valuable diagnostic procedure.

Case 1 P. D. (M. G. H. No. 352746), a 55-year-old widowed American housekeeper, entered the hospital on April 12, 1936, with a chief complaint of pain in the right side. For 5½ weeks she had experienced dull right upper quadrant and epigastric pain, associated with gaseous eructations and intermittent attacks of nausea and vomiting. There was a history of cholecystectomy 10 years previously and pernicious anemia of 6 years' duration, treated with liver with indifferent success. On physical examination the patient appeared weak and was sallow. Abdominal palpation showed a firm, smooth, tender mass filling the epigastrium. The liver edge was smooth, firm and tender, 4 fingerbreadths below the costal margin. The patient was considered a poor risk for anesthesia. X-ray examination had been performed at the onset of the present illness at a local hospital, and was said to have shown a neoplasm of the stomach.

Peritoneoscopy showed large, elevated nodules in both lobes of the liver (Fig. 1), having the gross appearance

of carcinoma. A biopsy was obtained from one of these nodules, which on pathological examination showed metastatic carcinoma.

Comment. This patient, weakened by pernicious anemia and probable cancer of the stomach, was in no condition to withstand an exploratory laparotomy, which carries a very high mortality in such a combination of circumstances. By the relatively simple operation of peritoneoscopy the liver was found studded with nodules, a positive biopsy of

Figure 1 Case 1 Carcinomatous nodule of liver as seen through the peritoneoscope. A positive peritoneoscopic biopsy was obtained from this nodule.

metastatic carcinoma was obtained and the patient was saved a surgical exploration.

Case 2 G. D. M. (U. No. 5311), a 55-year-old Italian laborer, entered the hospital on October 31, 1936, with a chief complaint of epigastric distress. He gave a history of epigastric distress with nausea and belching for the last 2½ years, relieved by food and soda until 6 months previously, when the distress appeared with food and was not relieved by soda. There was no vomiting, but there had been a loss of 40 lb in the past 8 months. Physical examination was essentially negative except for a 2 by 3 cm. mass in the epigastrium. X-ray examination showed an annular filling defect of the antrum of the stomach, consistent with carcinoma.

Peritoneoscopy showed the liver and peritoneum throughout to be free of metastatic cancer (Fig. 2). Operation was therefore undertaken the next day, the peritoneoscopic observations were confirmed, and the gastric lesion was resected. Pathological examination showed it to be carcinoma of the stomach with metastases to regional lymph nodes. The patient made a good recovery, went home, gained weight and strength for several months but eventually failed and died of recurrence about 5 months after the operation.

In this hospital we have been using the Ruddock peritoneoscope for two years, and have made 48 examinations. There has been 1 fatality, in which the pneumoperitoneum may well be considered as a contributory cause of death. The patient was in the terminal stages of multiple lung abscess, coronary disease and possible echinococcus cyst of the liver. An error in judgment was made in subjecting him to the stress and strain of sedative drugs and peritoneoscopy. There have been no other complications except a subcutaneous emphysema in a few cases. No real errors in diagnosis have occurred, though in 1 case in which the liver appeared normal on the surface it was found by palpation at laparotomy to be full of nodules. This possibility, however, had been mentioned in the peritoneoscopic report, for the examiner had been suspicious of a smooth swelling on the surface of the liver.

Instrument We have found the Ruddock peritoneoscope satisfactory, and have used it in all except the first few examinations, when we used a thoracoscope. Ruddock has described the instrument in detail, with illustrations. It consists essentially of a very small, blunt trocar for obtaining pneumoperitoneum, and a sheath into which may be inserted a large, blunt obturator, an observation telescope or a biopsy forceps. The telescope and biopsy forceps each fit the sheath when the obturator is removed. The biopsy forceps is equipped with a small telescope so that biopsies can be taken under direct vision. A diathermy connection permits the coagulation of bleeding points. Air may be introduced at any time through the sheath.

Technic The patient is prepared as for laparotomy, including abdominal shave and scrub, fasting stomach, empty bladder and preliminary sedation with barbiturates and morphine. The instrument is sterilized in the formalin cabinet. The surgeon and his assistant observe the same aseptic precautions as for any abdominal operation. The

usual site of puncture is in the midline just below the umbilicus, but other sites may be advisable when lower abdominal adhesions or tumors are suspected. Novocain is injected into the area selected, the skin and subcutaneous tissues being infiltrated down to the peritoneum. A small stab incision is then made through the skin and fascia, and the small blunt trocar is introduced into the peritoneal cavity, care being taken not to direct it toward the vertebrae because of the danger of compressing and injuring the viscera. The peritoneal cavity is then inflated with air with an ordinary hand bulb. Failure to introduce the trocar deeply enough may result in accidental inflation of the subcutaneous tissues with air. Such an emphysema, while not to be desired, has never caused any trouble in our experience. Having obtained a good air space it is safe to introduce the large trocar into the peritoneal cavity. The obturator is then removed from the sheath and the telescope is inserted in its place. The secret of success in peritoneoscopy lies in having a large peritoneal air space so as to assure satisfactory visualization. The examination of the abdomen and pelvis should be carried out systematically. The Trendelenburg position and other changes of position may be very helpful in exposing the various organs to be examined. Rectal or vaginal palpation by an assistant may aid in exposure. Another assistant should be present to watch the patient's pulse, respiration, blood pressure and general condition.

Dangers When patients are carefully selected, peritoneoscopy is attended with very little risk. Those with serious pulmonary or cardiac disease are not good prospects. Abdominal adhesions may complicate the procedure, but by careful selection of the site of puncture difficulties have thus far been avoided. Ruddock, however, reports 8 punctures of the bowel in 500 cases. In each of these the instrument was left in place and an abdominal incision was made, which revealed that the trocar could have been removed without soiling the peritoneal cavity, for in every case the bowel was firmly adherent to the parietal peritoneum. Ruddock also records 1 death from hemorrhage following biopsy of a carcinomatous nodule in the liver. He believes that this could have been avoided by more thorough coagulation of the biopsy wound.

Indications Peritoneoscopy may be indicated in any abdominal or pelvic condition where the diagnosis is obscure, or where additional evidence is needed to confirm a diagnosis or to plan treatment. The procedure will frequently give information that will decide for or against laparotomy. We have found peritoneoscopy useful in cancer, cirrhosis, tuberculous peritonitis, ascites, pelvic tu

mors, ectopic pregnancy and ovarian dysfunction. In one case an excellent view was obtained of a polycystic liver, in another case of supposed echinococcus cyst, the liver was found to be normal, and in a third case where there was a questionable palpable mass, the peritoneal cavity was found to be normal.

Contraindications. Serious cardiac or pulmonary disease may be a contraindication, for the peritoneal distention necessary for a satisfactory examination may somewhat embarrass the circulation and the diaphragmatic movements. Numerous abdominal adhesions may constitute a contraindication, though it is usually possible to select a site for puncture at a safe distance from previous laparotomy scars. Because of the danger of spreading infection, peritoneoscopy is contraindicated in inflammatory conditions.

Relative Advantages of Peritoneoscopy and Exploratory Laparotomy. Peritoneoscopy is a minor procedure performed under local anesthesia through a 1 cm incision, requiring only one day's hospitalization and involving very little risk or discomfort. Exploratory laparotomy is a major operation usually performed under general anesthesia through a 12- to 15-cm incision, requiring ten to fourteen days' hospitalization and involving considerable risk and discomfort to the patient. Biopsy can be obtained by either method. Exploratory laparotomy has the advantage of giving a more thorough examination, including palpation as well as inspection, and also of permitting the completion of whatever operative procedure may be indicated. Peritoneoscopy, however, is a very much simpler procedure, and although it has limitations there are many cases in which it is definitely preferable.

The following cases are typical of those in which we have found peritoneoscopy a valuable diagnostic procedure.

Case 1 P D (M. G. H. No. 352746), a 55-year-old widowed American housekeeper, entered the hospital on April 12, 1936, with a chief complaint of pain in the right side. For 5½ weeks she had experienced dull right upper quadrant and epigastric pain, associated with gaseous eructations and intermittent attacks of nausea and vomiting. There was a history of cholecystectomy 10 years previously and pernicious anemia of 6 years' duration, treated with liver with indifferent success. On physical examination the patient appeared weak and was sallow. Abdominal palpation showed a firm, smooth, tender mass filling the epigastrium. The liver edge was smooth, firm and tender, 4 fingerbreadths below the costal margin. The patient was considered a poor risk for anesthesia. X-ray examination had been performed at the onset of the present illness at a local hospital, and was said to have shown a neoplasm of the stomach.

Peritoneoscopy showed large, elevated nodules in both lobes of the liver (Fig. 1), having the gross appearance

of carcinoma. A biopsy was obtained from one of these nodules, which on pathological examination showed metastatic carcinoma.

Comment. This patient, weakened by pernicious anemia and probable cancer of the stomach, was in no condition to withstand an exploratory laparotomy, which carries a very high mortality in such a combination of circumstances. By the relatively simple operation of peritoneoscopy the liver was found studded with nodules, a positive biopsy of

Figure 1 Case 1 Carcinomatous nodule of liver as seen through the peritoneoscope. A positive peritoneoscopic biopsy was obtained from this nodule.

metastatic carcinoma was obtained and the patient was saved a surgical exploration.

Case 2 G D L (U No. 5311), a 55-year-old Italian laborer, entered the hospital on October 31, 1936, with a chief complaint of epigastric distress. He gave a history of epigastric distress with nausea and belching for the last 2½ years, relieved by food and soda until 6 months previously, when the distress appeared with food and was not relieved by soda. There was no vomiting, but there had been a loss of 40 lb in the past 8 months. Physical examination was essentially negative except for a 2 by 3 cm. mass in the epigastrium. X-ray examination showed an annular filling defect of the antrum of the stomach, consistent with carcinoma.

Peritoneoscopy showed the liver and peritoneum throughout to be free of metastatic cancer (Fig. 2). Operation was therefore undertaken the next day, the peritoneoscopic observations were confirmed and the gastric lesion was resected. Pathological examination showed it to be carcinoma of the stomach with metastases to regional lymph nodes. The patient made a good recovery, went home, gained weight and strength for several months but eventually failed and died of recurrence about 8 months after the operation.

Comment Because of the long history, the large amount of weight loss and the palpable mass, it was believed on clinical examination that the lesion was very likely inoperable. Peritoneoscopy, however, showed a normal liver and peritoneum. Operation was therefore undertaken and the growth removed. Although this patient died of recurrence

Figure 2 Case 2 Appearance of normal liver and gall bladder

eight months later, he was given a considerable period of comparative symptomatic relief.

Case 3 A. G. C. (U No 92031), a 54-year-old Italian housewife, entered the hospital on November 27, 1937, because of swelling of the legs. Twenty-seven years previously, edema of the legs appeared during the first pregnancy, disappearing after delivery but recurring with each of five subsequent pregnancies. The edema had been persistent for the past 5 years. Five years previously the patient had experienced an attack of jaundice, fever, epigastric distress and vomiting. Similar attacks had recurred on four or five occasions. The past history was noncontributory except for daily intake of beer. On physical examination the patient was moderately obese, with slightly pale mucous membranes and a muddy complexion. The heart and lungs were negative. On abdominal palpation there was mild epigastric tenderness. The liver edge was smooth and non-tender, and descended 4 fingerbreadths below the costal margin on inspiration. The spleen was palpable and of firm consistence, and was felt 2 or 3 fingerbreadths below the costal margin. The extremities showed pitting edema of both lower legs, the right leg being larger than the left. The urine was negative. The red-cell count was 1,780,000, with a hemoglobin of 45 per cent. The white-cell count was 2300, with polymorphonuclears 56 per cent, lymphocytes 42 per cent and large mononuclears 2 per cent. The red cells were larger than normal, and showed some stippling. The reticulocyte count was 58 and 86 per cent on two occa-

sions. Sternal puncture showed active red-cell formation. The fragility was normal. The liver function test was 12 per cent retention in 30 minutes. X-ray examination showed a large spleen and a small liver consistent with cirrhosis. On Graham test a few small calcified stones were seen in the gall bladder, which filled normally with the dye.

Administration of liver extract was started, but there was no response. Three transfusions were given, with improvement. Because of the failure of liver extract to raise the red-cell count, and because of constant reticulocytosis without any therapy, the anemia was considered to be at least partially hemolytic, and splenectomy was

Figure 3 Case 3 Typical appearance of small, cirrhotic, hobnail liver

believed indicated. Many of the staff, however, were not enthusiastic about splenectomy and considered the patient a poor risk. Peritoneoscopy was therefore suggested.

Peritoneoscopy showed the liver to be extremely small and granular, in fact almost nodular and hobnailed (Fig 3). All observers agreed that it was typically cirrhotic.

Comment Peritoneoscopy in this case established a positive diagnosis of advanced cirrhosis of the liver, which contraindicated the proposed splenectomy.

Case 4 A. R. K. (U No 45885), an 89-year-old Canadian widow, entered the hospital on December 31, 1937, because of right lower-quadrant pain. Nineteen days before entry she began to have a dull ache in the right lower quadrant and over the symphysis, especially when lying on her back or turning over in bed. There had also been frequency, urgency, polyuria and nocturia. There was moderate anorexia, gaseous distention and constipation. Physical examination showed a mass in the lower abdomen, chiefly on the right side, and difficult to outline. Over this region there was well localized tenderness and spasm. The temperature was 98.6 F, the white cell count was 8400.

Appendiceal abscess and neoplasm of the ovary, uterus or bowel were both considered in the differential diagnosis. As the tenderness subsided and the temperature

Figure 4 Case 4 Large, benign-appearing ovarian cyst in a patient eighty-nine years of age

remained normal, the diagnosis of abscess was abandoned and the process was presumed to be noninflammatory. Peritoneoscopy was advised.

On peritoneoscopy (January 5, 1938) there was seen a bluish-gray mass consistent with a large, benign ovarian

Figure 5 Case 4 Aspirating trocar plunged into an avascular area in the cyst under direct peritoneoscopic vision

cyst occupying the entire right lower quadrant and extending slightly to the left of the midline and above the umbilicus (Fig 4). It was very smooth in outline, apparently nonadherent and definitely translucent.

A probable diagnosis of benign ovarian cyst having been established, the possible choices of therapy were considered. With no treatment at all this woman would have been left with a cyst which was apparently giving definite symptoms. Laparotomy through a long incision, with removal of the large unruptured cyst, was considered hazardous and unjustifiable in a woman of this age. Laparotomy through a small incision, with puncture of the cyst and removal of the cyst wall, was also rejected as somewhat hazardous and unsatisfactory. Blind tapping of the cyst through the abdominal wall was considered dangerous, as the trocar might enter the bowel or puncture a blood vessel. Aspiration of the cyst under direct peritoneoscopic vision was felt to be the ideal procedure.

Figure 6 Case 4 Resultant collapse of the cyst

Accordingly, peritoneoscopy was again performed (January 7, 1938). The peritoneoscope was introduced through the incision previously used (in the midline just above the umbilicus), and a long trocar was inserted through the abdominal wall in the right lower quadrant. Under direct vision through the peritoneoscope this was seen to enter the abdominal cavity near the cyst. An avascular area in the cyst wall was then selected and the trocar was plunged deeply into the cyst (Fig 5), suction was applied, and 520 cc. of clear, thin, straw-colored fluid was aspirated, with resultant collapse of most of the cyst (Fig 6). The temperature remained absolutely flat following both peritoneoscopies. Because of the patient's age she was kept in the hospital a little longer than usual, but was discharged home improved 5 days after peritoneoscopy.

Comment While we do not recommend this form of therapy for ovarian cysts, it so happened that it was admirably suited to meet the problem presented by this patient in her ninetieth year.

Case 5 M E B (M G H No 355031), a 69 year-old, single American woman, entered the hospital on July 23, 1936, because of vomiting and a 30-lb weight loss of 3 months duration. Two months previous to admission she noticed a large, painless lump in the right abdomen. On physical examination the abdomen was markedly distended and rather tense, with fluctuation of the lower portion. A firm, rather irregular, moderately tender mass was palpated in the lower abdomen. Rectal examination showed several fixed, irregular nodules behind the cervix.

At peritoneoscopy, after removal of 250 cc. of straw-colored fluid, the entire lower abdomen was seen to be occupied by a large, smooth, pearl gray mass, from which a biopsy was obtained. The anterior peritoneum appeared to contain metastatic nodules. The pathological report was metastatic carcinoma. A series of x-ray treatments was given.

Comment In this case, peritoneoscopy established a positive diagnosis of carcinoma, probably of ovarian origin, and enabled the x-ray department to carry out an intelligent plan of x-ray therapy.

Case 6 G H. (U No 88618), a 23-year-old single, American-born truck driver of Syrian extraction, entered the hospital on October 29, 1937, complaining of progres-

Figure 7 Case 6 Tuberculous peritonitis with multiple adhesions peritoneum studded with tubercles

sive swelling of the abdomen of 3 months duration, with a 15-lb weight loss. Physical examination showed marked scoliosis, a full, rounded abdomen, suggesting fluid but without much positive physical evidence, and a slight splenomegaly. X-ray examination demonstrated scoliosis, with tuberculosis of the right upper lobe (clinically inactive).

On peritoneoscopy the abdominal cavity was found to be completely filled with numerous filmy adhesions, on some of which were many pin point tubercles (Fig 7). Only a small amount of fluid (100 cc.) could be removed.

Comment In this case the differential diagnosis was between neoplasm with ascites, Banti's disease and tuberculous peritonitis. From the point of view of treatment, a positive diagnosis was important. Peritoneoscopy established the diagnosis of tuberculous peritonitis.

Case 7 C McC (U No 92925), a 29 year-old, white, American housewife, entered the hospital on November 18, 1937, because of vaginal bleeding. Eighteen days before entry the patient missed her normal menstrual period, experienced morning vomiting for a few days and noted swollen, tender breasts. On three occasions during the

Figure 8 Peritoneoscopic view of a normal uterus, part of the left tube and part of a somewhat enlarged left ovary

past 8 days she had suffered bilateral lower abdominal cramps, with moderate vaginal bleeding. She had been married 9 years, but had had no pregnancies. On physical examination the abdomen showed diffuse tenderness in the left lower quadrant. Vaginal examination disclosed a soft cervix, dilated external os, slightly enlarged, soft fundus, and a tender, movable, walnut sized mass in the left vault. There were possible lesions in the right vault. The Aschheim Zondek test was positive.

Peritoneoscopy (November 19, 1937) showed free blood in both anterior and posterior cul-de-sacs. The fundus of the uterus appeared normal in size and color. The distal end of the right tube was distended so that it appeared to be about 6 cm in diameter. The proximal end of the left tube appeared normal, but the distal end was not recognized. On the basis of the hemoperitoneum and the mass in the right tube, a diagnosis of ectopic pregnancy with right hematosalpinx was made. Operation confirmed the peritoneoscopic findings of hemoperitoneum and a cystic mass in the right tube. The ectopic pregnancy, however, was in the distal end of the left tube.

Comment The clinical diagnosis in this case was a question of ectopic pregnancy. The demon-

stration of hemoperitoneum by peritoneoscopy made the diagnosis of ectopic pregnancy a positive one.

Case 8 R. T. (U No 92127), a 32-year-old, single, American woman, entered the hospital on November 22, 1937, because of amenorrhea. Although the catamenia were normal and regular every 28 days from the time the patient was 11 years old until she was 19, her periods suddenly stopped at that time, and except for one normal period at the age of 20 she had not flowed again. Except for nervousness, occasional hot flashes and mental depression, the patient had been in good health. Physical examination showed normal secondary sex characteristics. Pelvic examination revealed a marital introitus, a small nulliparous cervix and the fundus probably in second-degree retroversion.

On peritoneoscopy the uterus was clearly seen to be in normal position and of about two-thirds normal size. Both ovaries were small and atrophic, with no evidence of recent scarring or of follicle or corpus-luteum formation.

Comment In this case, peritoneoscopy disclosed a small uterus with atrophic ovaries. The positive information thus obtained was inductive to intelligent therapy by the Ovarian Dysfunction Clinic.

CONCLUSIONS

Peritoneoscopy is the direct inspection of the abdominal and pelvic cavities by an endoscopic instrument. A satisfactory biopsy can be obtained.

In properly selected cases it is safely and easily performed under local anesthesia, with little discomfort to the patient.

Peritoneoscopy will not replace exploratory laparotomy in all cases, but in certain cases it makes it possible to avoid major surgical operations. Whereas surgical exploration usually involves general anesthesia, long incision, two weeks' hospitalization and considerable risk, peritoneoscopy re-

quires only local anesthesia, a stab incision, one day's hospitalization and very little risk.

Peritoneoscopy may be indicated in any abdominal or pelvic condition where the diagnosis is obscure or where additional evidence is needed to confirm a diagnosis or to plan treatment. It is contraindicated when there is serious cardiac or pulmonary disease, and when there are inflammatory processes or many adhesions in the peritoneal cavity. We have found the procedure of value in abdominal cancer, cirrhosis, tuberculous peritonitis, ascites, pelvic tumors, ectopic pregnancy and ovarian dysfunction.

PAPERS FROM THE FAULKNER HOSPITAL

THE CONDITION OF THE CERVIX AS DETERMINED BY VAGINAL EXAMINATION

A True Index of the End of Pregnancy

RAYMOND S. TITUS, M.D.*

MEDICAL teaching twenty-five years ago was opposed to vaginal examinations late in pregnancy, and the teaching today has changed very little in this regard. Inherited fear of infection by vaginal examination is, of course, the reason for this attitude, and it must be acknowledged that many cases of puerperal sepsis have been avoided by strict adherence to this dictum. However, so long as the patient is neither bleeding nor in labor, in other words presents no raw surface through which infection may enter, the chances of infection are negligible and are far outweighed by the information which is gained by means of the procedure. Only by its use can the changes in the cervix that immediately precede the onset of labor be appreciated, and since these changes are essential to the proper management, particularly in the induction of labor, in many cases of pregnancy, their recognition is extremely important.

The acquisition of the information contained in this communication has been slow in accumulation. For twenty-odd years observations have been made. The extremely rapid termination of pregnancy in one case after therapeutic induction of labor in contrast to the delay in another was puzzling. Both patients might be at the same time of their pregnancies according to dates, and yet one labor might be extremely easy, absolutely normal and uncomplicated, while another might be delayed for two or three days. The quest of ascertaining why these differences existed led to vaginal examinations, and has resulted in the information later on described.

In this communication something is said of elective induction of labor. This paper is no brief for this procedure. Such cases are referred to only because of the information they furnish in regard to the changes in the cervix. Elective induction of labor is a major obstetrical performance and should be performed only by the well-trained and experienced obstetrician, but it must be appreciated that the acquisition of the knowledge upon which proper criteria for elective induction are based has also furnished the data for the recognition of the changes that occur in the cervix during the last month of pregnancy.

In the past twenty-five years there have been

several very important advances in clinical obstetrics. Rectal examinations during labor are so much of an advance that they should be universally adopted, and it is surprising that they are not. They certainly should take the place of almost all vaginal examinations. Routine episiotomy is a procedure the benefits of which entitle it to be classed as a true step in advance. Fundal pressure has done away with many forceps operations. Analgesia has reached a state where in trained hands it is almost perfect. But no advance has been so important, has so lowered the fetal and maternal mortality and maternal morbidity, as an appreciation of the dangers of delivery through the physiologically unprepared cervix.

Twenty-five years ago the cervix during labor received little or no consideration. In cases in which immediate delivery seemed necessary, delivery was accomplished by the vaginal route, irrespective of the condition of the cervix. The results too often included badly mutilated cervixes, postpartum hemorrhages, ruptured uteri and high fetal and maternal death rates. During this era patients with placenta previa, severe toxemia or eclampsia were routinely delivered through the undilated cervix, and many maternal deaths were attributed to these complications which were due solely and entirely to the operative procedure.

But has our knowledge about the normal cervix in the last weeks of pregnancy increased beyond what we knew twenty-five years ago? Much more is known, but this is not generally appreciated. The teaching of obstetrics has not stimulated the acquisition of a knowledge of the cervix, because it has long been an axiom that the vagina should be left alone in the latter months of pregnancy, that vaginal examinations should be done only when some indication made it necessary—not as a routine procedure. Undoubtedly, inherited fear of infection has entered into this teaching. This fear is probably groundless, for, in view of human nature and human weakness, it is reasonable to infer that the vagina is invaded quite often through intercourse in the last few weeks of pregnancy, and it seems unreasonable to believe that the invasion of the vagina, with a sterile glove, of a person not in labor will cause infection.

If we are to learn of the cervix late in pregnancy, the cervix must be felt. In no other way can one know its normal changes. We learn by

touch If we do not examine patients routinely and frequently in the last few weeks of pregnancy, we cannot appreciate what normal changes take place. Whether we believe in elective induction or not, it has, by necessitating frequent vaginal examinations in an attempt to determine when the time for induction is ripe, been responsible for our knowledge of the normal, physiologic changes of the cervix late in pregnancy

For one reason or another, inductions were formerly done on certain cases by rupturing the membranes, because the results in other cases that had had to be induced had been so successful. At that time dates alone were the criteria as to when this should be done. Experience showed that dates were not a constant, safe indication. Some of these patients had their babies quickly. Others would not start in labor for thirty-six or forty-eight hours, and although they all came along successfully, some of them undoubtedly had harder and longer labors than were necessary. Each of the rapid cases stimulated further investigation and brought up the question why some were delayed. To ascertain these reasons routine vaginal examinations at weekly intervals after the eighth month were instituted. One must appreciate that hundreds of such examinations were done, and it was not until a great many had been made that it became clear that as these patients approached the end of their pregnancies the cervixes became obliterated, soft, and patulous in varying degrees, and the internal osar became soft. When these conditions were present, it was realized that the patient was ready to be induced, and these are the criteria upon which an intelligent induction is based. There are no other criteria! The corollary is that the unobliterated, unopened cervix almost invariably means that the end of pregnancy has not yet been reached.

The patient who is within a week or so of her expected date, who starts up spontaneously and who has a baby normally within two or three hours is really ready to have her baby, and the same is true of the patient whose baby arrives anywhere from one-half to four hours after the induction of labor. But when one realizes that the latter was induced because the cervix was soft, obliterated and dilated, one must admit that the cervix was an index of the end of the pregnancy. May it not be said, irrespective of dates, that that particular person was at the end of her journey? And then when it is pointed out that occasional patients have been examined for one reason or another as early as three weeks before the expected time of labor whose cervixes were found to be flat, soft and patulous, who began labor within a few days, whose babies arrived within

one and a half hours of the onset of labor, whose babies weighed as much as or more than the previous babies of these same patients, will it not then be admitted that the cervixes in these cases showed that the end of pregnancy was at hand? And then when other cases are demonstrated that were examined week after week for four weeks after the expected end of pregnancy and still had firm and undilated cervixes, will it not be admitted that the cervix is a better index of the end of pregnancy than any other index we now have? And, lastly, when patients whose dates for elective induction had been definitely set because of the condition of the cervixes started up spontaneously within twenty-four hours of this settled date, will this not be a proof that one can tell by the cervix when the end of pregnancy is around the corner? These questions will be answered in the cases to be demonstrated.

Four hundred and forty-seven deliveries by the vaginal route are the basis of this paper. Of these, 138 were induced electively by the rupture of the membranes. Thirty-two more started up spontaneously after a date had been set for their inductions.

It is impossible to say how many vaginal examinations were made on these patients, but undoubtedly there were a great many. Is the vaginal examination a safe procedure? Does it cause infection? The answer is that in this series there were two cases of infection. One started five days after delivery and was due to a hemolytic streptococcus, the patient ran a fever for five days only. The second case was that of a patient who had been infected with gonorrhea during her pregnancy, was not examined in the office before labor, and was delivered normally.

As to the technic of these vaginal examinations, the patient is examined with a sterile glove, which is moistened with a 1:20 dilution of Lugol's solution to make the examination more comfortable for the patient. The vulvae should be gently cleansed with soap and water and rinsed with the dilute iodine solution.

If vaginal examinations are to be done routinely late in pregnancy, they must not only be safe but they must also be done for a purpose. What do they teach? In the first place, they teach the physician to recognize the normal changes that go on week by week in the cervix toward the end of pregnancy, and in no other way can these changes be appreciated. Secondly, they show that the majority of patients have obliterated, soft, open cervixes before they start in labor, and that it is the unusual case that starts in labor with an unobliterated firm, undilated cervix. These facts are of value both to the physician and to

the patient, particularly one living in the country. If the examination shows an unobliterated, firm, undilated cervix, it is perfectly safe for the patient to return home. When such a patient starts up spontaneously in labor we know that the cervix will require a long while to take up and dilate. This is important information. More intelligent handling of the case, if labor starts, is possible. If, on the other hand, examination shows a cervix that is entirely obliterated and open, the patient should remain in town within easy distance of her hospital. Thirdly, vaginal examinations by those who believe in elective induction will show definitely whether the individual case is ready to be induced. Fourthly, they give a very definite idea of when the time for delivery is at hand in patients whose periods are not to be relied upon. All these facts are well worth while from the obstetrician's point of view and often from the standpoint of the patient.

In reviewing these cases no definite tabulation has been attempted. However, the longest labor was ten hours, the shortest eighteen minutes, and the average duration was from three to five hours. There were no complications, there were no prolapses of the cord, there were no postpartum hemorrhages, and no babies were lost. The following cases illustrate one or more of the above points.

Case 1 (No 2509) Para III. This patient was due on dates on May 27-30. On May 4, vaginal examination showed an engaged vertex and an almost flat cervix, dilated one finger plus. One week later, the cervix was two fingers dilated, flat and soft. She was induced on May 14, when she was 2 weeks early on dates. The membranes were ruptured at 8:45 in the morning and the baby was delivered normally 1 hour and 20 minutes later. This baby weighed 7 lb, 6 oz, and a previous baby had weighed 7 lb, 12 oz.

This case proves by the duration of the labor and the size of the baby that the patient was at the end of her pregnancy even though the expected date, as ordinarily computed, was two weeks away.

Case 2 (No 2975) Para II. This patient was due on dates on November 17-20. Examination on October 21 showed the cervix to be entirely flat, one finger dilated. She lived 25 miles from Boston. Her previous baby was premature and weighed 5 lb, 12 oz. Her membranes were ruptured at 8:50 a. m. and the baby was born at 9:15 a. m. This baby weighed 6 lb, 9 oz, and in no way looked premature.

Examination of the cervix in this case showed that labor was imminent approximately four weeks before the computed time. The duration of the labor and the size of the baby bore out this inference.

Case 3 (No 2774) Para I. This patient was 41 years

old and was due on dates on October 14-17. She was seen in the office on October 1, at which time vaginal examination showed an engaged vertex and an absolutely flat cervix. Vaginal examination again a week later showed a flat cervix, dilated one finger. The patient went into the hospital that night. Her membranes were ruptured at 8:45 a. m., and a simple forceps was done to a crowning head shortly after 2:00 p. m. The baby weighed 8 lb.

Case 4 (No 2375) Para I. This patient was 40 years old and was due on dates June 10-13. Vaginal examination on May 31 showed the cervix to be entirely taken up, dilated one finger, with a tight internal os. On June 7 vaginal examination showed the cervix to be entirely flat, and the internal os dilated one finger. Membranes were ruptured about 9:00 a. m. on June 12, and the baby was delivered shortly after 1:00 p. m. The baby weighed 7 lb, 6 oz.

These two cases show that by the examination of the cervix, combined with a knowledge of the changes taking place late in pregnancy, it is possible to predict a relatively easy labor.

Case 5 (No 3037) Para III. This patient was due on dates on January 4-7. She lived out of town and was not seen during her pregnancy. Vaginal examination on December 26 showed no obliteration of the cervix, it was dilated one finger and firm. A note made at that time reads, "This patient will go three weeks." On January 2 the cervix showed no change from the previous visit. On January 9, a note reads, "Cervix still only one finger, tight, not obliterated, and if labor starts, it will be long." Three days later the patient started up spontaneously and had a very hard labor. Pains 3 or 4 minutes apart over a period of 10 hours were required to deliver normally a child weighing 8 lb, 14 oz.

An appreciation of the difficulty that a patient, going in labor with a cervix of this type may experience is of value to the obstetrician.

Case 6 (No 2959) Para I. This patient was 28 years old and was due on dates on November 8-11. Vaginal examination on October 27 showed the cervix to be posterior and not taken up. Vaginal examination on November 3 showed that the head was not in the pelvis, and the cervix not taken up. On November 9 the cervix was not flat or open, but the head could be engaged. On November 19, 8 to 11 days after the expected date, examination showed no change. On November 25 vaginal examination showed the cervix to be much shorter and smaller but not open. The patient started in labor spontaneously on November 26, early in the morning, and it was very evident that she was not ready and that labor would be long. She did poorly and labor was terminated the following afternoon, November 27, because meconium began to come away (this was after the membranes had ruptured). The baby weighed 7 lb, 10 oz.

Labor may have been complicated by suspension, but the character of this labor was definitely prognosed by vaginal examination.

Case 7 (No 2681) Para II. This patient was due on dates on April 15-18. Vaginal examination on April 3 showed the cervix to be soft, flat and two-fingers dilated. On April 6 the membranes were ruptured at 9:45 a. m., and the baby was delivered normally at 10:03 a. m. The

cervix at the time of examination was extremely soft and flat and dilated three fingers. The baby weighed 7 lb, 2 oz.

Case 8 (No. 2742.) Para III. This patient was due on dates on December 26-29. On December 15 vaginal examination showed the cervix to be soft and quite flat. On December 21 vaginal examination showed the cervix to be soft, two-fingers dilated, and easily dilatable. The following day the membranes were ruptured at 9 15 a. m. and she delivered herself in 35 minutes of a baby weighing 8 lb.

These two cases are ideal examples of the value of determining the condition of the cervix in cases of elective induction.

The next few cases are interesting from the standpoint of the determination of the end of pregnancy by the changes observed in the cervix rather than by dates.

Case 9 (No. 2061.) This patient was due on dates on May 21-24. She lived in New York and came to Boston the end of April, hoping to have her baby as soon as the baby was ready to come. Vaginal examination on May 23 showed the cervix to be soft, but not in the least bit taken up. Examination on June 1 showed the cervix to be shorter, but still not ready. On June 10 the cervix was soft but not obliterated. On June 18 the cervix was practically flat and just admitted one finger. In spite of her request that labor be started, this patient was told that she was not ready to have her baby, and she did not start in labor spontaneously until June 30, which was five weeks later than the estimated date. The baby was not unduly large, weighing only 7 lb., 10 oz., and the patient had a perfectly normal labor.

Case 10 (No. 2904.) Para I. This patient was due on dates on June 8-11. Vaginal examinations began on May 28, at which time the cervix was not taken up or flat. On June 11, 18 and 25 the cervix was still not flat. On July 2 the cervix had begun to show the changes that one expects to feel toward the end of pregnancy. It was almost

flat and dilated one finger. She started in labor spontaneously on the evening of July 8, and was delivered normally the next morning.

Case 11 (No. 2933.) Para I. This patient expected her baby September 16-19. On September 4 the cervix was not flat, soft or open. On September 14 the cervix was not flat or open. On September 21 the cervix was beginning to take up and just admitted a finger. On October 1 the cervix was almost obliterated, but not flat. On October 7 the cervix was still not entirely obliterated and was not open. On October 14 the cervix was almost flat, admitting a finger. On October 16 the patient started in labor, she had a normal labor which was terminated by forceps. The baby weighed 8 lb, 9 oz.

Case 12 (No. 3035.) This patient was a diabetic whose catamenial history was absolutely unreliable. She was always very irregular, at times going as long as 4 and 5 months without flowing. She did not know that she was pregnant until she was 4½ or 5 months along. She thought that her last period was in January, but she did not know whether she had one in December. No vaginal examinations were made until October 6, at which time it was evident that she was about ready to have her baby. The head was well in the pelvis, and the cervix was very soft and dilated one finger. Three days later the membranes were ruptured at 9 00 a. m., and she delivered herself at 3 00 p. m. of a baby weighing 6 lb, 13 oz.

* * *

In conclusion, it has been shown that the normal cervix at the end of pregnancy is an obliterated, soft, patulous organ, that an appreciation of these changes can be obtained only by routine vaginal examinations in the last few weeks of pregnancy, that the latter is a perfectly safe procedure when properly performed, that the cervix is the only index upon which induction should be based, and that the cervix is the real index of the end of pregnancy.

GOUT

Report of an Unusual Case in a Woman

JAMES A. HALSTED, M.D.*

DEDHAM, MASSACHUSETTS

MEDICAL teaching for a generation has led to the belief that gout is a rare disease, so much so that it is often not considered in the differential diagnosis of acute and chronic arthritis. Recent literature¹⁻³ has done much to change this point of view, and to point out the criteria by which the disease may be recognized before tophi appear. The importance of correct diagnosis is self-evident in that the management and prognosis are so different from the other rheumatic

diseases with which it may be confused. Needless removal of suspected foci of infection, vaccine therapy, and so forth, may be avoided by correct recognition of the disease. To summarize the clinical aspects of gout and to record a case with rare features are the purposes of this article.

CASE REPORT

A woman of 69 was admitted to the Faulkner Hospital on September 9, 1937, she had been suffering from acute polyarticular arthritis for 5 weeks. Five years before admission, having been previously in robust health all her life, she had a sudden attack of acute pain in the big toes

*Physician, Faulkner Hospital; assistant in medicine, Harvard Medical School.

of both feet, which lasted 4 weeks and cleared up completely. Repeated careful questioning failed to reveal a history of any previous joint disturbance. Since then she had had many similar attacks in the big toe, the attacks rarely lasting more than 2 weeks until the present one. Occasionally during the past 2 years she had also had attacks involving the knees and wrists as well as the feet. Four years before admission she was told that she had gout and that the blood uric acid was elevated. Five months previously she had an attack following an emotional shock caused by the death of her sister. Five weeks previous to admission she began to have the present attack, which continued unabated and involved the toes, ankles, wrists and knees, and in addition, for the first time, the right shoulder. With this attack she had had no appetite, was constipated, but had had no nausea or vomiting. She had been able to be up and about with considerable discomfort until a few days previously, since when she had had to remain in bed. She had lost 5 lb during the previous 5 weeks.

The family history was significant in that her father had had gout. He died of pneumonia and kidney trouble at 63. Her mother died at 77, cause unknown.

The patient had rarely taken alcohol. She had always eaten sparingly of meat. She rarely ate liver, sweetbreads or kidneys, but was fond of sardines. She took one cup of coffee daily and no cocoa.

She had always been well. An appendectomy had been performed many years before. She had had migraine during her youth, but this had ceased before the menopause. Eight years before her present attack she had had a retinal hemorrhage in the left eye, which resulted in poor vision in that eye since that time. Eight months previously she had a sudden weakness in her right arm and leg and almost fell. She remained in bed 10 days, but was not paralyzed after she got up. The weakness of the right arm and leg had been very slight, and the degree of hemiplegia was not sufficient to cause any pain in the shoulder.

Physical examination revealed a well-developed woman weighing about 150 lb, lying in bed in considerable discomfort. She was unable to move her legs, wrists or right arm easily, but was able to sit up without pain if assisted. The temperature was 102°F, the pulse 80 and the respirations 20. There were no other abnormal findings except as follows. The blood pressure on admission was 190/104, but after she had been in bed for 2 days it fell to 150/90. The liver was just palpable but not tender. The right knee jerk was consistently a little more active than the left, but the Babinski sign was not present. Examination of the extremities showed marked limitation of motion from pain in the knees, ankles and wrists and the right shoulder. There was moderate swelling of the wrists, especially the right, but no fluid was demonstrated in the knee joints and no swelling or redness of the shoulder was noted. There was redness, swelling and dilatation of the veins around both metatarsophalangeal joints, and a small tender lump at this site on the right. There were no tophi in the ears and no swellings over the olecranon processes.

Urinalyses were negative, except that the specific gravity did not go above 1.014 both in routine examinations and in a concentration test. The red-cell count was 4,700,000, with a hemoglobin of 94 per cent (Sahl). The white-cell count on admission was 8000, with 84 per cent polymorphonuclears and 16 per cent lymphocytes. A blood Hinton test was negative. The uric acid was 50 mg per cent (whole blood) on September 9, 130 (serum blood taken under oil) on September 11, and 8.25 (serum) on

September 15.* The nonprotein nitrogen was 50 mg per cent on September 9 and 44 on September 15. The blood sugar was 108 mg per cent on September 15. The sedimentation rate was 125 mm. per minute on September 30 (normal, 0.08 to 0.35 mm per minute, Rourke-Ernstene method).

The bromsulphalein and galactose tolerance tests for liver function were both within normal limits. An intra-venous phenolsulfonphthalein test done on September 12 revealed dye excretion of only 13 per cent at the end of 15 minutes, with a total of 68 per cent in 2 hours.†

X-ray photographs of the involved joints showed mild hypertrophic changes around the joints, and punched-out areas in the first left metatarsal bone and the first cuneiform bone, of a type characteristic of gout (Fig 1).

Figure 1 X-ray photographs of the left foot, taken August 16 by Dr Charles A Whelan. Note punched-out areas in the head of the first metatarsal and the first cuneiform bone.

The patient was extremely uncomfortable on admission, but was markedly relieved of all her acute pain after administration of colchicine (1/120 gr every 2 hours for four doses on 2 successive days). This amount of the drug produced diarrhea.

The temperature fell to normal on the 3rd hospital day. She was seen in consultation by Dr Charles L. Short, who agreed with the diagnosis of gout. She was discharged September 17, 9 days after admission. At this time the skin around the right great toe began to desquamate. She continued having stiffness and a certain amount of aching off and on for 2 weeks after discharge. The right shoulder remained stiff and painful longer than the other joints. On October 18 she was again given colchicine to the point of diarrhea because of exacerbation of pain in the shoulder, and this relieved the pain promptly and completely. After discharge her appetite and sense of well-being gradually improved, the joint stiffness improved, and she was able to walk almost normally 1 month after admission to the hospital and 8 weeks after the onset of symptoms. Treatment, except for colchicine for the acute attack, consisted of massage and mild physiotherapy.

*The upper limit of normal for uric acid in whole blood is 4.5 and in serum 6.0 mg per cent (Folin 1933 method).

†The lower limit of normal excretion of the dye at the end of 15 minutes in this test is 25 per cent.

after the acute symptoms had subsided, gradual resumption of activity, and a low-purine, high-carbohydrate and low-fat diet with a large fluid intake. She was given 20 gr of aspirin daily for 10 days after discharge, more than that amount having produced tinnitus. On November 17 she was seen at the office and reported having occasional joint ache of mild degree. She was given Tolysin (neocinchophen) at this time, to be taken in 0.5-gm. doses three times a day twice a week for 4 weeks, and reported by telephone on December 22 that she had been very much better when taking this drug. It was not continued after that date. On February 2, 1938, she reported never having felt better in years. She had gained 8 lb.

The diagnosis of gout in this patient, correctly made soon after the onset, is undoubted, since the clinical features were characteristic, namely, she had recurring attacks of acute arthritis with complete remission between attacks, the attacks tending to last longer as time went on, the metatarsophalangeal joint of the great toe was frequently involved, she had an elevated blood uric acid, the x-ray showed a punched-out area characteristic of gout in one metatarsal bone, colchicine gave almost complete and prompt relief of symptoms. Credit should be given to the physician who correctly diagnosed this case soon after the onset four years before, inasmuch as the average duration of time between the first attack and the correct diagnosis was fifteen years in a series of 100 cases studied by Hench.¹

There are three features about this case which are very unusual. First, the patient is a woman. Gout is a disease of men, so much so that it is difficult to defend such a diagnosis in a woman. Most statistics give an incidence of about 98 per cent in men. Secondly, the patient's first attack did not occur until the age of sixty-four. In a series of 116 cases studied by Williamson⁵ only 1 case had the first attack after the age of sixty, the large majority starting between thirty and fifty, an age of incidence which agrees with other reported figures. Thirdly, the shoulder joint was involved. It is very rare for gout to involve the joints of the torso, hips or shoulders, and some clinicians of large experience in gout have never seen involvement of these joints.⁶

In addition, as frequently accompanies gout, she had evidence of kidney disease with delayed phenolsulfonphthalein excretion, slightly elevated blood nonprotein nitrogen and inability to concentrate urine normally, and of arteriosclerosis with a mild hemiplegia.

ETIOLOGY

Little is known of the etiology of gout except that there is a disturbance of uric-acid metabolism. The hyperuricemia and urate deposits, however, are not the cause but simply an index of gout, and

injection of uric acid in a gouty subject will not provoke an attack. The disease is undoubtedly chronic, and the attacks are merely "acute explosions." Although considerable chemical and metabolic information regarding gout has been assembled,⁷ there is actually little more real understanding of the pathologic physiology of the disease than there was fifty years ago.

INCIDENCE

As pointed out above, the usual medical impression regarding gout is that it is a disappearing disease rarely seen nowadays. Because of this attitude, according to Hench,² only 1 out of 4 or 5 cases is correctly diagnosed in its early stages in the absence of tophi and chronic hyperuricemia. On the other hand, the diagnosis may be made too freely so that only 1 of 2 or 3 patients so diagnosed actually has the disease, since many chronic arthritides with transiently elevated blood uric acid, but without the characteristic clinical features of gout, are included. These two attitudes reflect either a lack in general knowledge of the clinical features of gout, or—more important, perhaps—the belief of most physicians that gout is so rare that it should not be seriously considered in the differential diagnosis of arthritis. That gout is not rare is attested by many reports on the disease, and at the Mayo Clinic 5 per cent of the cases seen by arthritic consultants are cases of gout.⁸ The author has seen 1 other case in private practice within six months. Without doubt the incidence of gout will increase with increasing consciousness of its clinical aspects.

CLINICAL FEATURES

Gout is a disease of men, and as a rule begins after thirty-five. A hereditary aspect is undoubtedly a prominent feature of the disease, although not in the cases reported in this country, probably because it has not been looked for carefully enough. It occurs in 60 per cent of the cases reported in England.^{9*} Gout always begins with acute attacks of arthritis, lasting at first only a few days, and occurring perhaps once a year, later coming more often. As the disease progresses the attacks last longer and occur more frequently, and after many years chronic gouty arthritis may develop with little freedom from joint symptoms at any time. The highly distinctive feature of the disease, however, is the *complete* freedom of symptoms between attacks in the early stages. Thus, one reads of a man who once won an Olympic race between attacks of gout.¹¹ The attacks are very sudden and

* Jacobson¹⁰ obtained high serum uric acid levels in 3 non-gouty relatives of 3 gouty patients suggesting an inherited metabolic defect.

acute, although they may be preceded for a few days by gastrointestinal symptoms, as anorexia or indigestion, or by irritability and dizziness. They are said to begin chiefly between 2 and 7 a. m. and they reach their maximum intensity within twenty-four to thirty-six hours. The great toe is involved in not more than 60 per cent of the cases, this is in contrast to an impression that podagra is universally present.² In the other 40 per cent, one or more of the other small joints of the extremities may be involved, the hips, spine and shoulders rarely being involved.

During the attack the joint involved becomes acutely inflamed, bluish red and tense, with dilatation of the vessels around it. The skin is apt to be shiny, with edema and later desquamation and itching. Tenderness of the great toe, so often the site of involvement, is on the mesial aspect of the metatarsophalangeal joint.

As the disease progresses urates are deposited near or in the small joints of the hands and feet, both olecranon bursae and the ear lobes. A gouty abscess occasionally develops near a joint, and if this abscess is incised, a persistent sinus may develop. The x-ray at this stage is apt to show punched-out areas in the subchondral bone, especially the heads of the metatarsals. The x-ray may not, however, be of much assistance in diagnosis inasmuch as changes do not occur until late in the disease. The blood uric acid is not invariably elevated during all stages of gout, according to Hench.² At first the elevation may be transient during an attack (or even absent), with normal levels between attacks. Later the elevation is more persistent, and in chronic gouty arthritis permanent. Jacobson's comprehensive data, on the other hand, indicate that only rarely is a normal serum uric-acid level obtained during any stage when the test is carried out under proper conditions (blood taken under oil).¹⁰

During an acute attack the patient may have moderate fever. The blood examination is not characteristic. The sedimentation rate may be elevated, as in the case reported here. Chronic vascular nephritis is very common in association with gout, as well as renal stones, presumably on account of the difficulty the kidney has in excreting uric acid. This association is so common that any patient with arthritis and renal disease should be suspected of having gout.

Attacks of gout are very likely to be precipitated by various episodes, which may seem so unimportant that the patient is unaware of them, such as trauma, — which may be trivial, — a mild infection, worry or dietary indiscretion. In a gouty patient an operation is very apt to provoke an attack, and acute

arthritis occurring a short time after an operation is nearly always gouty arthritis.² A fishing trip, a long automobile ride or anything which causes an upset in the ordinary routine of life may cause an attack. Treatment for some other disease, such as insulin or Salyrgan, a ketogenic diet, liver therapy, and so forth, may each precipitate attacks of gouty arthritis.

DIFFERENTIAL DIAGNOSIS

Gonorrheal arthritis, rheumatic fever, trauma, acute bursitis, hemophilia, acute rheumatoid arthritis and septic joint are the main conditions in which acute arthritis occurs. The clinical features of all are so different from gout that no difficulty should be experienced in differentiating them, provided gout occupies a prominent place in the mind when one is thinking what a case of acute arthritis may be. If gout is not seen until the stage of chronic gouty arthritis has been reached, the differential diagnosis will lie between rheumatoid and hypertrophic arthritis. The history of onset is the most important differential feature, hypertrophic arthritis being always, and rheumatoid arthritis usually, insidious in onset, whereas chronic gouty arthritis is invariably preceded by acute attacks with complete remission.

TREATMENT

It is not within the scope of this paper to discuss treatment in detail. Furthermore, when one evaluates the discussions in the literature on the therapy of gout, one comes to the conclusion that little of value has been contributed since colchicum was introduced by von Stoerck in 1763. (Actually a plant remedy, hermodactyl, was used in 500 A.D. with great success, this was later discovered to be the same plant as colchicum.¹¹) Theoretically, a purine-free diet should be adhered to, but doubt exists whether such a diet has any effect in reducing attacks.³ Because Lockie and Hubbard¹² were able to provoke attacks with high fat diets, it is doubtless wise to limit fats. It is of interest that, during the War, gout practically disappeared in Germany, owing probably to the small amount of meat available and to widespread malnutrition.¹³ The theoretically ideal gout diet is a purine free, low-fat, high-carbohydrate, liberal protein one. In practice it is probably best to insist on a reasonably simple low-calorie diet, prohibiting high purine foods, with especial emphasis on regularity of meals and routine of life, without excesses of any kind and with a large fluid intake. Dehydration from exercise should be carefully avoided.

Cinchophen, which causes increased excretion of uric acid, produces such serious liver damage in

the rare patient who is sensitive to the drug that many authorities advocate its complete abandonment in the therapy of gout, especially as salicylates are reported to be just as effective in promoting uric-acid excretion.⁸ Other workers, such as Hench,⁹ feel that cinchophen is so valuable in preventing attacks and the sensitive patient so rare that it should be used. If it is to be employed, neocinchophen, which is less toxic, is preferable. A dose of 0.5 gm three times a day two or three times a week for a month, alternating with periods of freedom from the drug, may be effective in preventing attacks.

Colchicine, the action of which is unknown, acts as a specific in the treatment of the acute attack, and is by far the most valuable drug in the management of gout. It should be used in frequent doses, such as 1/120 gr every one or two hours until nausea, vomiting or diarrhea occurs. It is usually not effective unless enough is given to produce gastrointestinal symptoms. When the amount sufficient to produce diarrhea has been determined for the individual patient, somewhat less than this amount may be given at succeeding attacks, in the hope of producing the desired therapeutic effect without diarrhea.³ The patient should be advised to have it on hand at all times.

SUMMARY

A case of gout with three unusual features is presented, and the clinical aspects of the disease are discussed.

The opinion is expressed that, if physicians become aware of gout as a serious possibility in the differential diagnosis of arthritis, the disease will not infrequently be recognized.

CASE RECORDS OF THE FAULKNER HOSPITAL

Antemortem and Postmortem Records as Used in Monthly
Clinicopathological Conferences*Directed by J BEACH HAZARD, MD*

CASE 6377

PRESENTATION OF CASE

A fifty-four-year-old American housewife was admitted because of gradually increasing weakness and the finding of sugar in the urine.

For over a period of several months the patient had been "going down hill." Her appetite had been poor and there had been a very marked loss of strength and, it was believed, weight. She had experienced some pain in the left lower back but there had been no abdominal pain. A rather marked thirst had been noted and one month before admission sugar had been found in the urine. There was no dysuria or polyuria. Just previous to entry there had been some incontinence of urine.

In the past there had been no serious illnesses except diphtheria in childhood. The history in respect to heart, lungs and kidneys was negative. There had been no previous history of diabetes. The patient had had four children, and there had been one or two miscarriages.

Physical examination showed a rather pale woman of middle age. Temperature on admission was 96.0°F, pulse rate, 84, respirations, 24, and blood pressure, 140 systolic, 80 diastolic. Head, ears, eyes, nose and throat were negative. The vessels were moderately sclerotic. The heart was enlarged to the left and presented a rough, apical systolic murmur. There were a few rales at both lung bases. Palpation of the abdomen revealed a large, non-tender mass in the left upper quadrant, which was interpreted as being spleen and also a questionable mass in the midepigastrium. The extremities were negative.

Admission urine showed a specific gravity of 1.008, was clear, straw colored and acid, and showed the slightest possible trace of albumin and a slight trace of sugar. No erythrocytes were present in the sediment but many leukocytes were found. The white-blood count was 17,500 with 81 per cent polymorphonuclears. The red-blood count was 3,700,000 with a hemoglobin of 69 per cent (Sahli). Erythrocytes showed a slight anisocytosis but otherwise appeared normal, as did the platelets. Stool examination was negative. A blood

nonprotein nitrogen done two days after admission was 30 mg per cent. Blood sugar on admission was 283 mg per cent. A blood Hinton test was negative.

During the evening of entry the patient's temperature rose to 102°F and during the first four teen days of her stay continued to fluctuate between 99 and 103°F. While in the hospital she got along very well on from 5 to 10 units of insulin a day. Four days previous to death her blood sugar was 182 mg per cent.

An x-ray examination was made five days after admission. A flat film of the abdomen showed the right kidney outline to be fairly well demarcated and of about normal size and position. A mass was visible in the left flank which was about 12 cm in diameter and lay just above the iliac crest. The kidney outline on the left was not clearly demarcated. An apparently normal spleen shadow was seen. The stomach was in median position and showed normal tone and peristalsis and no irregularity or defect, and no evidence of pressure defect. The duodenum was normal throughout. A barium enema showed a colon which filled easily, the splenic flexure was displaced downward, and with the patient lying on her back, there was a pressure defect at the proximal end of the splenic flexure. With a picture taken face down this defect was relieved. Films of the chest showed a slight elevation of the left diaphragm. There was a slight increase in normal lung markings at the left base, but no evidence of consolidation or metastases. The heart was enlarged to the left, and the aortic knob was prominent. Cystoscopic and pyelographic examinations were done five days after admission. A flat film showed the left catheter to extend only to the superior level of the body of the fifth lumbar vertebra. Following injection, a very low lying kidney with a sharp angulation at the ureteropelvic junction was seen. There was a slight pressure defect involving the superior aspect of the pelvis and the upper calyx. Urine from the left kidney showed numerous red blood cells, numerous leukocytes and frequent epithelial cells, and the specimen from the right kidney contained innumerable erythrocytes and leukocytes and showed numerous epithelial cells. A culture of the left ureter and a specimen of the bladder urine showed *Bacillus coli*.

and *Staphylococcus albus*. A Widal test performed eight days after admission was negative.

Four days before exitus the physical signs in the lungs cleared up. The blood nonprotein nitrogen was 31 mg per cent. At this time the patient's temperature returned to normal and so remained until just before death, when it rose to 102°F. Extreme weakness persisted throughout her stay in the hospital. Death occurred eighteen days after admission, was sudden and unexpected, and was preceded by a convulsion involving chiefly the left side of the face, left leg and left arm.

DIFFERENTIAL DIAGNOSIS

DR. F. WILLIAM MARLOW, JR. I think we can at once rule out uncomplicated diabetes as the entire explanation, since that would be too simple. The incontinence of urine is a symptom which cannot be lightly passed off. Incontinence may mean involvement of the spinal cord, it may be associated simply with weakness of the patient although that is not suggested by the preceding history. As the extremities were negative, one must assume that there was no serious spinal-cord lesion. A blood pressure of 140 systolic, 80 diastolic, in a person who has had progressive weakness, is suggestive to me that she may well have had a higher blood pressure at a previous time. The heart was enlarged to the left, and the aortic knob prominent, these are findings consistent with a hypertensive arteriosclerotic type of heart. There were a few rales at both lung bases. One wonders whether there was dullness or whether the rales were more than the few scattered ones which many elderly people have without any pathological evidence of disease. Palpation of the abdomen revealed a large, non tender mass in the left upper quadrant which was interpreted clinically as being spleen. This is the first mentioned physical sign which could not be associated with her diabetes. The laboratory findings help us to the extent of indicating that there is a chronic process which has reduced the blood count, and this suggests that there is a background of infection contributing to the patient's immediate history.

It is unfortunate that a blood culture was not taken, and I should like to know what the repeat white counts were.

DR. J. BEACH HAZARD. The admission white count was 17,500. Seven days later the count was 17,000, three days later, 10,250, and five days later 13,850.

DR. MARLOW. During the evening of the day of entry the patient's temperature rose to 102°F and during the first fourteen days of her stay continued to fluctuate between 99 and 103°F. Extensive carcinoma occasionally will give a swinging temperature of that extent. I think it very rare, however,

except when the cancer produces marked emaciation and when there is evidence of many metastases throughout the body. So that with the elevated white count one must question very seriously whether an infectious background in this picture is not an important consideration. Typhoid fever was considered, and a negative Widal found. A negative Widal does not necessarily prove anything, although it is contradictory to the idea that this patient had typhoid fever. The possibility of a localized abscess in the abdomen should be considered. One cannot help wondering whether bacterial endocarditis was present, even though the heart is not of the type usually associated with this disease.

Then we come to a consideration of the x-ray findings, which showed a large mass in the left flank. What could it be? An enlarged spleen ordinarily rides in front of the colon, on abdominal palpation. The kidney comes in ordinarily from behind and usually does not displace the colon unless the mass is very large. One thinks of the possibility of a lymphoma in the posterior abdominal cavity. Carcinoma of the head of the pancreas or a cyst of the pancreas are possibilities but one would think that the duodenum should be displaced or show a pressure defect. Films of the chest showed a slight elevation of the left diaphragm. I wonder whether it was fixed. A mass in the abdomen can cause an elevated diaphragm, but if that mass is of an inflammatory nature, one would expect the diaphragm to be fixed as compared with the movement on the right.

Cystoscopic examination done five days after admission showed the kidney to be placed abnormally low on the left side. One recalls that a floating kidney is six times as common on the right as on the left so one would assume that this is not a simple floating kidney and that there must be something pushing the kidney down. Is it a tumor of the kidney itself or is there some other abnormal process behind the kidney, pushing it down? The next statement is that the pelvis and calices themselves were within normal limits. The most common tumor of the kidney is hypernephroma. One characteristic change which hypernephroma causes, in addition to displacement, is a drawing out of the pelvis, not a compression, so that one may assume that this patient did not have a hypernephroma. A pressure defect means that the tumor was pressing on the kidney rather than being in the kidney itself. Urine from both sides was essentially the same, both specimens showing numerous red cells and leukocytes. The numerous red cells on the left following cystoscopy might be purely the result of trauma. Therefore, one cannot pay a great deal of attention to that. However, the presence of epithelial cells and leuko-

cytes is evidence of kidney-parenchyma involvement and I am wondering if there may have been a generalized infection involving the kidney. A culture of the urine from the left ureter and a specimen of bladder urine both showed *Bacillus coli* and *Staphylococcus albus*. One usually does not pay much attention to *Staphylococcus albus*, but I cannot help regarding it with suspicion.

Four days before death, physical signs at the bases of the lungs cleared up. In spite of that, however, I should suspect that we should find some bronchopneumonia as a part of the terminal picture. The final episode with a convulsion evidently indicates a process involving the right hemisphere and presents two main possibilities. The first is a cerebral accident on a vascular basis, though this is unusual in a fifty-four-year-old woman with a normal blood pressure and with no evidence of syphilis. The other possibility is embolus. In a patient who has diabetes and who dies suddenly, one would like to have known the blood carbon-dioxide-combining power and the results of tests for acetone bodies in the urine. These were probably not done since the diabetes was extremely mild. I will say that there was some kind of a lesion in the left upper abdomen, with secondary infection and abscess formation. The terminal cerebral embolus may be secondary to an acute endocarditis, and the pus and red cells in the urine may also be explained on an embolic basis. The possibility of septicemia should not be overlooked.

DR. MAGNUS I. SMEDAL: The left diaphragm is a little bit high, but we called the lung fields and chest normal except for that. The esophagus and stomach are perfectly normal. There is no evidence of an enlarged spleen shadow or of an enlarged pancreas. The splenic flexure is displaced downward. With the patient on her back there is a defect in the splenic flexure, but facing downward this is relieved. The kidney is intrinsically negative. Pressure from hypernephroma causes more deformity, it may elongate the calyx but the common occurrence is to destroy by direct pressure. This kidney looks as if there were some mass pushing it up rather than a mass within the kidney itself. We believed there was a retroperitoneal mass, displacing the kidney and the splenic flexure downward. It is not spleen because there is no defect in the stomach.

DR. EDWARD L. YOUNG, JR.: Could it be a cyst of the tail of the pancreas, the infection of the kidney being the cause of the leukocytosis and temperature and entirely incidental to the mild back pressure in the kidney due to its being pushed down?

CLINICAL DIAGNOSES

Diabetes
Pyelonephritis?
Perinephritic abscess?
Retroperitoneal tumor?
Cerebral embolus

DR. MARLOW'S DIAGNOSES

Diabetes
Cerebral embolus
Abscess formation, left upper abdomen
Acute endocarditis with septicemia?
Embolic nephritis?

ANATOMICAL DIAGNOSES

Perinephritic abscesses, bilateral
Chronic pyelonephritis, bilateral
Cirrhosis of liver, alcoholic type
Ascites, slight

DR. HAZARD: The answer to the whole problem is perirenal abscess. There was a large abscess on the left side, a smaller abscess on the other side and a bilateral suppurative nephritis. The organism recovered from the kidneys and abscesses was *Staphylococcus aureus*. Culture of blood from the heart was negative. Other pathological findings were cirrhosis of the liver of the alcoholic type and a beginning ascites. Those are the main diagnosis and the symptomatology was due to the perinephritic abscesses. Sometimes these can be present without anything in the urine, and in a number of instances the only feature they may show is febrile reaction. This diagnosis is one we are all prone to forget in considering a case that shows fever of unexplained origin.

DR. ROBERT SANDERSON: What was the cause of death in this case?

DR. HAZARD: Due to restrictions the brain was not examined, so that I cannot tell you the cause of her death.

DR. MARLOW: Was the heart of the hypertensive type?

DR. HAZARD: No.

DR. LLOYD T. BROWN: On physical examination, was there any costovertebral tenderness?

DR. HAZARD: Unfortunately the record does not mention that. It is said to be a non-tender mass, but there is no statement as to whether a definite attempt was made to demonstrate costovertebral tenderness.

DR. BROWN: I saw a case similar to this that caused a good deal of discussion. The patient showed a similar fluctuating temperature, and palpation of the costovertebral region revealed a very

tender spot. Often that is the only thing on physical examination that gives much help

DR. JOHN J. SACCO I was wondering if the patient was offered an exploratory operation at any time.

DR. HAZARD No Operation was thought of, but the patient's condition was so very poor that she was not considered a good surgical risk

CASE 6379

PRESENTATION OF CASE

First Admission An eighty-year-old, retired clergyman entered the hospital with the complaint of pain in the back

Until three months before admission, while living in the South, he had been perfectly well but at that time began to feel tired and somewhat depressed. His wife attributed this to the recent death of a sister and a brother. Six weeks before admission he developed a cold which persisted for a month and was accompanied by a low-grade fever. He motored North but was forced to stay in bed for ten days on the way. At this time he had some cramps in his legs. Two weeks before admission he came to Boston and began having persistent pain in the lower lumbar region radiating around the abdomen on both sides. This was relieved by hot applications and aspirin. His bowels, always constipated, became more so. He had had a poor appetite for three months but had no nausea or vomiting, there had been a good deal of gas and some indigestion, which were relieved by having bowel movements, usually obtained by enemas. He had lost about 10 lb in weight.

A sister died six months before admission with what was thought to be a ruptured abdominal aneurysm. One brother died a year previous to entry. He had two sisters living and well.

His past history was negative except for lifelong constipation. He had always been rugged. Seven years before he entered the hospital a diagnosis of hypertrophic arthritis of the spine was made.

Physical examination revealed a rather obese man with good color who did not look very ill but had obviously lost weight. The heart was normal. The blood pressure was 130 systolic, 80 diastolic. The lungs were clear, but there were signs of moderate emphysema. The abdomen was soft with slight tenderness in both lower quadrants. There were no masses or organs palpable and no spasm. The knee jerks were normal, and the extremities negative.

The temperature was 100.6°F., the pulse 80. The respirations were 19.

One urine specimen showed a specific gravity of 1.020, a trace of albumin, no sugar, from 4 to 6

red blood cells per high-power field, rare white blood cells, and no casts. Several white-blood-cell counts ranged from 10,850 to 19,000 with differential counts of polymorphonuclears from 27 to 60 per cent, lymphocytes from 38 to 53 per cent, and monocytes from 7 to 8 per cent. One smear had 3 per cent young polymorphonuclear cells. The red-blood-cell count was 5,000,000 with 98 per cent hemoglobin (Sahli). One stool examination was negative. X-rays showed marked degenerative changes in the spine with a right lumbar scoliosis, marked arteriosclerosis of the iliac and femoral vessels, a negative colon by barium enema, and no abnormal shadows in the flat plate of the abdomen.

He remained in the hospital for four days during which time his temperature rose to about 100.8°F each evening, being normal the following morning. His pulse varied between 70 and 80.

Second Admission (two weeks later) The interval history revealed that the symptoms of backache and constipation with mild abdominal distress and the low-grade fever had continued. The urine on one examination for Bence-Jones protein was positive. Eight days after discharge he had sudden severe pain in the left popliteal space, and a large pulsating swelling appeared in this area. The left leg became swollen and tender, but the foot was normally warm. Neither dorsalis pedis artery was palpable. Three days after this event the patient was admitted to the hospital where the femoral artery was ligated just below the profunda femoris artery. He responded satisfactorily: the pulsation ceased, the leg remained warm, and the swelling gradually subsided. While in the hospital an agglutination test for undulant fever was positive in a serum dilution of 1:640. The blood nonprotein nitrogen was 43 mg per cent, the serum protein 6.5 gm per cent. A test for Bence-Jones protein was repeated and was negative. He remained in the hospital for four days during which time he had an evening rise in temperature to 100°F.

Three days after discharge from the hospital he went to a nearby summer resort by ambulance where he remained three months. After three weeks he was able to walk, but he developed a foot drop. He was given antitubercella serum by his local physician with a resultant severe reaction but after this the fever disappeared and he improved considerably in weight and appetite, and was able to be more active. His digestive symptoms improved. The undulant fever agglutination test was repeated and remained positive in high dilution. Ten days before returning from his summer home his physician felt a very hard, apparently pulsating mass in the right upper quadrant. The day after he returned home he had a severe attack of persistent vomiting which was relieved by morphine. The next day

cytes is evidence of kidney-parenchyma involvement and I am wondering if there may have been a generalized infection involving the kidney. A culture of the urine from the left ureter and a specimen of bladder urine both showed *Bacillus coli* and *Staphylococcus albus*. One usually does not pay much attention to *Staphylococcus albus*, but I cannot help regarding it with suspicion.

Four days before death, physical signs at the bases of the lungs cleared up. In spite of that, however, I should suspect that we should find some bronchopneumonia as a part of the terminal picture. The final episode with a convulsion evidently indicates a process involving the right hemisphere and presents two main possibilities. The first is a cerebral accident on a vascular basis, though this is unusual in a fifty-four-year-old woman with a normal blood pressure and with no evidence of syphilis. The other possibility is embolus. In a patient who has diabetes and who dies suddenly, one would like to have known the blood carbon-dioxide-combining power and the results of tests for acetone bodies in the urine. These were probably not done since the diabetes was extremely mild. I will say that there was some kind of a lesion in the left upper abdomen, with secondary infection and abscess formation. The terminal cerebral embolus may be secondary to an acute endocarditis, and the pus and red cells in the urine may also be explained on an embolic basis. The possibility of septicemia should not be overlooked.

DR. MAGNUS I. SMEDAL: The left diaphragm is a little bit high, but we called the lung fields and chest normal except for that. The esophagus and stomach are perfectly normal. There is no evidence of an enlarged spleen shadow or of an enlarged pancreas. The splenic flexure is displaced downward. With the patient on her back there is a defect in the splenic flexure, but facing downward this is relieved. The kidney is intrinsically negative. Pressure from hypernephroma causes more deformity; it may elongate the calyx but the common occurrence is to destroy by direct pressure. This kidney looks as if there were some mass pushing it up rather than a mass within the kidney itself. We believed there was a retroperitoneal mass, displacing the kidney and the splenic flexure downward. It is not spleen because there is no defect in the stomach.

DR. EDWARD L. YOUNG, JR.: Could it be a cyst of the tail of the pancreas, the infection of the kidney being the cause of the leukocytosis and temperature and entirely incidental to the mild back pressure in the kidney due to its being pushed down?

CLINICAL DIAGNOSES

Diabetes
Pyelonephritis?
Perinephritic abscess?
Retroperitoneal tumor?
Cerebral embolus

DR. MARLOW'S DIAGNOSES

Diabetes
Cerebral embolus
Abscess formation, left upper abdomen
Acute endocarditis with septicemia?
Embolic nephritis?

ANATOMICAL DIAGNOSES

Perinephritic abscesses, bilateral
Chronic pyelonephritis, bilateral
Cirrhosis of liver, alcoholic type
Ascites, slight

DR. HAZARD: The answer to the whole problem is perirenal abscess. There was a large abscess on the left side, a smaller abscess on the other side and a bilateral suppurative nephritis. The organism recovered from the kidneys and abscesses was *Staphylococcus aureus*. Culture of blood from the heart was negative. Other pathological findings were cirrhosis of the liver of the alcoholic type and a beginning ascites. Those are the main diagnoses and the symptomatology was due to the perinephritic abscesses. Sometimes these can be present without anything in the urine, and in a number of instances the only feature they may show is a febrile reaction. This diagnosis is one we are all prone to forget in considering a case that shows a fever of unexplained origin.

DR. ROBERT SANDERSON: What was the cause of death in this case?

DR. HAZARD: Due to restrictions the brain was not examined, so that I cannot tell you the cause of her death.

DR. MARLOW: Was the heart of the hypertensive type?

DR. HAZARD: No.

DR. LLOYD T. BROWN: On physical examination, was there any costovertebral tenderness?

DR. HAZARD: Unfortunately the record does not mention that. It is said to be a non tender mass, but there is no statement as to whether a definite attempt was made to demonstrate costovertebral tenderness.

DR. BROWN: I saw a case similar to this that caused a good deal of discussion. The patient showed a similar fluctuating temperature, and palpation of the costovertebral region revealed a very

DR. MAURICE B. STRAUSS Were blood cultures taken?

DR. J. BEACH HAZARD No

DR. JAMES A. HALSTED I took care of this patient. On his first admission it was thought that the back pain, fever and unusual blood counts were suggestive of metastatic carcinoma of the vertebrae. When the agglutination tests were found to be positive at the second admission it was felt that undulant fever adequately explained all his symptoms, including the back pain, inasmuch as that disease may produce joint pain. Two months later, when the abdominal tumor was discovered, it was concluded that he had two diseases—the tumor, which must have been present for some time before it became palpable, was judged to be responsible for his backache, and the brucella infection for his fever.

DR. EUGENE E. O'NEIL I think it is particularly interesting to have circulation return so quickly after ligation of a main vessel in a man of this age who has, obviously, generalized arteriosclerosis. We have great difficulty, or I think we have great difficulty, in trying to improve collateral blood supply in such a condition, and if this leg had been put in a vasculator or some similar type of apparatus following the operation, we might have falsely ascribed the improvement to the apparatus. One would expect that this patient would go on to death as a result of gangrene of his leg.

CLINICAL DIAGNOSES

Abdominal aneurysm, arteriosclerotic, with rupture
Undulant fever
Popliteal aneurysm, arteriosclerotic
Arteriosclerosis

DR. GARREY'S DIAGNOSES

Abdominal aneurysm, arteriosclerotic, with rupture
Undulant fever
Popliteal aneurysm, arteriosclerotic
Advanced arteriosclerosis

ANATOMICAL DIAGNOSES

Aneurysm of the abdominal aorta, arteriosclerotic, with rupture
Hemoperitoneum
Focal inflammatory lesions of liver (consistent with undulant fever)
Arteriosclerosis, marked
Benign nephrosclerosis
Distention of lacteals of small intestine, secondary to aneurysm in mesentery
Old perisplenitis
Benign hypertrophy of the prostate

PATHOLOGICAL DISCUSSION

DR. HAZARD The mass in the abdomen was a ruptured aneurysm of the abdominal aorta. It is interesting to see how much clot can be present without obstruction of the vessel lumen. The aneurysm perforated anteriorly through the mesentery, into which it had previously ruptured. There was a large amount of arteriosclerosis in the aorta and the iliac arteries. As to the etiology of the aneurysms, I went through all the cases of undulant fever I could find in the literature for the past decade, and in only one instance was there a case that had died from rupture of an artery. That was a case of rupture of a mycotic aneurysm of a cerebral artery. So far we have not been able to demonstrate organisms in the sections of the wall of the aneurysm. We are apparently dealing with a man that had two diseases—a very marked arteriosclerosis, with the unfortunate addition of an aneurysm, and undulant fever. There were large atheromatous abscesses in the intima of both the aorta and the iliac vessels. Examination was limited to the abdomen, and the popliteal artery could not be examined. There was no occlusion of the renal artery. The kidneys showed rather marked benign nephrosclerosis.

DR. HALSTED I should like to add that the family history in this case is exceedingly interesting inasmuch as the patient's sister, whom I saw, undoubtedly died of this same disease, namely ruptured abdominal arteriosclerotic aneurysm.

he experienced a shaking chill with a temperature rise to 102°F, but it dropped to normal the next day. Following this he began to have rather severe and persistent abdominal pain which increased on moving in bed. The mass seemed to be larger and was definitely pulsating. At this time he developed persistent hiccoughs which were temporarily relieved by withdrawal of two quarts of green-stained fluid by stomach tube. A guaiac test on this fluid was negative. Carbon-dioxide inhalations at intervals for a week were necessary to relieve the hiccoughs. His condition became progressively weaker. The blood nonprotein nitrogen was 67 mg per cent, the red-blood-cell count 3,000,000, and the hemoglobin 60 per cent (Sahli). The urine contained many granular casts. On the twentieth day after his return, two intravenous injections of 1000 cc. of 10 per cent glucose resulted in marked improvement. The urinary output increased, and the urine contained neither casts nor leukocytes. His blood pressure was 120 systolic, 80 diastolic. Two days after this, the patient's temperature rose to 103°F. The lungs were clear, there was no evidence of phlebitis and no change in the abdominal mass. The fever persisted, with an afternoon rise to 103°F.

At noon, twenty-five days after returning from his summer home and eight months after the onset of his illness, he had a sudden sharp pain in his abdomen and died within five minutes.

DIFFERENTIAL DIAGNOSIS

DR. WALTER E. GARREY: On the first entry to the hospital, we have an elderly man who has been sick for three months with recurrent fever, back pain and cramps in his legs. On the second entry there is a story of very sudden severe pain in the left popliteal space, a large, supposedly pulsating, swelling in this region, and a swollen tender left leg with a foot that was normally warm. Neither dorsalis pedis artery was palpable. The left femoral artery was ligated during the second admission, and following that the pulsation ceased, the leg remained warm, the swelling gradually subsided, and after three weeks he was able to walk although a foot drop developed. While he was in the hospital an agglutination test for undulant fever was done and was positive in a serum dilution of 1:640.

As an explanation of the fever, there seems to be sufficient evidence to make a diagnosis of undulant fever. He was in the South where the pasteurization of milk is not a legal requirement, and he ran a course that is compatible with undulant fever. The agglutination test is quite significant because the dilution of 1:640 is a very high titer and he had not received antibrucella vaccine prior to this test. It might have been the result of an old infection

with undulant fever, but his past history is supposed to be negative for any such illness. So, I think we may say that it was active undulant fever. The agglutination test for brucellosis was repeated later and was again positive in high dilution.

It is fairly definite that he developed a popliteal aneurysm between the first and second admissions, that this aneurysm developed suddenly and extensively enough to embarrass his venous return and to press on his peroneal nerve, and that because it was felt that there was an emergency,—a threatening of the foot because of venous congestion and pressure on the nerves in the popliteal space,—a ligation was done, which was apparently successful. This observation of the pulsating tumor appears to be correct, and there is nothing else to be considered.

I suppose there was some conjecture as to how well an elderly person with advanced arteriosclerosis would stand ligation of the femoral artery and whether he would develop any gangrene in the foot. I imagine that preparations had been made to use the vasculator, if necessary. Probably because this was a sudden emergency, no studies were undertaken to try to prove that there was adequate collateral circulation.

The second pulsating mass that developed in the abdomen after he had left the hospital for the second time is probably another aneurysm, and his death was probably due to its rupture. There seems to be an element of renal failure, which contributed to the final picture.

Now it is interesting from the anatomical point of view to speculate as to what the origin of these aneurysms might be. I think that with his advanced arteriosclerosis there is reason to believe that these aneurysms were on an arteriosclerotic basis. A popliteal aneurysm with this etiology and of a size to cause so many symptoms is a rather rare occurrence. I can find no record of an arteriosclerotic popliteal aneurysm in all the cases at the Massachusetts General Hospital, but I think, nonetheless, that this is such a case.

I make my diagnoses: undulant fever, advanced arteriosclerosis, popliteal aneurysm, arteriosclerotic, abdominal aneurysm, arteriosclerotic, with rupture.

DR. EDWARD L. YOUNG, JR.: Might not the nitrogen retention be due to involvement of the orifices of the renal arteries by the aneurysm?

DR. GARREY: I suppose that is possible.

DR. CHANNING FROTHINGHAM: Here is a man that is running a fever and has some damage to his blood vessels. Might it not be called a mycotic aneurysm?

DR. YOUNG: Such lesions are very acute, and they perforate quickly.

DR. GARREY: I do not believe that brucella infection ever causes such vessel lesions.

The other cardinal signs of aneurysm, such as tracheal tug and visible expansile pulsation, are not given and presumably were not present. I should like to ask for advice about the significance of the diastolic thrill. In my experience diastolic thrills are extremely uncommon and certainly would not be expected in aneurysm. A diastolic thrill might occur with rupture of the aortic valve. It is reported that a diastolic thrill can be felt occasionally in aortic regurgitation. I know no other cause for diastolic thrill, and it does not help me to make a diagnosis for or against aneurysm. We have no note as to inequality of pulse or blood pressure, which might tell for or against aneurysm, but nevertheless we have known syphilitic aortic disease and pain between the scapulae. It is a constant pain with occasional twinges, which is characteristic of aneurysm, and I shall make that diagnosis although one great argument against it is the fact that she had an x-ray before coming to the hospital which showed only "enlargement of the heart." If she had had a large enough aneurysm to cause her symptoms she should have had a definite shadow by x-ray.

I believe that she has syphilitic aortic disease with aneurysm, aortic regurgitation, a large heart, and probably syphilis of the central nervous system.

DR. TRACY B. MALLORY: We never saw the film that was taken outside. We have a postmortem film, however.

DR. AUBREY O. HAMPTON: These films were taken at six feet with the cadaver upright, and you can see a dilated arch of the aorta with displacement of the trachea toward the right. We have not been able to rely on the size or shape of the heart post mortem. It changes markedly, but it appears enlarged. The lung fields are normal. There is definite dilatation of the arch of the aorta.

DR. HOWARD B. SPRAGUE: I saw this patient in my office a few days before she was admitted, and one interesting thing about the case is the light it casts upon the type of therapy that such a patient may get when treated by irregular practitioners. She had been treated for neuritis in the back for some time by an osteopathist and, I believe, a chiropractor. Not until increasing dyspnea crippled her did she see a physician, who found something wrong with the heart. I think Dr. Fremont-Smith would have been even more ready to make a diagnosis of aneurysm if he had seen the patient, because she presented the picture of superior mediastinal obstruction of moderate degree with venous engorgement and cyanosis of the face and upper part of the body.

There was a combination of cardiac failure and respiratory failure, and fluoroscopy in my office showed a diffuse dilatation of the aorta.

DR. RICHARD C. CABOT: Did you feel the diastolic thrill?

DR. SPRAGUE: I was surprised to read that I cannot recall that I made the observation.

DR. AUSTIN W. CHEEVER: I saw this patient in consultation the day before she died. I felt there was little doubt of the diagnosis and the question came up as to the therapy. It was perfectly futile to give specific therapy in the condition she was in but in case she improved, if I remember correctly, I suggested that she might be given a little bismuth but certainly not iodides or arsphenamine.

CLINICAL DIAGNOSES

Syphilitic heart disease with aortic regurgitation and aortic aneurysm

DR. FREMONT-SMITH'S DIAGNOSES

Syphilitic heart disease
Aneurysm of aorta, syphilitic
Aortic regurgitation
Hypertrophy of heart
Central-nervous-system syphilis?

ANATOMICAL DIAGNOSES

Syphilitic aortitis
Aneurysms of aorta, diffuse and saccular
Aortic insufficiency
Hypertrophy of the heart
Atherosclerosis of aorta

PATHOLOGICAL DISCUSSION

DR. MALLORY: The postmortem on this patient showed a marked syphilitic aortitis with two aneurysms: a diffuse saccular dilatation of the entire ascending aorta, separated by a normal segment in the region of the arch from a saccular aneurysm which projected back against the vertebral column in the first part of the descending aorta. The second aneurysm arose beyond the mouth of the subclavian artery so I do not believe there would have been a difference in pressure in the two arms. The first of the aneurysms, the one that involved the ascending aorta, extended down as far as the aortic valve cusps, and they were slightly separated from each other, although not very markedly involved. The coronary orifices were perfectly patent. The coronaries in syphilitic heart disease are seldom narrowed except at their mouths unless there is marked coincident arteriosclerosis. The myocardium so far as we could make out grossly and microscopically was normal.

DR. CABOT: Could x-ray have shown the second aneurysm if looked at from the side position?

DR. HAMPTON: This is a lateral plate taken post mortem. It does not show it.

DR. PAUL D. WHITE: If a diastolic thrill was felt in this case it seems as though it was probably

CASE 24171

PRESENTATION OF CASE

A fifty-year-old native-born secretary entered the hospital with the complaint of dyspnea and palpitation of six months' duration.

She was feeling very well until about six months before entry, when she first noticed shortness of breath and palpitation on climbing stairs and when lying flat in bed. However, if she lay on her right side she had very little distress. These symptoms became progressively worse, and two months before entry she began to have a constant, dull ache beneath the shoulder blades which radiated around to the anterior chest and was accompanied by occasional sharp twinges of pain lasting only a moment. About six weeks before entry she began to have a dry, hacking, nonproductive cough which persisted up to the time of entry. She continued her activities up until two days before entry in spite of much distress. Finally she was unable to carry on her work, becoming greatly fatigued on the slightest effort. She slept badly although she never had any definite paroxysmal nocturnal dyspnea. She had never noticed throbbing of her neck vessels, or any other significant symptoms. X-rays taken about a week before entry were said to show an enlarged heart.

She had been married for five or six years about twenty-five years before entry. Her husband had been having treatments of some kind over a long period of time. The marriage was terminated by divorce. She denied ever having had rheumatic fever or any other diseases of importance. She had had no children or miscarriages.

Physical examination revealed an obese, dyspneic woman in obvious distress and complaining of interscapular aching pain. The right pupil was round, of moderate size, and reacted sluggishly to light. The left pupil was round, somewhat contracted, and did not react to light. The heart was grossly enlarged to the right and left, and there was an increase in the width of aortic dullness. A low-pitched diastolic murmur could be heard over the aortic area and a systolic murmur could be heard over the second left interspace. A diastolic thrill was felt over the base of the heart. The blood pressure was 175 systolic, 35 diastolic, there was a collapsing Corrigan pulse, and a pistol-shot sound

could be heard over the femoral vessels. The lungs and abdomen were negative.

The temperature was 98.6°F, the pulse 120. The respirations were 33.

The urine had a specific gravity of 1.020 and contained a slight trace of albumin. The blood showed a red-cell count of 4,670,000 with 80 per cent hemoglobin, and a white-cell count of 12,600 with 87 per cent polymorphonuclears. A Hinton test was positive.

An electrocardiogram showed moderate left axis deviation.

During the first three days in the hospital her condition became progressively worse. She gradually became extremely cyanotic with wheezy respirations and coarse rales in her chest. She refused to tolerate an oxygen tent and finally lapsed into unconsciousness and died on the morning of the fourth day.

DIFFERENTIAL DIAGNOSIS

DR. MAURICE FREMONT-SMITH. A fifty-year-old woman has her first attack of progressive cardiac insufficiency. She has an aortic lesion only. There is no history of rheumatic fever. The Hinton test is positive. A diagnosis of syphilitic cardiovascular disease is inescapable. The problem is what type of syphilitic cardiovascular disease it is. Syphilis of the cardiovascular system starts always in the aorta, attacking the media, and causing a gradual dilatation of the aorta, often symptomless, until either aneurysm or involvement of the aortic valves with failure or narrowing of the entrances of the coronaries develops. I do not know whether the rapid progression that is typical of the course of syphilitic heart failure is always due to involvement of the coronary vessels. In any case it is typical of the syphilitic heart that, when decompensation appears, it goes rapidly forward.

The question of aneurysm comes up, chiefly because of the cardinal symptom of aneurysm, persisting pain in the thorax. I believe that aneurysm occurs in about one third of the cases of syphilitic cardiovascular disease. We are not aided very much in the diagnosis of aneurysm by the physical examination. The fact that the pupils are unequal is not much help because the examination is not satisfactory. The record states: "The right pupil was round, of moderate size, and reacted sluggishly to light. The left pupil was round, somewhat contracted, and did not react to light." That leads us to wonder which of these pupils was the more normal. The fact that a pupil does not react to light may mean a blind eye or an old iritis. It is not an Argyll-Robertson pupil. We want to know whether it reacts to accommodation. A dilated pupil on one side may indicate sympathetic stimulation from pressure.

function gave 0 per cent retained. The Graham test was positive, and a gastrointestinal x-ray series was negative except for probable marked liver enlargement. She finally entered this hospital almost in extremis.

Physical examination revealed a very pale, undernourished, obviously very ill woman with definite jaundice of the skin and sclerae. There were diminished breath sounds and slight dullness at both bases. The heart and lungs were otherwise negative, and the blood pressure was 115 systolic, 70 diastolic. Several enlarged lymph nodes were palpable just above the left clavicle. The abdomen was very much distended with fluid through which no masses could be palpated except the liver edge which extended four fingerbreadths below the costal margin. There was no costovertebral tenderness or spasm. There was definite distention of the superficial vessels on the chest and abdomen, and there was pitting edema of the feet and ankles.

The temperature was 98.6°F., the pulse 105. The respirations were 22.

The urine had a specific gravity of 1.032, and contained albumin, 2+ bile and occasional red cells in the sediment. The blood was essentially the same as it was a month before entry. The stools were guaiac negative on two occasions. The fasting blood sugar was 103 mg., the nonprotein nitrogen 30 mg. and the protein 5.5 gm. per cent. The chlorides were equivalent to 99 cc. of N/10 sodium chloride.

In the hospital she ran a steadily downhill course with progressive cachexia, weight loss, jaundice, ascites, edema and occasional nausea and vomiting. She died on the nineteenth day.

DIFFERENTIAL DIAGNOSIS

DR. GRANTLEY W. TAYLOR. Here is a patient who had obviously a variety of conditions the first one of which came on seven years before her final admission and was characterized by right lower-quadrant pain, coming in attacks severe enough to require morphine, and associated with blood in the urine. Whether it was gross or microscopic blood is not stated, but on several subsequent occasions, in fact on all occasions when the urine was examined, blood cells were present. In spite of the negative intravenous pyelogram we have to conclude that she had some constant source of bleeding in the genitourinary tract, and it seems to me that they were perhaps negligent in not studying it a little more intensively. I suppose stone would be the best explanation of the picture, but it is rather hard to explain why a stone or stones were not seen in the x-ray examination. Certainly I cannot make out that this urinary situa-

tion played any conspicuous part in the subsequent development of the case.

Another point that comes up in the past history, with no further reference to the present illness, is her sensitivity to food—an allergic reaction, presumably. The trip to South America raises the question of possible bizarre parasitic diseases, but I do not believe there is anything in the subsequent history to justify bringing that into the picture.

The other conspicuous finding was the positive Graham test. No mention is made of stones. Presumably there was no filling of the gall bladder, and the test was interpreted as indicating a diseased gall bladder. Then she went along with continuing attacks of pain in the abdomen, and on going elsewhere,—although our pelvic examination was negative,—she was found to have salpingitis, ovarian cyst and endometrial implants, from which I infer she had chocolate cysts or something of that sort, and a calcified mesenteric node was removed without any effect on her symptomatology. The uterus was left behind and presumably, therefore, appeared normal, and since it does not enter into the picture later and since there is no history of bleeding or other abnormal behavior, I think we can rule out the pelvic organs as contributing to the final picture. The operator found matted coils of small intestine which were the result of her appendix operation many years before. Presumably the appendix had been removed, or she would have heard from it afterward.

Beginning about a year before her final entry to the hospital she developed a new train of symptoms characterized by loss of weight, fatigue, a continuous right-sided abdominal pain, nausea and vomiting, and enlargement of the abdomen, on examination she showed a beginning secondary anemia and still had a positive Graham test. In the Out Patient Department and in the hospital her stools were consistently negative for blood. The conspicuous findings on physical examination were jaundice, ascites, large nodes palpable above the clavicle, distention of the superficial veins and pitting edema of the extremities, with a negative cardiac examination. We cannot escape the fact that there was something very wrong with her liver. It seems to me that one may say that this was secondary to the diseased gall bladder, as indicated by the positive Graham test. One can certainly consider the possibility that she developed a biliary cirrhosis, although we ought to have more in the way of jaundice in the past history, if that were to be very seriously considered.

associated with an aortic diastolic murmur rather than aneurysm. If a thrill is felt over an aneurysm it would be systolic as well as diastolic.

DR MALLORY: There seemed to be nothing unusual about this case as compared with many similar cases which would have led to a diastolic thrill in this instance.

A PHYSICIAN: Was there erosion of the vertebrae?

DR MALLORY: No, not to any significant extent.

A PHYSICIAN: Was there tracheal obstruction?

DR MALLORY: We could not make it out post mortem. The symptoms suggest that there had been some. The lungs were equally aerated on both sides.

CASE 24172

PRESENTATION OF CASE

A forty-six-year-old, white, American housewife was studied in the Diagnostic Clinic for attacks of abdominal pain and nausea of five years' duration.

About five years before entry she had an initial attack of severe right lower-quadrant pain which radiated toward the vagina. The pain required morphine for relief and disappeared spontaneously. Her physician found blood in her urine at that time, but an x-ray was reported to be negative. During the next five years she had a series of similar attacks which gradually became more frequent and more severe. Her last attack occurred ten days before entry and was accompanied by nausea. The pain was spasmodic in character and lasted about six hours with each attack. She found that enemas and the application of heat to her abdomen gave some relief. She had no dysuria or other urinary symptoms and no jaundice.

Twenty-three years before entry she had had a ruptured appendix which had been treated surgically with complete recovery. She said that all her life she had been mildly sensitive to certain foods, such as eggs, which caused nausea and vomiting. For nine years during her married life she had traveled all over South America with her husband, who was an electrical engineer. She returned to this country four years before entry. Her past history and family history were otherwise negative. During the three years before entry she had gained 30 lb in weight.

Physical examination revealed a well-developed and nourished woman in no apparent discomfort. The heart and lungs were negative, and the blood pressure was 120 systolic, 80 diastolic. There was deep tenderness in the right upper and lower quadrants, without spasm. No masses were made out.

No femoral or inguinal hernia could be detected, and pelvic examination was negative.

The temperature was 98.4°F, the pulse 98.

The urine had a specific gravity of 1.012 and contained occasional red cells and white cells. The blood showed a white-cell count of 8600 and a hemoglobin of 85 per cent. The blood Hinton test was negative. An intravenous pyelogram showed normal kidney outlines. The dye appeared promptly on both sides and demonstrated normal urinary passages. There were no shadows suggesting stone in the region of the gall bladder, kidneys, ureters or urinary bladder. There was a large area of calcification overlying the fifth lumbar vertebra which had the appearance of a calcified node. A gastrointestinal x-ray series showed no evidence of organic disease in the esophagus, stomach or duodenum, but a Graham test of the gall bladder was positive.

No definite diagnosis was made in the Diagnostic Clinic, and for the next six months she continued to have attacks of pain which became almost continuous. At the end of that time, eighteen months before entry to this hospital, her fallopian tubes and ovaries and a mesenteric lymph node were removed at an outside hospital. The pathological report on these specimens was chronic salpingitis, simple cysts of the ovaries, endometrial implant of the ovary, and calcified mesenteric lymph node. The operator could find no gross lesion in the liver and gall bladder region, but there was marked matting of the lower loops of the intestine. Routine laboratory tests done at that time were negative. She had a normal convalescence followed by severe menopausal symptoms, which were treated with Theelin without much relief. In spite of the operation her symptoms continued, and about a year before entry she began to notice loss of weight and easy fatigue. The right-sided abdominal pain was almost continuous, and she also had severe low backache. She had frequent nausea and vomiting and noticed gradual enlargement of the abdomen. Her loss of strength and weight were progressive during the following twelve months. About a month before entry her blood showed a red-cell count of 3,250,000 with 69 per cent hemoglobin, and a white-cell count of 6800 with 73 per cent polymorphonuclears. A catheter urine specimen showed a specific gravity of 1.015 and contained a slight trace of albumin and numerous red cells in the sediment. A phenol sulfonphthalein test of renal function gave 5 per cent excretion in fifteen minutes, 15 per cent in thirty minutes, 40 per cent in one hour, and 55 per cent in two hours. Four stools were negative for blood, amebae or other parasites. The icteric index was 4, and a bromsulphalein test of liver

function gave 0 per cent retained. The Graham test was positive, and a gastrointestinal x-ray series was negative except for probable marked liver enlargement. She finally entered this hospital almost in extremis.

Physical examination revealed a very pale, undernourished, obviously very ill woman with definite jaundice of the skin and sclerae. There were diminished breath sounds and slight dullness at both bases. The heart and lungs were otherwise negative, and the blood pressure was 115 systolic, 70 diastolic. Several enlarged lymph nodes were palpable just above the left clavicle. The abdomen was very much distended with fluid through which no masses could be palpated except the liver edge which extended four fingerbreadths below the costal margin. There was no costovertebral tenderness or spasm. There was definite distention of the superficial vessels on the chest and abdomen, and there was pitting edema of the feet and ankles.

The temperature was 98.6°F, the pulse 105. The respirations were 22.

The urine had a specific gravity of 1.032, and contained albumin, 2+ bile and occasional red cells in the sediment. The blood was essentially the same as it was a month before entry. The stools were guaiac negative on two occasions. The fasting blood sugar was 103 mg, the nonprotein nitrogen 30 mg and the protein 5.5 gm per cent. The chlorides were equivalent to 99 cc of N/10 sodium chloride.

In the hospital she ran a steadily downhill course with progressive cachexia, weight loss, jaundice, ascites, edema and occasional nausea and vomiting. She died on the nineteenth day.

DIFFERENTIAL DIAGNOSIS

DR. GRANTLEY W. TAYLOR. Here is a patient who had obviously a variety of conditions, the first one of which came on seven years before her final admission and was characterized by right lower-quadrant pain, coming in attacks severe enough to require morphine, and associated with blood in the urine. Whether it was gross or microscopic blood is not stated, but on several subsequent occasions, in fact on all occasions when the urine was examined, blood cells were present. In spite of the negative intravenous pyelogram we have to conclude that she had some constant source of bleeding in the genitourinary tract, and it seems to me that they were perhaps negligent in not studying it a little more intensively. I suppose a stone would be the best explanation of the picture, but it is rather hard to explain why a stone or stones were not seen in the x-ray examination. Certainly I cannot make out that this urinary situa-

tion played any conspicuous part in the subsequent development of the case.

Another point that comes up in the past history, with no further reference to the present illness, is her sensitivity to food—an allergic reaction, presumably. The trip to South America raises the question of possible bizarre parasitic diseases, but I do not believe there is anything in the subsequent history to justify bringing that into the picture.

The other conspicuous finding was the positive Graham test. No mention is made of stones. Presumably there was no filling of the gall bladder, and the test was interpreted as indicating a diseased gall bladder. Then she went along with continuing attacks of pain in the abdomen, and on going elsewhere,—although our pelvic examination was negative,—she was found to have salpingitis, ovarian cyst and endometrial implants, from which I infer she had chocolate cysts or something of that sort, and a calcified mesenteric node was removed without any effect on her symptomatology. The uterus was left behind and presumably, therefore, appeared normal, and since it does not enter into the picture later and since there is no history of bleeding or other abnormal behavior, I think we can rule out the pelvic organs as contributing to the final picture. The operator found matted coils of small intestine which were the result of her appendix operation many years before. Presumably the appendix had been removed, or she would have heard from it afterward.

Beginning about a year before her final entry to the hospital she developed a new train of symptoms characterized by loss of weight, fatigue, a continuous right-sided abdominal pain, nausea and vomiting, and enlargement of the abdomen, on examination she showed a beginning secondary anemia and still had a positive Graham test. In the Out Patient Department and in the hospital her stools were consistently negative for blood. The conspicuous findings on physical examination were jaundice, ascites, large nodes palpable above the clavicle, distention of the superficial veins and pitting edema of the extremities, with a negative cardiac examination. We cannot escape the fact that there was something very wrong with her liver. It seems to me that one may say that this was secondary to the diseased gall bladder, as indicated by the positive Graham test. One can certainly consider the possibility that she developed a biliary cirrhosis, although we ought to have more in the way of jaundice in the past history, if that were to be very seriously considered.

The several enlarged lymph nodes above the left clavicle give the show away to the extent that if they were not due to metastatic carcinoma I doubt whether they would have been noted. Enlarged nodes above the clavicle are late metastatic findings from almost any kind of intra-abdominal cancer. Therefore, we shall narrow this field for the sake of discussion to intra-abdominal cancer and we must grope around to find where it was primary. We consider again that she had a negative upper-intestinal x-ray examination and we recall that she had negative stool examinations for blood, and while all these things are not conclusive, they tend to rule out the gastrointestinal tract as the source. We have already covered the reasons for likewise ruling out the genital tract.

We are then left with certain other areas, notably the biliary tree, the pancreas, and so forth. It might be asked why the long-standing hematuria may not be due to some malignant tumor in the kidney. It seems to me it would be rather hard to account for the enlarged liver, the ascites, the jaundice and the nodes above the clavicle on the basis of a primary process involving the kidney. One thing that I deplore the lack of in the record is the fact that the stools were reported as negative for guaiac but no mention is made whether she had bile in the stools. That might be evidence which would be of use. To say that she had carcinoma involving the pancreas with subsequent jaundice and metastases above the clavicle would very adequately explain the entire picture, and I should incline to make that diagnosis. I can think of nothing else that would be a very satisfactory explanation of the whole picture.

DR. TRACY B. MALLORY: The fact that this woman had metastatic carcinoma was fairly obvious, and on the wards they made that diagnosis but did not attempt to name the primary source, other than to suggest that it might be a pelvic organ. Dr. Taylor has given us one possibility. Are there any other suggestions?

DR. RICHARD CHUTE: It seems to me that the red cells constantly appearing in the urine may be of considerable significance and would point in favor of epidermoid carcinoma of the bladder with metastases.

CLINICAL DIAGNOSES

Metastatic carcinoma of liver (Biopsy by peritoneoscopy)
Cancer in the pelvis?

DR. TAYLOR'S DIAGNOSIS

Carcinoma of the pancreas with metastases to the liver and supraclavicular lymph nodes.

ANATOMICAL DIAGNOSES

Renal-cell adenocarcinoma of left kidney with metastases
Tumor thrombosis of renal vein and vena cava
Cholelithiasis
Cholecystitis, chronic.
Ascites
Edema of legs, genitalia and sacral region.
Icterus
Operative wound appendectomy, bilateral salpingo-oophorectomy

DR. MALLORY: There is one point in the history that was not particularly stressed, but it seems to me that it is the most important lead toward the correct diagnosis. That was the presence of prominent superficial veins over the abdomen and lower part of the thorax, which, in addition to the edema of the extremities, should bring up the possibility of thrombosis of the vena cava. That is what we found. The vena cava was completely occluded from the bifurcations of the iliacs up to the point of its entry into the heart, and it was occluded by tumor tissue. The only tumor that, with any regularity and frequency, does this is hypernephroma, and such a tumor was found in the left kidney which was enlarged to a weight of 700 gm. There were extensive metastases to the liver and lymph nodes elsewhere.

A PHYSICIAN: How do you explain the ascites?

DR. MALLORY: By the thrombosis of the vena cava.

A PHYSICIAN: Did the gall bladder show anything?

DR. MALLORY: The gall bladder did contain a few small stones and a great deal of thick bile, so that the positive Graham test was undoubtedly correct.

THE DRIVE AGAINST CANCER

This month has been set apart by presidential proclamation for a concerted drive against cancer. A mass attack on this disease is essential. Its ravages cannot be prevented by the physician alone or by the patient alone. The early recognition of this important fact, particularly by the late Dr. Robert B. Greenough, has done much for the 400,000 sufferers from cancer now in this country and has saved many from disability and death.

It is unnecessary to call attention to the importance of the cancer problem. There is, however, need to emphasize what has been accomplished and what yet remains to be accomplished in the control of this menace. It is well to realize what advances have been made through the co-operative effort of the medical profession, public-health authorities, and intelligent and enthusi-

astic groups of laymen. In Massachusetts we have four special hospitals for cancer and over twenty cancer clinics. We have alert and interested groups of laymen representing large numbers of organizations co-operating with the Massachusetts Medical Society and the Massachusetts Department of Public Health and looking toward even more adequate cancer control. The widespread effort of the American Society for the Control of Cancer through the past years and its recent special emphasis on the education of women with regard to the dangers of cancer through the Women's Field Army constitute real contributions to the cancer-control program.

It is as important in the education of lay groups to teach them that cancer is curable as it is to teach them other essential facts. To give added emphasis to this important educational aspect, each of the cancer clinics throughout the State is giving this month a session largely devoted to cured cases of this disease—the most concrete evidence of the practical accomplishments of the clinics that we can hope to have.

The death rate in Massachusetts from cancer for women between twenty and sixty years of age has dropped from 119 per 100,000 in 1927 to 112 in 1937. Twenty-four per cent of the patients with cancer are alive ten years after attending the cancer clinics. Last year eighty-six per cent of the patients attending clinics were referred by physicians, and one thousand three hundred and eighty-four physicians attended the sixty-nine teaching clinics.

The Massachusetts Medical Society and the Department of Public Health may well be proud of this record of accomplishment through cordial co-operative effort, and look forward to even more progress in the years to come.

In this number of the *Journal* is an article by Dr. Herbert L. Lombard, covering one of the most fundamental, most controversial and most far-reaching aspects of the whole cancer problem—the role of heredity in relation to the occurrence of the disease in human beings. Dr. Lombard's study of the population of one of our smaller cities has been most careful and most complete. The

The several enlarged lymph nodes above the left clavicle give the show away to the extent that if they were not due to metastatic carcinoma I doubt whether they would have been noted. Enlarged nodes above the clavicle are late metastatic findings from almost any kind of intra-abdominal cancer. Therefore, we shall narrow this field for the sake of discussion to intra-abdominal cancer and we must grope around to find where it was primary. We consider again that she had a negative upper-intestinal x-ray examination and we recall that she had negative stool examinations for blood, and while all these things are not conclusive, they tend to rule out the gastrointestinal tract as the source. We have already covered the reasons for likewise ruling out the genital tract.

We are then left with certain other areas, notably the biliary tree, the pancreas, and so forth. It might be asked why the long-standing hematuria may not be due to some malignant tumor in the kidney. It seems to me it would be rather hard to account for the enlarged liver, the ascites, the jaundice and the nodes above the clavicle on the basis of a primary process involving the kidney. One thing that I deplore the lack of in the record is the fact that the stools were reported as negative for guaiac but no mention is made whether she had bile in the stools. That might be evidence which would be of use. To say that she had carcinoma involving the pancreas with subsequent jaundice and metastases above the clavicle would very adequately explain the entire picture, and I should incline to make that diagnosis. I can think of nothing else that would be a very satisfactory explanation of the whole picture.

DR. TRACY B. MALLORY: The fact that this woman had metastatic carcinoma was fairly obvious, and on the wards they made that diagnosis but did not attempt to name the primary source, other than to suggest that it might be a pelvic organ. Dr. Taylor has given us one possibility. Are there any other suggestions?

DR. RICHARD CHUTE: It seems to me that the red cells constantly appearing in the urine may be of considerable significance and would point in favor of epidermoid carcinoma of the bladder with metastases.

CLINICAL DIAGNOSES

Metastatic carcinoma of liver (Biopsy by peritoneoscopy)
Cancer in the pelvis?

DR. TAYLOR'S DIAGNOSIS

Carcinoma of the pancreas with metastases to the liver and supraclavicular lymph nodes

ANATOMICAL DIAGNOSES

Renal-cell adenocarcinoma of left kidney with metastases
Tumor thrombosis of renal vein and vena cava
Cholelithiasis
Cholecystitis, chronic
Ascites
Edema of legs, genitalia and sacral region
Icterus
Operative wound: appendectomy, bilateral salpingo-oophorectomy

DR. MALLORY: There is one point in the history that was not particularly stressed, but it seems to me that it is the most important lead toward the correct diagnosis. That was the presence of prominent superficial veins over the abdomen and lower part of the thorax, which, in addition to the edema of the extremities, should bring up the possibility of thrombosis of the vena cava. That is what we found. The vena cava was completely occluded from the bifurcations of the iliacs up to the point of its entry into the heart, and it was occluded by tumor tissue. The only tumor that, with any regularity and frequency, does this is hypernephroma, and such a tumor was found in the left kidney which was enlarged to a weight of 700 gm. There were extensive metastases to the liver and lymph nodes elsewhere.

A PHYSICIAN: How do you explain the ascites?

DR. MALLORY: By the thrombosis of the vena cava.

A PHYSICIAN: Did the gall bladder show anything?

DR. MALLORY: The gall bladder did contain a few small stones and a great deal of thick bile, so that the positive Graham test was undoubtedly correct.

THE DRIVE AGAINST CANCER

This month has been set apart by presidential proclamation for a concerted drive against cancer. A mass attack on this disease is essential. Its ravages cannot be prevented by the physician alone or by the patient alone. The early recognition of this important fact, particularly by the late Dr. Robert B. Greenough, has done much for the 400,000 sufferers from cancer now in this country and has saved many from disability and death.

It is unnecessary to call attention to the importance of the cancer problem. There is, however, need to emphasize what has been accomplished and what yet remains to be accomplished in the control of this menace. It is well to realize what advances have been made through the co-operative effort of the medical profession, public-health authorities, and intelligent and enthusi-

astic groups of laymen. In Massachusetts we have four special hospitals for cancer and over a hundred cancer clinics. We have alert and interested groups of laymen representing large numbers of organizations co-operating with the Massachusetts Cancer Society and the Massachusetts Department of Public Health and looking toward even more adequate cancer control. The widespread effort of the American Society for the Control of Cancer through the past years and its recent special emphasis on the education of women with regard to the dangers of cancer through the Women's Cancer Army constitute real contributions to the cancer control program.

It is as important in the education of laymen to teach them that cancer is curable as it is to teach them other essential facts. To give added emphasis to this important educational aspect, the Massachusetts Cancer Society is holding at the cancer clinics throughout the State during this month a session largely devoted to the cases of this disease—the most concrete evidence of the practical accomplishments of the cancer drive that we can hope to have.

The death rate in Massachusetts from cancer for women between twenty and sixty years has dropped from 119 per 100,000 in 1927 to 87 in 1937. Twenty-four per cent of the patients with cancer are alive ten years after attending the cancer clinics. Last year eighty-six per cent of the patients attending clinics were referred by physicians, and one thousand three hundred and four physicians attended the sixty-nine teaching clinics.

The Massachusetts Medical Society and the Department of Public Health may well be proud of this record of accomplishment through co-operative effort, and look forward to even more progress in the years to come.

In this number of the *Journal* is an article by Dr. Herbert L. Lombard, covering one of the most fundamental, most controversial and far-reaching aspects of the whole cancer problem—the role of heredity in relation to the occurrence of the disease in human beings. Dr. Lombard's study of the population of one of our smallest states has been most careful and most complete.

Journal takes pride in being able to present to its readers this study of the hereditary aspect of cancer as its contribution toward nation-wide efforts at control of this disease

GASTROSCOPY AND PERITONEOSCOPY

ENDOSCOPIES are being more generally used and are assuming an increasingly important role in the practice of medicine. Bronchoscopy, esophagoscopy, thoracoscopy, cystoscopy, and proctoscopy are standardized procedures in their respective fields, and new endoscopic technics, notably gastroscopy and peritoneoscopy, have been reported as being extremely successful.

Although efforts to see the interior of body cavities were made as early as 1795, gastroscopy was not attempted until 1868, when Kussmaul passed a rigid gastroscope in a professional sword swallower. Because of insufficient illumination the examination was unsuccessful. Various types of gastroscopes were then developed, most of them of the straight rigid variety, but as these were difficult to introduce safely into the stomach, gastroscopy developed very slowly. It was not until 1932, when the Wolf-Schindler¹ flexible gastroscope was first demonstrated, that gastroscopy became generally recognized as a safe and valuable method of examination.

Schindler's work on gastroscopy is outstanding. In addition to his part in the invention of the instrument, he has written extensively on the subject in the current literature and has recently published an excellent book on gastroscopy.² Henning³ and Moutier⁴ have also contributed to the literature on gastroscopy. Benedict⁵ at the Massachusetts General Hospital was the first in this country to use the flexible gastroscope and to call attention to its value in the diagnosis of gastric lesions. According to these authors gastroscopy will give information about the gastric mucosa which cannot be obtained by any other method.

Chronic gastritis is the commonest disease of the stomach. Gastroscopy, by showing the finer changes in the mucosa, is indispensable in its diagnosis. By no other method can edema, color

changes, verrucous elevations, erosions and superficial ulcerations be demonstrated. Superficial, hypertrophic and atrophic gastritis can be differentiated. The improvement after liver therapy in the atrophic gastritis associated with pernicious anemia has been shown by gastroscopic examination.⁶ Careful gastroscopic study of the mucosa in patients with unexplained hematemesis has frequently demonstrated a gastritis with erosions as the source of the hemorrhage.⁷ In fact, it is quite probable that in many cases of peptic ulcer with hemorrhage the source of the bleeding is the associated gastritis rather than the ulcer. Thus in the medical or surgical management of gastric or duodenal ulcer, gastroscopic examination is of great importance since it determines the degree of associated gastritis.

Gastric ulcer, especially the superficial ulcer, is being revealed by gastroscopy to be commoner than has been generally supposed. The gastroscope has been positively shown to be of assistance in the differential diagnosis of ulcer and cancer, for in the living tissue ulcer presents a smooth, sharp margin with a clean yellow or gray base, whereas carcinoma presents a nodular or infiltrated margin and a dark, dirty-appearing one. Another field of usefulness for the gastroscope is in the early diagnosis of cancer. When every patient over thirty-five years of age and complaining of anorexia is examined by gastroscopy, there will be an increase in the early diagnosis of cancer. Careful x-ray examination should be performed in all cases. Gastroscopic and roentgenologic examinations are not competitive, but complementary. Only by the use of both methods can the clinician do full justice to his patient. Gastroscopic examination has already added very important information to our knowledge of the stomach and its increasing usefulness is assured.

Peritoneoscopy, although in some respects appearing simpler and more direct than gastroscopy, was not undertaken until 1901, when Kelling⁸ first used a cystoscope to examine the abdominal cavity of a living dog. While the development of gastroscopy was delayed chiefly because of the inherent difficulty of introducing a rigid tube into

the stomach, peritoneoscopy was delayed probably not because it was so difficult but because exploratory laparotomy was so easy. Surgical exploration is certainly easy for the surgeon, but not for the patient. How many physicians would submit themselves to exploratory operation if any other simpler method would give the desired information? Elsewhere in this issue of the *Journal*, Benedict points out that, whereas exploratory laparotomy is a major operation usually performed under general anesthesia, peritoneoscopy is a minor procedure always performed under local anesthesia. Biopsy can be obtained by both methods. Exploration will of course give more complete information than peritoneoscopy in many cases, but in others the latter will give all the information required. If peritoneoscopy is successful, laparotomy may be avoided, if it fails, exploration can then be carried out. The two methods are not in competition each has its own field, and one supplements the other.

Most writers agree that peritoneoscopy is chiefly useful in cases with abdominal cancer, cirrhosis, tuberculous peritonitis, ascites, pelvic tumors and ectopic pregnancy. It may be indicated in any abdominal or pelvic condition where the diagnosis is obscure or where additional information is needed to confirm a diagnosis or to plan treatment.

Ruddock⁹ recently reported five hundred cases examined by peritoneoscopy, with eight complications (1.6 per cent) and one death (0.2 per cent). All the complications were punctures of the bowel or stomach due to adhesions to the abdominal wall, and all were followed by immediate laparotomy and uneventful recovery. The death was due to hemorrhage from insufficient coagulation of a biopsy wound in metastatic carcinoma of the liver. It is the opinion of Ruddock⁹ that "the mobility of the intestines in the living subject is such that they will not sustain injury but will recede or slip aside before the gentle and slow thrust of the trocar." In each case of puncture of the bowel reported by Ruddock, "the trocar could have been removed without soiling the peritoneal cavity, as the bowel was firmly plastered against the parietal peritoneum."

According to Ruddock⁹ the peritoneoscopic accuracy in his tabulated cases was 92 per cent as compared with a clinical accuracy of 64 per cent. The most striking results were in suspected cancer of the liver and ectopic pregnancy.

Any methods as safe and easy to perform as gastroscopy and peritoneoscopy and which will give a very definite increase in diagnostic accuracy are worthy of a permanent place in the practice of medicine. While not intended for use by the general practitioner, both methods should be available in every medical center.

CHILD HEALTH DAY

This year marks, if not the tenth anniversary of Child Health Day, at least the tenth anniversary of the congressional resolution of May 18, 1928, which authorized the President to proclaim May Day as Child Health Day. The two ideas have become inseparably associated in our minds—the day that marks the incoming of the first really spring month in our northern states, and the day that we have accepted on which to acknowledge our obligation to the oncoming generation.

There is much that we cannot guarantee to the children of the Nation today that we felt, ten years ago, would be theirs by the very fact of American birth—a possibility of peaceful existence, a fighting chance for economic security, stability in government. The foundation that had then been laid was apparently not capable of supporting a permanent structure, but despite our economic quicksands we have continued each year to sink a few caissons that we hope will bear permanent results in the form of improved child health and a greater understanding of the problems of childhood.

M. FLETCHER EADES, M.D., *Secretary*
19 Bay State Road
Boston,

CASE HISTORY No 69 PREMATURE SEPARATION
OF THE PLACENTA

Mrs C M., a thirty-year-old multipara, was admitted to the hospital as an emergency case for the treatment of vaginal hemorrhage of three hours' duration. She was in the seventh month of a pregnancy which had been entirely normal up to the day of entry. She had observed enlargement of the abdomen following the onset of bleeding. External hemorrhage had been slight.

There was no family history of diabetes, tuberculosis, cancer or cardiorenal disease. The patient gave no history of scarlet fever, diphtheria, typhoid or rheumatic fever, and the rest of her past history was also negative. There was no specific catamenial history, and the date of her last period was not recorded.

On physical examination the patient was apprehensive, and the skin cold and clammy, the mucous membranes demonstrated definite pallor. The pupils were equal and active and reacted to light and accommodation. The mouth was clean, and the teeth carious and discolored, the tongue protruded in the midline without tremor. The thyroid was palpable, its contour smooth and symmetrical. The chest expanded normally, and the lungs were resonant, the breath sounds were normal, and there were no rales. The heart was not enlarged, the sounds were of fair quality, and there was a systolic murmur at the apex. The rate was 124, and the blood pressure was 118 systolic, 102 diastolic. Examination of the abdomen disclosed a rounded abdominal tumor, the size of a full-term intrauterine pregnancy, which was tense and tender. Fetal outlines could not be mapped out, and it was impossible to distinguish the fetal heart beat. The pelvic measurements were I C 28 cm, I S 25 cm, E C 19.5 cm, and outlet 9.5 cm. There was only slight oozing of dark blood from the vagina. Rectal examination revealed the cervix to be dilated three fingerbreadths, but not taken up. The presenting part was high.

The patient was transferred to the operating room and prepared for immediate delivery. The cervix was manually dilated under full ether anes-

thesia to admit the closed fist. The fetal membranes were then ruptured, when a large amount of bloody fluid came away. Internal podalic version and breech extraction were performed without difficulty. The baby was stillborn and weighed 4 lb., 3 oz. The placenta was completely separated and was expressed with the membranes intact. There was profuse hemorrhage following its expulsion. Inspection of the cervix revealed deep bilateral lacerations. The tears were sutured with interrupted chromic catgut.

The patient was returned to bed in poor condition. The pulse rate, which had been 160 during delivery, was 144 a half hour later. Two hours after delivery the blood pressure was 85 systolic. She was placed in Trendelenburg position and given caffeine and camphor in oil, 500 cc. of normal saline was given under each breast. A rectal tap was not retained. She did not respond to stimulation and expired three hours postpartum, without transfusion.

Comment This case represents the treatment of separated placenta twenty years ago. Accoucheement forcé was, at that time, a very common operation, and the result illustrated in this case too often occurred. The cervix does not tolerate rapid dilatation. Undoubtedly this patient had a rupture of the lower segment of the uterus as a result of manual dilatation. Today this patient would have been delivered by the conservative method of rupturing the membranes and applying a Spanish windlass. Her blood would have been grouped and cross matched, and a compatible donor would have been available, she would have been transfused, and retransfused if necessary.

LEGISLATIVE NOTES

During the past week the following changes have taken place in the bills before the Legislature in which the Society is interested.

On House Bill 56, which further regulates the conditions under which food may be manufactured, the Legislature has voted 'no legislation necessary.'

House Bill 1852, which is a redraft of House Bill 51, has been passed to be engrossed. This bill relates to the control of diseases dangerous to public health.

Senate Bill 361, a bill to issue certificates of approval of bacteriological laboratories, has been given 'leave to withdraw.'

House Bill 41, requiring the annual licensing of qualified physicians, has been voted 'no legislation necessary' by the Legislature.

House Bills 818 and 819, both relating to the commitment of insane persons, have been reported out of committee. Its report of 'leave to withdraw' has been accepted in the House.

House Bill 1845, a redraft of House Bill 758, has been passed by the Legislature. This bill postpones the effective date of Chapter 247, of the Acts of 1936, to January 1, 1941.

MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning May 2

BRISTOL SOUTH (Fall River Section)

Monday, May 2, at 4 30 p. m., at the Union Hospital, Fall River Subject Acute Anterior Poliomyelitis—Its Diagnosis and Treatment. Instructor Charles F. McKhann, Jr. Howard P. Sawyer and Robert H. Goodwin, *Chairmen*

ESSEX NORTH

Friday, May 6, at 4 30 p. m., at the Lawrence General Hospital, Lawrence. Subject Acute Anterior Poliomyelitis—Its Diagnosis and Treatment. Instructor R. Cannon Eley. John Parr, *Chairman*

MIDDLESEX SOUTH

Wednesday, May 4, at 4 00 p. m., at the Cambridge Municipal Hospital, Cambridge Street, Cambridge. Subject Puerperal Sepsis. Instructor Christopher J. Duncan. Edmund H. Robbins, *Chairman*

DEATHS

FISHER—EDGAR A. FISHER, M.D., of Worcester, died April 17 at his home. He was in his seventy third year.

Born in Nantucket, he attended Boston University School of Medicine, receiving his degree in 1887. He began his practice in Worcester shortly afterward. About fifteen years ago he gave up general practice to devote his time to surgery. Dr. Fisher was one of the small group that founded Hahnemann Hospital in Worcester, where he was chief of the surgical department, vice president of the board of directors and a member of the governing board of the hospital. Among his affiliations were fellowships in the American Medical Association, the Massachusetts Medical Society and the American College of Surgeons. He held membership in the University Club of Worcester and was a member of the Masonic Order and the Odd Fellows.

His widow survives him.

RAND—RICHARD B. RAND, M.D., of North Abington died April 19. He was in his seventy first year.

A native of Hanover, New Hampshire, he graduated from Dartmouth College and received his degree from Dartmouth Medical School in 1893. Dr. Rand had practiced for forty six years in North Abington.

He was a fellow of the Massachusetts Medical Society and a member of the American Medical Association. He was a member of the Masonic Order.

His widow and two daughters survive him.

WALKER—WILLIAM D. WALKER, M.D., of 121 Main Street, Andover, died April 12. He was in his sixty first year.

A native of St. John, New Brunswick, he was the son of Dr. Thomas Walker, physician surgeon and colonel of the 62d regiment of Canadian militia. He received his degree from Tufts College Medical School in 1905. He served as school physician at Andover for many years and was on the school committee for six years.

Dr. Walker was a fellow of the American Medical Association and the Massachusetts Medical Society. His

memberships included the Lawrence Medical Club and the Essex North District Medical Society, of which he was president.

MISCELLANY

NOTES

The Massachusetts General Hospital announces that the Warren Triennial Prize for the year 1937, founded in 1867 by the late Dr. J. Mason Warren in memory of his father, amounting to five hundred dollars, has been awarded to Dr. Henry K. Beecher for a manuscript entitled "The Physiology of Anesthesia."

In all, twelve essays were submitted in competition from persons in various parts of the United States, England and Germany.

Dr. Beecher at the present time holds the position of anesthetist at the Massachusetts General Hospital.

The following promotions in the faculty at Harvard Medical School, effective next September 1, were recently announced: Fuller Albright, assistant professor of medicine, Samuel L. Gargill, associate in medicine, T. Duckett Jones, associate in medicine, Wyman Richardson, associate in medicine, and John C. Whitehorn, associate in psychiatry.

CORRESPONDENCE

A RESOLUTION

To the Editor—At the meeting of the Boston Society of Psychiatry and Neurology on April 21, the following resolution was unanimously passed and I was instructed to send a copy of it to the Governor, the members of his council, and the *New England Journal of Medicine*:

Inasmuch as the administration of public health is a special branch of medicine, be it resolved that in the selection of the Commissioner of Public Health for the Commonwealth of Massachusetts, the Governor nominate for commissioner a physician who by special training and experience in the administration of public health is qualified to assume the responsibilities of this important office.

H. HOLSTON MERRITT, M.D., *Secretary*

Boston Society of Psychiatry and Neurology

923 Medical Building,
Boston City Hospital,
Boston, Massachusetts

INADEQUATE MEDICAL CARE

To the Editor—May I call attention to an error in the article by Rosco G. Leland, published in the *Journal* of March 24, 1938. On page 519 of that issue Dr. Leland says:

A survey of some 35,600 persons made by the Committee on the Costs of Medical Care showed that 47.1 per cent had no illness over a period of more than a year. The study also showed that 47.9 per cent of these persons had the services of physicians. Only 5 per cent of the persons involved in the survey were presumably in need of medical services but for some reason did not avail themselves of medical care. Perhaps 5 per cent is not too large an estimate of those who because of human characteristics manifested as ignorance, stupidity or prejudice prefer cultism, patent medicine, the advice of friends or relatives or no medical service at all.

The survey made by the Committee on the Costs of Medical Care is contained in Volume 26 (University of Chicago Press, 1933) of its publications. A study of this report shows that 5 per cent is entirely incorrect as a figure indicating the unmet need for medical care among these 38,600 persons. Dr Leland's statement gives the impression that 47.9 per cent of the surveyed population had the services of physicians as required during the year. An examination of the report shows that this is not the meaning of this percentage. The 47.9 per cent includes merely those persons who had a physician one or more times during the year, irrespective of the number or gravity of their illnesses. A woman, for instance, who had one visit from a doctor at the time of delivery, with no prenatal or postpartum care, would be in the 47.9 per cent. A child having scarlet fever, an infected ear and a cut hand at different times during the year, and who had a physician once, would be in the 47.9 per cent.

The article thus misinterprets the "47.9 per cent." The survey showed that this 47.9 per cent of the people reported an average of over one and a half illnesses per person, and that, *measured in terms of the number of illnesses receiving care*, 22.4 per cent of all the illnesses had no care from physicians or anyone else. Moreover, the percentage of illnesses receiving care varied with different income groups. Among persons with family incomes of \$10,000 and over, 7.3 per cent of the illnesses were uncared for. In the \$1200 to \$2000 income group, 25 per cent of the illnesses were uncared for, and in the income group under \$1200, 33.5 per cent.

Thus, the survey from which Dr Leland quotes does not bear out his implication, cited above, that "only 5 per cent of the persons involved in the survey were presumably in need of medical services but for some reason did not avail themselves of medical care." On the contrary, the survey showed that the amount of unmet medical need was much larger than this. Several more recent surveys, such as those just completed by the United States Public Health Service and the California Medical Association, show similar or larger percentages of illness not receiving any medical care and are the more striking because these deal with disabling illnesses only.

A WOODEN ARTERIAL CAST

To the Editor In 1683 Roger Williams was buried at the foot of an apple tree. While digging the grave of his grandchild in 1710, the head end was knocked from his coffin, and when his grave was opened in 1860, it was found that rootlets of the tree had invaded the aorta

and shot downward, following the arterial track to and beyond the feet. By the time that the legs were reached there must have been sufficient decomposition for the roots to spread beyond the area of the actual arteries, but the cast is pretty accurate in its upper portion.

This is probably the only known cast in wood of the circulatory system. The relic is preserved by the Rhode Island Historical Society in Providence, the accompany-

ing picture was published in the Society's *Collections* for April, 1936, and is reprinted with its kind permission.

HAROLD BOWDITCH, M.D.

520 Commonwealth Avenue,
Boston.

REPORT OF MEETING

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on February 8, Dr Henry A. Christian presiding.

The surgical case was presented by Dr P. D. Giddings. The patient, a seventy-year-old white male, had experienced pain, numbness and tingling in both lower legs for the past two years, and had been previously hospitalized because of impending gangrene of his right foot. On entry his feet were found to be cold and cyanotic. In spite of paravertebral alcohol injection at the level of the second lumbar vertebra, resection of the peroneal and sural nerves, and supportive treatment, an area of gangrene developed on the dorsum of the right foot. Dr Elliott C. Cutler discussed the case and stated that amputation of the foot was the advisable procedure.

The medical case was a seventy-one-year-old white female, whose mother had died of anemia at the age of thirty-two, and whose sister had died of pernicious anemia at the age of sixty-nine. One year previously she was seen in the hospital because of recurrent weakness, and her red-blood-cell count was found to be only 900,000. She received intramuscular injections of liver extract, and her red-cell count rose to 2,000,000. Six weeks before her present entry she experienced ataxia, tinnitus, dyspnea and vomiting. Her local physician found her red-cell count to be below 1,000,000 and advised hospitalization. At entry she was found to be dyspneic, pale and slightly icteric, but well oriented. She had an atrophic glossitis, systolic pulmonary and diastolic apical and basal murmurs, diminished to absent vibratory sensation in both legs, absent knee and ankle jerks, and slight ankle edema. The hemoglobin was 22 per cent (Sahli), and the red-cell count 700,000, with a hematocrit of 13 per cent. The blood smear was typical of pernicious anemia in relapse; there were 2.4 per cent reticulocytes. She received 2.0 cc. of concentrated liver extract intramuscularly, and on the seventh day the red-cell count had risen to 2,200,000, and the hemoglobin to 54 per cent; there were 41 per cent reticulocytes. The basal metabolic rate was +33 four days after admission.

Dr Robert T. Monroe remarked that pernicious anemia could make its first appearance at a very late age, and stated that he had recently seen an eighty-six-year-old patient in his first relapse. Dr Christian commented on the elevated basal metabolic rate which is frequently seen in patients with severe anemia, and which falls toward normal with improvement in the condition of the blood. In spite of the marked elevation of metabolism these patients are usually well nourished.

Dr Walter B. Cannon, George Higginson Professor of Physiology, presented the paper of the evening on the subject "The Aging of Some Homeostatic Mechanisms." Dr Cannon pointed out that, as the span of life is being lengthened by the application of our knowledge of hygiene and preventive medicine, more and more persons are reaching the older age groups and the diseases of old age are becoming of increasing importance. Dr Cannon has recently undertaken a study of the changes that occur in the body's ability to maintain a 'steady state'.

with increasing age. As examples of such homeostatic mechanisms he selected the maintenance of constant temperature, blood sugar and acid-base balance.

The first of these mechanisms, heat regulation, shows marked restriction with advancing years. Uniform body temperature is maintained by a delicate balance between heat production and heat loss, either process being accelerated or decreased as the need arises. Observations have shown that the temperatures of elderly people are not much different from those of the young, although there is a steady decrease in heat production with advancing age. Boothby found a progressive decrease in the calories produced per hour per square meter of body surface with increasing age—a decrease amounting to 24 per cent in persons eighty years of age. The explanation for this decrease is possibly due to involuntional changes which occur in the thyroid gland with advancing age, and to the reduced bodily activity and consequent lessened heat production. Elderly persons protect themselves against cold outer environment and decreased heat production by putting on more clothing and by seeking a sheltered existence. The output of heat from the body surface is decreased by atrophy of the skin and partial disappearance of the dermal capillaries. There is also a partial degeneration of the sweat and oil glands, and a thickening of arteriolar walls leading to a less ready discharge of heat from the body surface—factors causing a diminished ability of the aged to withstand high temperatures. This limitation of homeostasis is evidenced by the steady increase in incidence of heat stroke with increasing age.

The constancy of the blood sugar, ordinarily maintained between very definite limits, tends toward greater and greater variation with advancing years. Porter and Langley found that although there was normally no glycosuria in individuals between the ages of thirty and forty, 40 per cent of persons aged sixty to seventy showed an occasional glycosuria. John showed that with increasing age more and more individuals had a diabetic or prediabetic type of glucose tolerance curve.

One of the most remarkably constant factors in the body is the maintenance of the acid-base balance. The pH of the plasma is maintained at 7.4, and variations of only a few tenths of a pH are sufficient to cause tetany or coma. One of the important factors in maintaining this constancy is the ability of the lungs to rid the blood of excess carbon dioxide. With advancing age there is a decrease in the respiratory efficiency of the lungs; the vital capacity at the age of sixty to sixty five is only 80 per cent of the value at thirty to thirty five. The body can no longer take in and push out large quantities of air. Associated with this limitation of vital capacity there is also a limitation of the amount of air that can be breathed in and out during extreme physical effort, and there is a greater tendency for the accumulation of carbon dioxide in the blood in elderly persons. This decrease in respiratory efficiency is due to the weakening of the intercostal muscles and increasing rigidity of the thoracic cage.

With increasing age there is an increase in systolic blood pressure, and loss in the elasticity of the arteries, amounting to a reduction of about 60 per cent in the latter case at the age of eighty. Capillaries lose their ability for ready and complete dilatation, and there is increase in pericapillary connective tissue preventing rapid diffusion of oxygen and waste products between parenchymal cells and capillaries. Limitations of acid-base regulation are contributed to by changes in the heart, which reacts to strain in old age by dilating and thus empties incompletely and inefficiently. The heart of the aged also shows lessened ability to accelerate. These factors decrease the

body's ability to provide adequate circulation for severe strains, and tend to cause the accumulation of waste products. The oxygen carried away from the lungs during maximal work drops some 34 per cent between the ages of seventeen and sixty-three, while the lactic-acid content of the blood in similar circumstances is three times greater in the elderly person.

Dr Cannon's observations of the limitations of the body mechanisms are confirmed by the results reported in competitive sports. Records for the 100-yard dash are all made by young adults, the world record was made by Wykoff at the age of twenty-one. As the requirement for rapid effort becomes less and the demand for endurance and judgment increases, there is an increase in achievement with age, as is demonstrated by the ages of those holding world records in runs of different distances: the records for the 1- to 5-mile runs are held by men from twenty-three to twenty-seven years of age, the 10-mile record was set by Nurmi at the age of thirty-one. The best Marathon performances by De Mar were between the ages of thirty-six and forty-two. Tennis players reach their peak between the ages of twenty-five and thirty, and after that begin to "slow up" in their ability to adjust to severe strain. After the age of thirty-five, baseball players slow up because of the beginning failure of their lungs, hearts and vascular systems.

In summary, Dr Cannon stated that with increasing age the homeostatic mechanisms maintaining the constant *interior milieu* become less able to meet excess demands, and necessitate a more sheltered, less active existence. Involuntional and degenerative changes in the body tissues and organs are responsible for these limitations of homeostasis in the elderly.

NOTICES

MASSACHUSETTS ITALIAN MEDICAL SOCIETY

The next meeting of the Massachusetts Italian Medical Society will be held on Friday, April 29, at the Hotel Kenmore, Boston, at 9 15 p. m. *Note change from usual date of meeting*

PROGRAM

Presentation and Discussion of Medical and Surgical Cases in Practice.

Dr. Arthur B. Emmons, 2d, will speak on the work of the Boston Health League, Inc., on occupational hygiene.

The medical profession is invited to attend.

CARL F. MARALDI, M.D., *Secretary*

NATIONAL HOSPITAL DAY

The New England Hospital Association and the Massachusetts Hospital Association are working together with the National Committee of the American Hospital Association in the observance of National Hospital Day, Thursday, May 12.

Many hospitals are making extensive plans in the observance of this day. Hospitals throughout New England will have "open house" in order that former patients and friends may visit the hospital to see the latest scientific equipment and apparatus used in the modern treatment of patients.

All members of medical societies are urged to cooperate with hospital administrators by taking part in

The survey made by the Committee on the Costs of Medical Care is contained in Volume 26 (University of Chicago Press, 1933) of its publications. A study of this report shows that 5 per cent is entirely incorrect as a figure indicating the unmet need for medical care among these 38,600 persons. Dr Leland's statement gives the impression that 47.9 per cent of the surveyed population had the services of physicians as required during the year. An examination of the report shows that this is not the meaning of this percentage. The 47.9 per cent includes merely those persons who had a physician one or more times during the year, irrespective of the number or gravity of their illnesses. A woman, for instance, who had one visit from a doctor at the time of delivery, with no prenatal or postpartum care, would be in the 47.9 per cent. A child having scarlet fever, an infected ear and a cut hand at different times during the year, and who had a physician once, would be in the 47.9 per cent.

The article thus misinterprets the "47.9 per cent." The survey showed that this 47.9 per cent of the people reported an average of over one and a half illnesses per person, and that, *measured in terms of the number of illnesses receiving care*, 22.4 per cent of all the illnesses had no care from physicians or anyone else. Moreover, the percentage of illnesses receiving care varied with different income groups. Among persons with family incomes of \$10,000 and over, 7.3 per cent of the illnesses were uncared for. In the \$1200 to \$2000 income group, 25 per cent of the illnesses were uncared for, and in the income group under \$1200, 33.5 per cent.

Thus, the survey from which Dr Leland quotes does not bear out his implication, cited above, that "only 5 per cent of the persons involved in the survey were presumably in need of medical services but for some reason did not avail themselves of medical care." On the contrary, the survey showed that the amount of unmet medical need was much larger than this. Several more recent surveys, such as those just completed by the United States Public Health Service and the California Medical Association, show similar or larger percentages of illness not receiving any medical care and are the more striking because these deal with disabling illnesses only.

A WOODEN ARTERIAL CAST

To the Editor In 1683 Roger Williams was buried at the foot of an apple tree. While digging the grave of his grandchild in 1710, the head end was knocked from his coffin, and when his grave was opened in 1860, it was found that rootlets of the tree had invaded the aorta

and shot downward, following the arterial track to and beyond the feet. By the time that the legs were reached there must have been sufficient decomposition for the roots to spread beyond the area of the actual arteries, but the cast is pretty accurate in its upper portion.

This is probably the only known cast in wood of the circulatory system. The relic is preserved by the Rhode Island Historical Society in Providence, the accompany-

ing picture was published in the Society's *Collections* for April, 1936, and is reprinted with its kind permission.

REPORT OF MEETING

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on February 8, Dr Henry A. Christian presiding.

The surgical case was presented by Dr P. D. Giddings. The patient, a seventy-year-old white male, had experienced pain, numbness and tingling in both lower legs for the past two years, and had been previously hospitalized because of impending gangrene of his right foot. On entry his feet were found to be cold and cyanotic. In spite of paravertebral alcohol injection at the level of the second lumbar vertebra, resection of the peroneal and sural nerves, and supportive treatment, an area of gangrene developed on the dorsum of the right foot. Dr Elliott C. Cutler discussed the case and stated that amputation of the foot was the advisable procedure.

The medical case was a seventy-one-year-old white female, whose mother had died of anemia at the age of thirty-two, and whose sister had died of pernicious anemia at the age of sixty-nine. One year previously she was seen in the hospital because of recurrent weakness, and her red-blood-cell count was found to be only 900,000. She received intramuscular injections of liver extract, and her red-cell count rose to 2,000,000. Six weeks before her present entry she experienced ataxia, tinnitus, dyspnea and vomiting. Her local physician found her red-cell count to be below 1,000,000 and advised hospitalization. At entry she was found to be dyspneic, pale and slightly icteric, but well oriented. She had an atrophic glossitis, systolic pulmonary and diastolic apical and basal murmurs, diminished to absent vibratory sensation in both legs, absent knee and ankle jerks, and slight ankle edema. The hemoglobin was 22 per cent (Sahli), and the red-cell count 700,000, with a hematocrit of 13 per cent. The blood smear was typical of pernicious anemia in relapse, there were 24 per cent reticulocytes. She received 2.0 cc. of concentrated liver extract intramuscularly, and on the seventh day the red-cell count had risen to 2,200,000, and the hemoglobin to 54 per cent, there were 41 per cent reticulocytes. The basal metabolic rate was +33 four days after admission.

Dr Robert T. Monroe remarked that pernicious anemia could make its first appearance at a very late age, and stated that he had recently seen an eighty-six-year-old patient in his first relapse. Dr Christian commented on the elevated basal metabolic rate which is frequently seen in patients with severe anemia, and which falls toward normal with improvement in the condition of the blood. In spite of the marked elevation of metabolism these patients are usually well nourished.

Dr Walter B. Cannon, George Higginson Professor of Physiology, presented the paper of the evening on the subject "The Aging of Some Homeostatic Mechanisms." Dr Cannon pointed out that, as the span of life is being lengthened by the application of our knowledge of hygiene and preventive medicine, more and more persons are reaching the older age groups and the diseases of old age are becoming of increasing importance. BOOK REVIEWS

Fever Therapy Abstracts and discussions of papers presented at the First International Conference on Fever Therapy March 29, 30 31, 1937 Walter M. Simpson, William Bierman, et al. 486 pp New York Paul B. Hoeber, Inc., 1937 \$5.00

This book is a presentation of abstracts of the papers presented at the First International Conference on Fever Therapy, which was held in New York City in March, 1937. The abstracts are printed in English, French and German, but the discussions are presented only in English.

The volume contains messages of greeting from President Roosevelt, Professor Julius Wagner-Jauregg, Professor A. D. Arsonval and Baron Henri de Rothschild, the latter three being pioneers in this type of therapy. There then follows a discussion of the various methods of producing fever in the body, and it is quite obvious that there is no

clinical demonstrations and lectures that may be of interest to the lay public.

Time has been reserved on the air for May 10 and 11, and medical men have been secured to talk on "Our Hospitals"

JOSEPH P. LEONE, M.D.,
National Hospital Day Chairman,
Massachusetts Hospital Association

NORFOLK DISTRICT MEDICAL SOCIETY

The eighty-eighth annual meeting of the Norfolk District Medical Society will be held at the Hotel Somerset, Boston, on Tuesday, May 3

The business meeting will begin at 6 00 p. m., dinner will be served at 6 45. Following the dinner, there will be a lecture, beautifully illustrated in color, entitled "The Land of the Aztecs. The story of Mexico, ancient and modern," by Dr. Charles H. Tozier, of Winchester

NUMBER 18

SULFANILAMIDE IN THE TREATMENT OF ACUTE GONOCOCCAL URETHRITIS CLINICAL AND IMMUNOLOGICAL OBSERVATIONS

WESLEY W. SPINK, M.D.* AND EUGENE A. GASTON, M.D.†

BOSTON

SULFANILAMIDE, originally introduced for the treatment of patients with *Streptococcus hemolyticus* infections, has been reported as effective in other types of bacterial infection, such as those due to the meningococcus and the gonococcus. No attempt will be made in this report to review the voluminous literature pertaining to the use of the drug. This has been adequately done by others^{1 2 3 4 5 6 7}

There are relatively few reports on the use of sulfanilamide in the treatment of gonococcal infections. Dees and Colston⁸ recently summarized their results of treatment in 47 cases with various types of gonococcal infections of the genitourinary tract. In 36 cases, gonococci and the urethral discharge disappeared in less than five days after the administration of sulfanilamide. In 5 cases, although there was a diminution of symptoms, gonococci remained persistently present. In 3 cases there was no clinical response to the drug. In 3 other cases there was a prompt therapeutic response, but with omission of the drug there was a recurrence of symptoms, which disappeared in 2 of the cases when it was resumed. Dees and Colston encountered no serious reactions to the drug, and concluded that it would prove of great value in the treatment of gonococcal infections.

More recently, Reuter⁹ treated 100 cases of varying types of gonorrhea. Recovery occurred in 93 per cent of the fresh cases, and in 88 per cent of the previously treated ones. Reuter observed a number of side effects due to the drug, and sounded a warning against its indiscriminate use. It may be pointed out here that although the Council on Pharmacy and Chemistry of the American Medical Association accepted sulfanilamide in its *New*

and Nonofficial Remedies, they stated that certain undesirable side effects might follow its administration. These include acidosis, jaundice, urticaria, sulfhemoglobinemia, methemoglobinemia, granulocytopenia and hemolytic anemia.¹⁰

The present report is concerned with the results of treatment and with immunological observations in 21 men with acute gonococcal urethritis. The patients were ambulatory. Eight of them had received previous treatment without diminution of their symptoms.

METHODS OF STUDY

The clinical course was carefully followed before and after the administration of sulfanilamide. The diagnosis of gonorrhea was established by the presence of a purulent urethral discharge, stained smears of which revealed gram-negative intracellular diplococci. Subsequent to the administration of sulfanilamide, the patients were examined daily for the first few days, and then at intervals of two to three days. At each visit they were carefully examined and questioned concerning signs and symptoms attributable to the drug. The character of the urethral discharge was noted. A two-glass test of the urine was done. Stained smears of the urethral discharge were studied microscopically for gonococci and leukocytes. If the patient's course progressed favorably, the prostate was massaged, and the prostatic secretion was examined for gonococci and leukocytes.

The second method of approach consisted in serological and immunological observations of the blood. Gonococcal complement-fixation tests were done before the administration of sulfanilamide and at intervals during and after treatment. A blood Hinton test for syphilis was done when the patient was first seen.* The bactericidal action of whole defibrinated blood against strains of gonococci was determined according to the method of

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital; the Department of Medicine, Harvard Medical School; and the Genitourinary Out Patient Department, Boston City Hospital.

Formerly resident physician, Thorndike Memorial Laboratory, Boston City Hospital; now assistant professor of medicine, University of Minnesota Medical School.

*Formerly resident surgeon, Boston City Hospital; now in practice, Framingham, Massachusetts.

The tests were done by the Wassermann Laboratory of the Massachusetts Department of Public Health (Dr. William A. Hinton, director).

unanimity of opinion in regard to the most satisfactory way of producing fever from a therapeutic point of view. From reading these discussions, however, it seems likely that mechanical devices are going to be used more in the future than protein shock or the artificial production of definite disease, such as malaria.

There is a series of abstracts on some of the physiologic changes which occur in the body as a result of induced fever. These studies concern chiefly the effects upon blood volume, acid base balance, chloride balance and reactions in bone marrow, connective tissue and lymph nodes.

The next series of papers covers the effect of fever therapy in miscellaneous diseases. In addition to many individual infections, some of known and some of unknown etiology, this form of therapy has been tried in psychiatric patients and those with ophthalmologic, otolaryngologic and other diseases that are grouped among the specialties. The benefits of treatment in all these diseases are by no means established or claimed by the authors. That it is advantageous in certain infections, such as syphilis and gonorrhea, has been quite definitely proved.

The book awakens one's interest in the possible benefits of fever therapy in the treatment of a variety of diseases.

Radiation Therapy Its use in the treatment of benign and malignant conditions Oxford Medical Publications Ira I Kaplan 558 pp New York Oxford University Press, 1937 \$10 00

The author characterizes this volume in the preface as aiming to give the student and general practitioner, as well as the specialist, an understanding of the fundamentals of irradiation, and enumerates the conditions for which this form of therapy is of value.

The first five chapters are devoted to a brief historical review and to the physics of radium, x-ray and electro-surgical apparatus. There then follows a discussion of the treatment of the more common dermatologic conditions, both benign and cancerous. Two chapters are devoted to eye, ear, nose and throat therapy, a great variety of conditions being briefly touched upon.

Separate chapters are devoted to thoracic lesions, breast conditions, the gastrointestinal tract, gynecologic conditions, the genitourinary system, neurologic conditions, endocrinology, inflammatory conditions, diseases of the reticuloendothelial system, blood dyscrasias, sarcomas of the soft tissues and various bone conditions both primary and metastatic.

Brief mention is made of the complications and injuries following irradiation, of the relation of trauma to cancer, and of the nursing care of patients with cancer.

Most of the technic outlined in this book presupposes a considerable supply of radium, emphasis being placed on the use of radium rather than on x-ray. The author recommends that the radium be distributed in applicators of various lengths and strengths, chiefly with platinum filtration. He advises that radium emanations be purchased whenever needed, and points out that radium treatment can be carried out promptly and efficiently with one gram of radium element properly distributed. Emanation need be used only in the form of gold filtered seeds for permanent implantation in lesions not readily accessible to the temporary application of radium element.

The reviewer feels that many of the procedures for which radium is recommended can be more easily and as effectively carried out with high voltage roentgen rays. However, Dr. Kaplan points out that no attempt has

been made to evaluate or even to present all the different methods in use by other therapists.

Health Insurance The next step in social security Louis S Reed. 281 pp New York and London Harper & Brothers, Publishers, 1937 \$3 00

This book is frankly an argument for compulsory health insurance to meet the cost of medical care for the low income groups.

The preface states clearly the conflicting points of view of the medical profession and the general public concerning the problem of providing adequate medical care.

It is stated in the first chapter that adequate medical care is a service which the community has a right to expect to be provided equally with food, shelter and clothes. It is pointed out, however, that the delivery of medical service differs from all other services in the fact that the persons who seek the service or, to quote the author's words, "buy a commodity, are dependent entirely upon the good will of the physician or 'seller,' and that the services are rendered irrespective of the recipients ability to pay. The idealism of the medical profession has made the continuation of this practice possible, although it is recognized by the profession itself and by the public that the idealism has frequently been sacrificed to practical considerations. Physicians, like other members of the community, must earn a living, and the ability of patients to pay for services rendered has exerted a determining influence on the distribution of physicians, who naturally locate in communities where it is probable that they will receive an adequate financial return for their work.

Economic factors are largely responsible for the failure to meet the needs of the community in both preventive and curative medical care. The greatest difficulty arises in the middle income group from catastrophic illness, which imposes a heavy burden at a given time, and upon those of the lowest income group above the indigent class who cannot pay for ordinary medical service.

The author believes that the established methods of private practice are not adapted to the present social order. The payment for medical services through charitable contributions is not likely to continue to the same degree which has obtained in the past. The Government has already invaded the field to a considerable extent. Voluntary health insurance may be provided for certain emergencies, but compulsory health insurance offers the only satisfactory solution. The medical profession must determine what its attitude shall be. "The physician today stands at a crossroads. Through no fault of his own he has been maneuvered into a position where his traditional spirit and ideals are threatened."

The ultimate solution of the problem lies either in state medicine, supported from general governmental revenues, or an insurance plan adapted to the needs of the people in this country. Changes in the method of payment for medical service need not lead to a lower quality of service. "Once the practice of medicine is put upon a solid economic basis, the profession can see that the quality of service is what it ought to be."

The book presents an excellent statement of a point of view which has a wide following in this country. On the whole, the attitude of the medical profession is sympathetically presented, although not, in every instance, clearly expressed. Most physicians will not agree with the final conclusions, but anyone who is interested in the future development of medical practice will find the book illuminating and readable.

showed evidence of cyanosis. One had fever and diarrhea, which abated when the drug was discontinued.

Since a positive gonococcal complement-fixation test of the blood may indicate the presence of humoral antibodies against the gonococcus, we desired to determine whether the drug had any effect upon the development of antibodies dur-

completed, data on only 15 of them are presented. The bloods of 6 of these patients, before sulfanilamide therapy, showed a bacteriolytic titer considerably increased over that of the bloods of the normal controls. The bloods of four normal controls were constantly ineffective in killing the two strains of gonococci in the dilutions used in this study. In 9 patients the bacteriolytic titer, before

Chart 1 The patient received 4 gm. of sulfanilamide for twelve days with marked clinical improvement. Note the increase in the bactericidal power of the patient's whole blood while the drug was being received.

ing the infection. Several complement-fixation tests were done while the drug was being administered. Nineteen of the 21 patients gave positive reactions while under observation. Nine gave negative reactions before receiving sulfanilamide but positive ones while taking it. Eight had positive tests before and after the drug had been prescribed. Two had positive tests before and negative tests during its administration. Two had negative tests before and after taking. From these observations, it would appear that the demonstration of antibodies against the gonococcus by means of the complement-fixation test is not affected by sulfanilamide.

Two patients had evidence of syphilis. Hinton and Kahn tests were positive before and during the administration of sulfanilamide, which suggests that sulfanilamide therapy does not interfere with serological tests for syphilis.

Further immunological studies were carried out by means of bactericidal tests on whole defibrinated blood. Because some of the patients stopped coming to the clinic before these observations were

receiving sulfanilamide, was the same as that of the normal controls but was greatly elevated during its administration. When it was discontinued the bacteriolytic titer promptly fell to normal.

Chart 1 shows the relation between the bacteriolytic titer of a patient's blood and the administration of sulfanilamide. The course of the infection is also illustrated. Before the sulfanilamide was given, the bactericidal power of the blood was approximately the same as that of a normal control. Four grams was then taken daily for twelve days. The bactericidal power increased during this period. When the drug was discontinued, the bacteriolytic titer again approximated that of the normal control.

Chart 2 illustrates the findings in a patient given 4 gm. of sulfanilamide daily for eighteen days. Again, there was a rise in the bacteriolytic titer while he was taking sulfanilamide, and a fall when it was omitted.

Chart 3 shows a marked rise in the bactericidal power of a patient's blood upon taking sulfanilamide. The patient then failed to report to the

Todd, as used by Spink and Keefer¹¹ in studies of gonococcal infections. By means of this test it was shown that bacteriolysins against the gonococcus develop in the blood of patients during the course of infection. Furthermore, it was observed that the titer of bacteriolysins in the blood could be increased considerably by the addition of immune horse serum, both *in vitro* and *in vivo*.^{11, 12} Thus, in a patient with gonococcemia without endocarditis the blood stream was cleared of organisms following the administration of immune serum. Since the presence of bacteriolysins in the blood appeared to be an aid in the destruction of the gonococcus, it seemed logical to determine whether the administration of sulfanilamide increased the bacteriolytic titer of the blood. If such an increase could be demonstrated, many of the complications following a hematogenous spread of gonococci could doubtless be prevented by giving sulfanilamide. The bactericidal test was performed as follows. Varying dilutions of an eighteen-hour suspension of gonococci in broth were added to 0.5 cc of whole defibrinated blood in small pyrex glass tubes. The number of organisms in each tube was determined by the plating of 1 cc of the contents of tubes with dilutions, 10^{-6} and 10^{-7} . The tubes were sealed in a gas-oxygen flame, and rotated for thirty-six hours in a box in an incubator at 37.5°C . The tubes were then opened and the contents were cultured for gonococci. Two strains of gonococci isolated from patients with gonococcal arthritis were used in performing the tests. It was found that defibrinated whole blood of several normal controls was only slightly bacteriolytic for these strains. Bactericidal tests were carried out on the bloods of patients before the administration of sulfanilamide, while it was being given, and after it had been discontinued. Simultaneous tests were done on the blood of a person without any history or evidence of a gonococcal infection.

TREATMENT

With a few exceptions, discussed below, the only treatment prescribed was sulfanilamide and the forcing of fluids. Most of the patients continued at their daily occupations while under treatment. All were first given 4 gm of sulfanilamide daily in four divided doses. Sometimes the dose was reduced to 2 gm a day so as to determine the effect on the course of the disease, and on the bacteriolytic titer of the blood. The drug was administered for from ten days to three weeks. It was felt that it should be continued as long as evidence of the infection was still present.

RESULTS OF TREATMENT

The criteria for declaring a patient cured were the absence of gonococci in stained smears of pros-

tatic secretions, a complete cessation of the urethral discharge, clear urines by the two-glass method and a maximum of four leukocytes per oil immersion field in stained preparations of prostatic secretions. The prostatic secretions, obtained by massage, were examined on three occasions at intervals of several days. On this basis, there were 11 patients who were declared free of infection four to seven weeks after treatment with sulfanilamide had been instituted. Of considerable importance were the clinical observations in 10 of these patients. Within twenty-four hours after sulfanilamide therapy, organisms permanently disappeared from stained smears of urethral exudates. However, urethral discharges persisted for several days longer before disappearing. These patients were probably kept under observation longer than was necessary before declaring them cured, but we were apprehensive about starting prostatic massages too soon.

Of the remaining 10 patients, 7 could not be classified as cured because they stopped coming to the clinic before three successive prostatic massages could be done. When last seen, however, all were without urethral discharge or genitourinary symptoms. In this connection, it may be added that we experienced considerable difficulty in convincing many of our patients to continue attending the clinic after they had received sulfanilamide for a few days. Their genitourinary signs and symptoms were reduced almost to a minimum, and they saw no reason to return.

The 3 remaining patients were classified as definite therapeutic failures. Although the drug was administered for over three weeks, they had a persistent urethral discharge, with gonococci present in stained smears. After two to three days of treatment, the organisms disappeared from the urethral discharge for from two to eleven days, after which they again became evident. The possibility that the strains of these individuals were refractive to sulfanilamide is discussed below.

Of the 8 patients who had received treatment for their infections before appearing at the clinic, 6 had been given anterior urethral irrigations with potassium permanganate, without apparent effect. Following sulfanilamide therapy, 3 were classified as cures, 2 as doubtful and 1 as a failure. Another patient had been given a gonococcal vaccine subcutaneously and prostatic massages, without improvement. His infection cleared up with sulfanilamide medication. One patient had taken some unknown capsules by mouth without relief, and responded well to sulfanilamide.

Although no serious side effects were noted as a result of the drug, several of the patients felt uncomfortable. The commonest symptoms were headache, dizziness and nausea. Eleven patients

with gonococcal infection, since the action of bacteriolytics has been shown to be a major mechanism in rendering the blood stream free of organisms. For this reason, sulfanilamide should be a useful adjunct in treating patients with all types of gonococcal infection. It should be emphasized, however, that while a high bacteriolytic titer is an expression of humoral immunity, it cannot be correlated closely with local immunity. In this regard, Spink and Keefer¹¹ have shown that while the blood stream may be rendered free of gonococci by the introduction of immune horse serum organisms may still be present in prostatic secretions. This fact was also illustrated in the present study by the 3 patients classified as failures. The bactericidal power of the blood was elevated while sulfanilamide was being administered, but the urethral exudates persistently contained gonococci. It may be argued from these cases that although the bactericidal tests done against two strains of gonococci showed the drug to be effective, the actual strain harbored by the patient would not be affected by sulfanilamide. We answered this, in part, by bactericidal tests with the patients' blood, to which small amounts of sulfanilamide and suspensions of the patients' own organisms were added. Under these circumstances the blood killed the organisms in large numbers.

Attention should be called to the systemic reactions that patients have as a result of taking sulfanilamide. Although our patients experienced no serious results, a potential danger lurks in the indiscriminate use of this drug. Unfavorable reactions may be prevented by observing the patient closely while he is under treatment.

SUMMARY

1 Twenty-one men with acute gonococcal urethritis were treated with sulfanilamide. Eleven of the patients were declared cured from four to seven weeks after treatment was instituted. Seven

patients were classified as doubtful, while 3 were refractive to treatment.

2. The dose of sulfanilamide was 4 gm daily in divided doses for from ten days to three weeks. Side effects of the drug included nausea, headache, dizziness, cyanosis, fever and diarrhea.

3. Immune studies on the blood indicated that sulfanilamide does not affect the gonococcal complement-fixation test or serological tests for syphilis.

4. Sulfanilamide increased the bactericidal powers of the patients' bloods against two strains of gonococci. This increase was demonstrated only while the drug was being administered. Since this mechanism is important in clearing the blood stream of organisms, sulfanilamide should be a useful adjunct in the treatment of local gonococcal infections.

We are indebted to Miss Marjorie L. Jewell and Miss Eleanor M. Fleming for technical assistance.

clinic for seventeen days, and a test showed the titer approximately that of a normal control. It should be noted that although his blood had a high bacteriolytic titer, gonococci were persistently dem-

due to a number of variable factors not clear at present.

From the foregoing experimental observations, it has been shown that the administration of

Chart 2 The patient received 4 gm. of sulfanilamide for eighteen days with clinical improvement. The chart shows the rise in the bactericidal power of the patient's whole blood while the drug was being received with decrease after it was discontinued.

onstrated in the urethral discharge. This observation is commented upon below.

We endeavored to ascertain the dose of sulfanilamide that would result in a marked rise in the bacteriolytic titer. It was found on several occasions that 4 gm. a day maintained a high bacteriolytic level, but when the dose was reduced to 2 gm. a day the bactericidal power of the blood was considerably reduced. It became evident during our observations that the optimum dose for maintaining a high bacteriolytic titer was 4 gm. daily. This fact is of considerable importance in treating patients where the organisms have invaded the blood stream.

DISCUSSION

Our clinical observations appear to confirm the reports of Dees and Colston⁸ and Reuter⁹ that sulfanilamide is effective in the treatment of some patients with gonococcal urethritis. Of the 21 patients studied, 11 were probably cured, 7 had no urethral discharge but could not be proved as free from infection, and 3 failed to respond to treatment. The ultimate outcome of these patients will depend upon a continued follow-up study. While our clinical results are not so satisfactory as those reported by others, this may be

sulfanilamide results in an increase of the bactericidal power of the blood against the gonococcus. A high bacteriolytic titer is desirable in patients

Chart 3 The patient received 4 gm. of sulfanilamide for eight days, with only slight clinical improvement, but marked increase in the bactericidal power of the whole blood. The drug was discontinued for seventeen days, and the bactericidal power was found to be the same as the normal control.

blood-sugar level was normal. The urine remained normal, likewise the leukocyte count of the blood. The temperature was almost constant at 104 to 105°F, with a pulse rate of 130 to 150. Blood cultures were negative.

The purulent discharge from the thigh wound gradually diminished, and swelling and redness subsided, the diminution in local reaction being in contrast with the sustained pyrexia. The stuporous state continued but the patient gradually became somewhat more responsive

There are some changes to be seen in gross, such as an intense congestion of the meninges and diffuse pinkish-purple discoloration of the gray matter, which did not seem to be due altogether to the congestion. No gross hemorrhages are present. In material that has been fixed in 10 per cent formalin and sectioned, there is a well-defined and pale grayish zone from 1 to 2 mm. in diameter in the deep layers of the cortical gray matter. It is found in practically all parts of the cerebral cortex of both hemi-

Figure 1 Low power photograph of the tip of a gyrus in the anoxic area. In the deep layers of the gray matter (laminæ 5 and 6) bordering the white matter is seen a dark streak. This is the principal lesion and here nerve cells are destroyed and replaced by glial and mesodermal nuclei which are present in excessive numbers (Nissl stain 10X) Kindness of Dr C S Kubik

to painful stimuli and at times uttered a few random words. The depression of tendon reflexes, absence of plantar response and general flaccidity remained unchanged. Two blood transfusions served to increase the hemoglobin, but produced no other noticeable beneficial effect. On the 12th day after the last operation signs of pneumonia became evident, and next day the patient died without ever having regained consciousness.

Autopsy. The postmortem examination was unrestricted. The distal half of the right femur, including the epiphysis, was extensively infected. The epiphysis was separated, the periosteal proliferation was marked. The knee joint had become involved, but no undrained pus could be found. Bronchopneumonia of the right upper and lower lobes was present. The findings in the brain and spinal cord were studied by Dr Charles S. Kubik* and were described as follows:

This description² was published in the *New England Journal of Medicine* under Case Records of the Massachusetts General Hospital (No 18352). It is the first published account of such a lesion and is repeated here because it has been lost in the context in which it first appeared.

spheres. Well-defined lesions of the basal ganglia are not apparent to the naked eye.

On microscopic examination, the vessels of the pia arachnoid are congested. The subarachnoid space contains numerous red blood cells and a few endothelial cells. In the deep layers of the cortical gray matter and in the corpus striatum and the optic thalamus there are circumscribed lesions characterized by destruction of myelin, proliferation of glial elements and intense proliferation of blood vessels. Axis cylinders passing through the lesion are preserved but damaged. Ganglion cells are diminished in number, and those that remain exhibit degenerative changes.

In the cerebral cortex the lesion consists of a more or less continuous well-defined zone up to 2 mm. in width with a smooth inner and irregular outer margin, situated in the deep layers of the gray matter, the inner margin corresponding to the junction of the white and gray matter. Within the lesion practically all myelin is destroyed. There is extensive proliferation of microglia, with numer-

CEREBRAL ASPHYXIA DURING NITROUS-OXIDE AND OXYGEN ANESTHESIA

JOHN D STEWART, M.D.*

BOSTON

A HAZARD of general anesthesia which is specially marked in the use of nitrous-oxide and oxygen mixtures is cerebral hypoxemia. Such lack of oxygen may be followed immediately by death, or recovery may be partial or complete. The case to be described is presented, as one in which hypoxemia during nitrous-oxide and oxygen anesthesia and surgical operation was at least partly responsible for the development of unusual neuropsychiatric manifestations and peculiarly localized degenerative lesions in the brain. The case is of interest not only as illustrating a hazard of anesthesia, but because of its bearing on problems of physiology and neuropathology. The cases reported by Courville¹ and Lowenberg, Waggoner and Zbinden² are of similar importance.

CASE REPORT

The patient, B P (M G H. No. 320093), a 12 year-old American schoolgirl, entered the hospital complaining of pain and swelling in the region of the right knee. Her previous health had been excellent, and no serious illness was noted in the past history. Two weeks before admission the patient had fallen downstairs and injured her right knee, and 4 days later pain, swelling and redness appeared just above the knee. Her temperature became moderately elevated, and the family doctor prescribed bed rest and ice packs on the knee.

On admission there were the signs of moderate reaction to infection in a generally well-nourished and well-developed girl. Examination of the chest and abdomen showed no abnormality. The lower half of the right thigh was diffusely swollen, reddened and exquisitely tender, the signs being most marked in the popliteal space and over the lateral aspect of the femur. X-ray films showed separation of the lower femoral epiphysis with erosion of the epiphyseal surfaces. The rectal temperature was 102.2°F, the pulse rate 120, and the leukocyte count 14,500. The urine was normal. A diagnosis of osteomyelitis of the lower end of the femur with separation of the epiphysis was made.

Operation was performed under nitrous-oxide and oxygen anesthesia. The anesthesia lasted 40 minutes and was well taken, the patient's color being good throughout. A large abscess beneath the muscles lateral to the lower half of the femur was drained, and the metaphysis was drilled in several places. Following operation the leg and thigh were splinted and gentle skin traction was applied. Pus from the abscess contained *Staphylococcus aureus* in pure culture.

Fever continued after operation, and on the 5th day counter-drainage through the popliteal space was established. Nitrous-oxide and oxygen anesthesia was again used, and lasted 45 minutes without cyanosis.

During the following week there was only slight evidence of improvement, and low grade fever and leukocytosis continued. A mild anemia was demonstrated, the erythrocyte count being 3,600,000 and the hemoglobin 75 per cent (Tallqvist). X-ray films showed increasing destruction of the metaphysis and lower diaphysis of the femur, in view of which, together with general evidence of persistent infection, it was decided to lay open the bone more thoroughly.

In the third operation, 11 days after the first, nitrous-oxide and oxygen anesthesia was again used. A window was made by cutting away the cortex laterally in the lower end of the femur to drain the medulla. No tourniquet was used. Anesthesia lasted 42 minutes and proceeded without mishap, except that the anesthetist had difficulty in maintaining regular and even respiration, so that several times the blood in the wound was notably dark. As the dressing was being applied at the conclusion of the operation the anesthetist reported that the patient had stopped breathing. When examined she was deeply cyanotic, although the air passages seemed clear. The pulse was full and strong, the rate 140. The heartbeat was very strong, and the neck veins distended. The anal sphincters were relaxed. Artificial respiration was started instantly, and with administration of 95 per cent oxygen and 5 per cent carbon dioxide the patient's color changed to a healthy pink. After 2 minutes, evidence of returning respiratory activity appeared in the form of a slight gasp. The gasps slowly became more frequent, and at one time there was a single, feeble attempt to vomit. The pupils at first were widely dilated, but as the patient's color improved they contracted. The pulse rate continued around 140, the blood pressure was evenly maintained at 130/70. At the end of 30 minutes, artificial respiration, which was very effective by reason of the flexibility of the chest wall, could be safely discontinued. By this time breathing was regular and even, but there were no signs of returning consciousness.

Soon after being returned to the ward the patient began to exhibit aimless waving, choreiform movements of the arms, facial grimaces, with rolling of the eyes upward and outward, and alternate periods of excitation and quiet relaxation. At times the excitation and coarse thrashing movements of the arms coincided with a burst of increased respiratory activity, the breathing being deeper as well as faster. There was incontinence of urine and feces, and no sign of perception of surroundings was displayed. Large doses of sedatives were ineffective in keeping the patient quiet. After 48 hours of maniacal delirium, excitement gave place to stupor, which was marked by flaccidity of muscles of the trunk and extremities, absent tendon reflexes, insensibility to painful stimuli and incontinence. Only feeble efforts at swallowing could be provoked by inserting liquids into the patient's mouth. Respiration was somewhat irregular, rapid and shallow.

Lumbar punctures, done twice with an interval of 3 days between, showed slightly increased initial pressure—285 mm. of water the first time and 240 mm. the second, the patient being relaxed. The chemical findings in the fluid were normal, as was the cytology of the fluid. The

in the case here reported and in those of Courville¹ and Lowenberg et al.² However, the question of specificity of effect is again raised, and despite experimental work of Haggard,⁸ Haldane⁹ and Ford,¹⁰ we are unable to say beyond doubt whether the destruction of cells in the deeper layers of the cortex and in the basal ganglia is due to carbon monoxide, to other toxins in illuminating gas and automobile exhaust gas or to cerebral oxygen lack.

Gildea and Cobb,¹¹ in a study of the lesions and symptoms produced in animals, by temporary cerebral anemia found that focal areas of necrosis were consistently demonstrable in the cortex of cats surviving at least twenty-four hours. "Areas of devastation" were frequently present in the third and fourth laminae and occasionally extended into the fifth. These workers stated, however, that no one type of lesions could be said to be pathognomonic of cerebral anemia. Various neuromuscular disturbances, abnormalities of behavior and definite loss of intelligence followed the damage to the cortical cells in many animals. G. N. Stewart and his co-workers¹² produced cerebral hypoxemia in dogs by interrupting the cerebral circulation for periods of from three to eighty-one minutes under artificial respiration. In animals making only a partial recovery, disturbances of locomotion, paralysis, loss of sight and hearing and loss of general intelligence were noted.

The evidence presented by the present case of nitrous-oxide asphyxia and those of Courville and Lowenberg et al. may be taken with the reported cases of poisoning from illuminating gas and automobile exhaust gas, and the experimental data on cerebral anemia in animals, as suggesting that the common factor, cerebral hypoxemia, may result in destruction of cortical cells and survival of more resistant tissues, with consequent loss of intelligence and various disturbances at lower levels.

SUMMARY AND CONCLUSIONS

A case is reported in which apnea occurred during nitrous-oxide and oxygen anesthesia, causing widespread destruction of the nerve cells of the cerebrum. Neurologic symptoms appeared within an hour and lasted about forty-eight hours, when coma supervened. Death from pneumonia occurred on the thirteenth postoperative day. A review of the literature shows that this is not a rare sequence of events. Autopsy showed changes in the cerebral nerve cells similar to those found after experimental cerebral hypoxemia, and to those described in other cases of asphyxial death after nitrous-oxide and oxygen anesthesia and poisoning from illuminating gas and automobile exhaust gas.

Cyanosis and respiratory difficulty during nitrous-oxide and oxygen anesthesia may be a precursor of immediate cerebral damage. Death may follow several days or weeks later.

ous granular corpuscles containing fatty material and particles of myelin. Many large mitotic cells are observed. Glial cells with large clear nuclei and well stained ameboid cell bodies, probably astrocytes, also appear to be increased in number. While axis cylinders appear to be practically undiminished in number, many of them are swollen or have a beaded appearance, and most of them exhibit some degree of alteration. Ganglion cells within the lesion are diminished in number. Most of those that remain appear

neuropsychiatric manifestations followed asphyxia from nitrous-oxide and oxygen anesthesia, and describes 13 new cases, 9 with fatal outcome. Lowenberg, Waggoner and Zbinden² report 4 cases of a similar nature. In both reports the authors point out that the widespread irregular destruction of cortex and basal ganglia, such as that shown in the

Figure 2 Myelin sheath stain of the same lesion as that shown in Figure 1. Here the picture is reversed: the white matter looks black and the lesion looks light because of lack of myelinated nerve fibers, which can be seen both above and below it. (Spielmeier stain, 40 \times). Kindness of Dr. C. S. Kubik.

to be severely damaged, some are very pale, somewhat shrunken or swollen and vacuolated and have pale nuclei, others are shrunken, more deeply stained, and have small, deeply stained nuclei. Neurophagia is not observed. Outside the zone of severe degeneration ganglion cells are not normal, they are pale, no Nissl bodies are observed, and the cytoplasm has a homogeneous finely granular appearance. Some of them have shrunken, somewhat distorted and eccentric nuclei, which, however, have well defined nuclear membranes and are not deeply stained.

"There is congestion of the cortical blood vessels. In the zone of degeneration the capillaries are greatly increased in number and there is extensive proliferation of their cellular elements. No hemorrhages are observed.

Lesions of the nature described are found in sections of cortex taken from various parts of the brain, and essentially the same findings are present in the corpus striatum and the optic thalamus. They are not observed in tissues consisting purely of white matter, nor are they found in sections of the pons, the cerebellum, the dentate nucleus or the spinal cord.

COMMENT

In a detailed and comprehensive report Courville¹ discusses recorded cases in which unusual

present case and most of theirs, may conceivably represent either a specific toxic effect of nitrous oxide or the damage incident to oxygen lack in these sensitive tissues.

Many cases of varying degrees of poisoning from inhalation of automobile exhaust gas and illuminating gas have been reported in detail. Various neuropsychiatric sequelae, such as generalized hyper-tonus, choreiform movements, Parkinsonism, peripheral neuritis, deafness and blindness, acute psychoses and mental decline are recorded.^{4,5} The pathologic changes in the central nervous system include vascular thromboses and petechial hemorrhages, cellular degeneration, demyelination and glial proliferation. Many observers have noted the greater frequency of the lesions in the cortex and basal ganglia.^{4,6,7} The psychiatric and neurologic symptomatology in such surviving cases of partial recovery, as well as the type and localization of the cerebral lesion in cases of brief survival, bear a suggestive resemblance to the picture seen

The success obtained in this case has led to somewhat similar operations with patients who have sustained trauma, and in whom the addition of a

factorily useful thumb which appeared fairly normal (Fig 3)

PROGRESS IN THE STUDY OF CARDIOVASCULAR DISEASE IN 1936

SYLVESTER MCGINN, M.D.*

BOSTON

THE medical literature of 1936 contains the reports of many and varied investigations of the cardiovascular system. It is the purpose of this review to abstract most of the references related to the cardiovascular system, and to provide a bibliography illustrative of the persistent advance in our knowledge of heart disease. Most successful thus far has been the clinical approach to the problem, which has enabled us to make diagnoses and prognoses with a considerable degree of accuracy. To know the correct diagnosis and what the probable course will be is essential in the rational treatment of any illness. Studies of the etiology and treatment of diseases of the heart are being carried on by many able investigators, and eventually their research efforts will give us a more complete understanding of the disorders of the cardiovascular system.

The introduction of the chest lead to electrocardiography has presented certain problems that are gradually being worked out, namely, those re-

lating to the establishment of normal variations.

Rheumatic fever and arteriosclerosis are responsible for much of our heart disease, and many investigators are engaged in the study of these two conditions. A recently proposed therapeutic procedure intended to control hypertension is being carefully considered. The treatment of cardiovascular syphilis is ever a debatable question, and several papers in 1936 offer evidence supporting the need for adequate therapy.

Several new books by well-known cardiologists have been offered to those interested in the cardiovascular system. A number of these are designed for teaching, and are excellent for those who wish to know more about the disorders of the heart or to bring their knowledge up to date. Other works have been devoted to special subjects, and contain our most authoritative information concerning them.

Levine has published a very interesting and useful book, *Clinical Heart Disease*. It is written for the student and general practitioner, and adequate

BOSTON

WHEN an individual is injured in an accident and is taken to a hospital or a doctor's office, the usual procedure is to repair the damage as speedily as possible, even if it means the sacrifice of some viable tissue in order to bring skin edges together. This is particularly true of injuries to fingers. Nearly all surgeons feel that if a finger is cut cleanly across they will have to remove some bone in order to get proper flaps for a traumatic amputation. On the other hand, if at the first dressing every bit of viable tissue is saved, it can be decided at a later date, when it is known just what tissues have survived, what type of plastic operation to perform in order to obtain the best result.

The following case is reported because it seems to be a new procedure. Nowhere in the literature or through conversation with other surgeons has the writer encountered a similar operation.

On August 19, 1932, shortly after midnight, a young woman was brought into the Cambridge Hospital after being seriously hurt in an automobile accident. Although she said that she had lost consciousness at the time of the accident, she was quite herself at the time of admission. Aside from minor contusions, abrasions and lacerated wounds, the most important injuries were apparently the loss of the distal phalanges of the index and middle fingers of the right hand. The patient was a nurse who was finishing her training, and realized that if her fingers were shortened it would be a great handicap to her in finishing her course and carrying on her profession. Each finger had been cut completely across vertically to its axis through the distal interphalangeal joint. The skin and subcuticular tissues were slightly retracted from the joint cartilage and bone.

The patient was told that two procedures were possible: one to shorten the fingers considerably and obtain satisfactory flaps to close the wounds, the other, an untried method, to attempt to save all the tissue and restore the fingers to nearly their normal length. Although the latter method meant her being hospitalized for a time, she chose it.

An operation was done under ether anesthesia. The hand and right thigh were prepared. Minute pieces of bone and cartilage at the end of each injured finger were removed, so that no sharp points were left. Two ribbons of skin were separated from the outer and upper side of the thigh. With them was taken a substantial layer of subcuticular fat. Both ends of the ribbons were left attached so as to maintain the best possible circulation. The hand was then everted with the palm up, and one strip of skin was sewed to each finger stump (Fig 1). The hand was then solidly strapped to the thigh with adhesive plaster, the arm was bound to the side of the body, and sterile dressings were applied.

The patient made a good ether recovery, and during the subsequent days, although fairly uncomfortable because she had to keep her arm in the same position, did not suffer much pain. On August 26, 7 days after the operation, the strips were cut on either side of each finger, leaving a thick tab of tissue attached to the ends of the fingers. In both cases the circulation was excellent, the tabs viable and the wounds clean. The fingers were dressed with boric ointment, and the wounds in the thigh were closed with interrupted silkworm gut sutures, leaving

Figure 1 A diagrammatic drawing showing the patient's hand lying on the thigh with one strip wholly sewn and the other half attached to the injured fingers. The insert shows a finger after being cut away from the thigh.

two straight lines. The patient was then allowed to move about. As the fingers healed, they were strapped with sterile adhesive plaster so as to obtain the best possible shape.

On September 14, 4 weeks after the accident, the middle finger showed a small cleft near the tip. Lest this fold should interfere somewhat with function it was excised, using 1 per cent novocain as a local anesthetic, and the new skin edges were brought together. A week later both fingers were perfectly healed.

In October, the patient complained of having a growth of hair on the tips of the fingers. This hair soon wore off. Subsequently the patient returned to her work in a hospital, and has since had no trouble with the fingers. As the weeks passed into months, the new tabs gradually shrunk, leaving adequate non-tender coverings to the fingertips (Fig 2).

lating to the establishment of normal variations.

Rheumatic fever and arteriosclerosis are responsible for much of our heart disease, and many investigators are engaged in the study of these two conditions. A recently proposed therapeutic procedure intended to control hypertension is being carefully considered. The treatment of cardiovascular syphilis is ever a debatable question, and several papers in 1936 offer evidence supporting the need for adequate therapy.

Several new books by well-known cardiologists have been offered to those interested in the cardiovascular system. A number of these are designed for teaching, and are excellent for those who wish to know more about the disorders of the heart or to bring their knowledge up to date. Other works have been devoted to special subjects, and contain our most authoritative information concerning them.

Levine has published a very interesting and useful book, *Clinical Heart Disease*. It is written for the student and general practitioner, and adequate-

ly discusses the diagnosis, prognosis and treatment of heart disease

Herrmann presents a concise text on the cardiovascular system, also designed for practitioners and students, entitled *Synopsis of Diseases of the Heart and Arteries*. It is well written and amply illustrated. One third of the book is devoted to methods of examination, and the remainder to a discussion of the diagnosis and treatment of the various cardiac disorders. The final chapter concerns diseases of the peripheral vascular system.

Lutembacher, the well-known French clinician, correlates clinical studies and interpretations with anatomical findings of the heart in his book *Les Lésions Organiques du Cœur. Étude clinique, anatomique et thérapeutique*. There are many photographs of pathological specimens, which are described in the text.

Levy has edited a work entitled *Diseases of the Coronary Arteries and Cardiac Pain*. His collaborators include some of the foremost men interested in the circulation. It deals with all aspects of the coronary circulation and coronary heart disease. The book embodies our present knowledge of this subject, and shows the extent to which we have gone in treating it.

Abbott, in the *Atlas of Congenital Heart Disease* summarizes her vast experience over years of painstaking observation of congenital defects of the heart. This is the most complete and most up-to-date work on the subject, it is based on 1000 cases. There are many illustrations. Part I comprises a description of the development and comparative anatomy of the heart. Part II consists of a clinical classification of congenital heart disease arranged by groups, acyanotic, cyanotic tardive and cyanotic.

The Clinical Use of Digitalis has been produced by Luten. It presents a complete discussion of the valuable drug digitalis. Sixty-four pages are devoted to dosage and methods of administration.

Gradually data are being assembled that give us a definite picture of the geographic distribution of heart disease. It is of the greatest importance that such information be available to those investigating the etiology of various diseases of the cardiovascular system, so that they may be able to recognize the environmental factors most favorable or most unfavorable to a particular disease. It is of interest to note the occurrence of cardiac disease in New Zealand, as observed by Robertson in a survey of 700 consecutive patients with heart disease. The incidence of the various etiologic factors in 90 per cent of the cases was as follows: arteriosclerosis 32 per cent, cardiac neurosis 21 per cent, hypertension 14 per cent, rheumatic fever 14 per cent and thyrotoxicosis 12 per cent.

Geiger and his associates studied 3535 cardiac

cases representing a cross-section of the population of San Francisco. In 1933 the standardized death rate from heart disease per 100,000 population was 271.26. The degenerative diseases and arteriosclerotic hypertensive heart disease comprised 46.4 per cent of the total cases, rheumatic heart disease 22.2 per cent, syphilis 7.2 per cent, and congenital heart disease 5.5 per cent.

PHYSIOLOGY

Fineberg and Wiggers report their important experiments on dogs, in which they observed the reaction of the right ventricle to increasing gradual compression of the pulmonary artery. The aortic pressures and right intraventricular pressures were simultaneously recorded with optical manometers. With compression of the pulmonary artery up to 58 per cent, changes within the right ventricle are sufficient to overcome the pulmonary resistance, so that the blood supply to the left ventricle is unimpaired and the arterial pressure is but little affected. With increased pulmonary compression, however, the continued stretch of the right ventricle leads to beginning failure, especially with diminished coronary flow subsequent to a lowered arterial pressure. These authors feel certain that circulatory failure after obstruction of the pulmonary artery is due solely to fatigue of the right ventricle. Clinically, they believe, in such cases arterial pressure must be maintained so as to provide adequate coronary circulation to the failing ventricle. This implies that drugs directed toward lowering the pressure, as well as venesection, may be harmful and should be avoided. Lead 2 of the electrocardiogram was made on the dogs, and showed failure of the sinus mechanism, which was replaced by A-V nodal rhythm, followed either by cardiac asystole or ventricular fibrillation.

Dieckhoff in two papers discusses the capacity for work of the hearts of normal cats and of those with artificially produced aortic insufficiency, with and without hypertrophy. The capacity was tested first by increasing arterial pressure, secondly, by increasing cardiac output through raising the venous pressure, and thirdly, by noting the duration of life of the heart-lung preparation. The hearts with recently injured aortic valves and without hypertrophy showed by all three tests diminished capacity for work as compared with the normal or hypertrophied hearts. When a rubber valve was substituted for the damaged aortic valve, it was found that the recently damaged hearts compared favorably with the normal ones, but that the hypertrophied hearts continued to function longer than did the normal ones, this indicated the pronounced capacity for work when hypertrophy is present. It was found that digitalization before

injury to the aortic valve resulted in a greater ability to work than was shown by the undigitalized animals, although it was less in cats with normal hearts. Digitoxin and strophanthin were injected into the same types of hearts, both in the intact animal and in the heart-lung preparation. It was found that the lethal dose was diminished by 22 to 47 per cent when hypertrophy occurred.

The blood flow in the circumflex branch of the left coronary arteries in dogs has been studied by Essex and his associates with the *Thermostromuhr* of Rein. Epinephrine caused a transient increase in coronary blood flow four times that of control values, with nitroglycerin or amyl nitrite the flow was doubled for a short time. After injection of thyroxin the increase of flow was 244 per cent over the control value, and the increase persisted for forty-eight to ninety-six hours after injection. No significant correlation between coronary flow and heart weight or pulse rate was observed.

Brouha, Cannon and Dill studied the heart rates of totally sympathectomized dogs. The cardiac rate at rest was less than normal, and after exercise the acceleration was 30 to 40 per cent below normal. The dogs' capacity for work was not diminished. It was thought that cardiac acceleration in dogs after sympathectomy was due to lessened tonicity of the cardioinhibitors of the vagi and to an increase in the tonicity of the vagal cardioaccelerators.

Bradshaw reports his observations of the fall in blood pressure in 5 healthy and 4 completely sympathectomized cats. In the latter group the blood pressure fell very little after the spinal injection of procain, but in the healthy animals the fall was considerable. It was attributed to paralysis of the vasoconstrictor nerve fibers, especially those below the fifth thoracic level.

Barsoum and Smirk found in cases of congestive failure that there is an increase in the concentration of histamine-yielding substances in whole blood, entirely due to greater concentration within the red cells. Concentrations of these substances in the plasma and serum transudates, such as ascites and edema fluids, are equal and are within normal limits. In view of this fact the authors think that the presence of an excess of histamine-yielding substances in the whole blood does not explain an increased permeability of the capillaries in congestive failure.

PATHOLOGY

Gross and Fried examined the Tawara node and bundle of His of hearts from 110 patients, 60 of whom had active rheumatic fever, 25 inactive rheumatic fever, and 25 nonrheumatic conditions. Inflammatory and vascular changes were found in 66

per cent of the active cases, even though complete serial sections were not examined. The inactive cases showed few changes. Very few of the lesions seen were of a specific or highly characteristic nature.

Gross and Friedberg studied the cardiac valve rings of 40 nonrheumatic and 97 rheumatic hearts. The valve rings were selected for study because of the common belief that inflammation spreads from them to the valves and surrounding tissue. Normal rings rarely showed capillaries or inflammatory cells, but the valve rings of the rheumatic group showed extensive changes consisting of infiltration of inflammatory cells, vascularization, edema and scarring. Usually all rings were affected, but the pulmonic ring was the one oftenest free of change.

These men also studied a group of cases which at postmortem examination showed indeterminate terminal, or thrombotic, endocarditis. They believe that nonbacterial thrombotic endocarditis is an accidental occurrence in the course of a fatal disease, has no clinical significance, and probably develops on previously damaged valves. In two subsequent papers in collaboration with Friedberg and Wallack, Gross discussed two groups of nonbacterial endocarditis as found in acute thrombocytopenic purpura and in cases with prolonged fever, arthritis, inflammation of serous membranes, and widespread vascular lesions.

Thompson and White found 704 cases of right ventricular hypertrophy among 2000 consecutive autopsies wherein the wall was greater than 5 mm in thickness. In nearly 25 per cent of the cases no cause for strain on either ventricle was found. In 61 per cent of the remaining cases the strain on the heart had been due to hypertension, aortic-valve disease or infarcts in the left ventricle, and no cause for primary strain on the right ventricle could be discovered. Right ventricular hypertrophy was found in pure cases of left ventricular strain, with or without clinical evidence of failure, but when congestive failure was present the degree of right ventricular hypertrophy was greater.

Parkinson chose as his subject for the Lumsden Lecture of 1936 in London a discussion of our present knowledge of the size of the heart and the factors influencing it.

Andrus studied the structure of the small arteries and arterioles of the pectoral muscles of hypertensive and nonhypertensive patients. In the former group, it was noted that the fibrosis of the media of the small arteries and arterioles was somewhat more pronounced than that of nonhypertensive patients. Not all hypertensive patients, however, showed marked fibrosis. Prior to the twenty-ninth year no such cases were seen, but

they were encountered with increasing frequency after that age

Peery reports 5 cases found at autopsy to have dissecting aneurysms which were unrecognized before death. All the cases were those of Negroes, varying from twenty-two to forty-six years in age, 3 of whom had recognized hypertension. One had cardiovascular syphilis. One patient lived for about fifteen months after the clinical episode assumed to represent the rupture of the aorta.

ETIOLOGY

Congenital

The subject of congenital heart disease is reviewed by McGinn and White. They find the incidence to be about 1 per cent in 7500 autopsies. Their statistics indicate that the correct diagnosis is being made much more frequently in recent years than ever before. Ten of the congenital lesions that could be accurately diagnosed are discussed, with co-ordination of symptoms and signs of roentgenographic and electrocardiographic evidence.

Yater describes a very interesting but uncommon condition of congenital origin known as Chiari's network. It consists of a reticulum of coarse or fine fibers attached to the interatrial septum at one end and to the eustachian and thebesian valves in the right auricle at the other end. Its clinical importance is paradoxical in that emboli originating in the periphery may become enmeshed in its fibers and so held in the right auricle, where they may become broken into smaller particles. On the other hand, thrombi may form within the meshes themselves and be a source of pulmonary emboli. In Yater's case, an embolus 11.5 cm long, probably originating in a femoral thrombosis, was caught in the mesh of Chiari's network, from which point small emboli caused pulmonary infarction. The right auricle and ventricle were hypertrophied. Chiari's network causes no symptoms or signs, but should be considered as a possibility when multiple pulmonary emboli are encountered.

Taussig reports an interesting congenital defect of the heart in which the right ventricle failed to function, as a result of which the tricuspid and pulmonary valves became atresic. The escape of blood took place through the interauricular septum. If a competent patency exists, the heart functions as a two-chambered organ, otherwise as a three-chambered one—as biloculate or triloculate. Pulsation of the liver edge is easily felt when the septum between the auricles is intact and this aids one in determining whether the heart is functioning as a triloculate or biloculate organ. Clinically, persistent cyanosis and absence of murmurs are found in the anomalous case in

which the right ventricle fails to function. The electrocardiogram shows left-axis deviation, and the x-ray shows a concavity of the left heart border due to the absence of the pulmonary conus.

Arkin describes 6 cases, 2 with autopsy, of congenital heart disease characterized by a persistent right aortic arch and a rudimentary left aortic arch. The aorta in these cases passes upward to the right of the sternum and crosses to the left behind the trachea and the esophagus. The x-ray in the anterior view gives evidence of the aorta to the right of the sternum and absence of the usual aortic knob on the left. In the oblique or lateral view, the barium-filled esophagus is displaced forward as it passes over the transverse portion of the aorta.

Kissin found in the literature 154 cases of pulmonary valves with a supernumerary cusp, or four cusps, 3 of which were known to have shown pulmonary regurgitation. He reports a case with evidence of pulmonary regurgitation which showed enlargement of the pulmonary conus.

Subacute Bacterial Endocarditis

Segal reviews the literature in order to determine the incidence of the cardiac arrhythmias in bacterial endocarditis, in addition to reviewing a series of 192 cases of bacterial endocarditis, 67 of which had electrocardiograms. He found 4 cases of auricular fibrillation in that series, 2 of auricular flutter, and 12 of various types of heart block.

Rheumatic Heart Disease

Werner studied 100 cases of rheumatic heart disease with heart failure, 75 necropsies of the same condition and 50 cases of cardiovascular syphilis. Evidence of active rheumatic infection was demonstrated in 45 per cent of the clinical cases, and was suspected in an additional 21 per cent. Activity of the infectious process was found in 66 per cent of the necropsy specimens.

Coburn finds that the antistreptolysin curves of rheumatic fever differed from those of other streptococcal infections. The difference lies in the delay of the immune response in rheumatic fever and the delay in the elimination of products of hemolytic streptococci, as indicated by the persistence of high antistreptolysin titer levels for months after the infection. Coburn observed that the sedimentation rate is most rapid early in the course of acute rheumatic fever. The titer of antibody to hemolytic streptococcus does not attain its maximal level until the symptoms are regressing. This relation persists whether or not the acute attack was the initial one and whether or not it was a recrudescence. When there is no antistreptolysin response the patient is found to be free of symptoms and the sedimentation rate is normal.

Further evidence that an elevated sedimentation

rate is a measure of the extent of rheumatic activity is noted by Coburn and Kapp. It is believed to be due to an increase in plasma fibrinogen and globulin.

Sendroy and Schultz describe improvements in the urinary excretion test for ascorbic acid on a quantitative basis. Through digestive disturbances, rheumatic fever patients may develop a hypovitaminosis, with possible depletion of ascorbic acid and other vitamins, even though on an adequate diet. It is thought that ascorbic acid deficiency is a result and not the cause of the rheumatic infection. In a further clinical study, Schultz compared two groups of rheumatic children, one of which had received daily doses of ascorbic acid. In the treated group, subclinical scurvy was avoided, as determined by tests of capillary permeability. Neither the incidence nor the clinical course of acute rheumatic fever was demonstrably affected by the administration of ascorbic acid orally or intravenously. Schultz concluded that the deficiency of ascorbic acid was not a necessary factor in the etiology of rheumatic fever.

Rinehart, in a symposium on rheumatic fever, states that guinea pigs develop heart and joint lesions comparable to those of rheumatic fever when they have had a deficiency of vitamin C and an infection has been present. In the experimental work, no sharp line could be drawn between the picture of rheumatic fever and that of rheumatoid arthritis. Knowledge of the metabolism of vitamin C is far from complete, but it may eventually help to explain the etiology of rheumatic disease.

Dawson and Tyson comment on the relation between rheumatic fever and rheumatoid arthritis, and suggest that one may be a continuation of the other, the phase depending on age or on susceptibility of the host. Pathological evidence suggests that the two conditions represent different responses to the same or similar etiologic agent, whatever it may be. Even though *Streptococcus hemolyticus* is thought to play a role in the production of both diseases, the evidence is far from being complete, and even then it will probably be insufficient to explain the relation.

Angina Pectoris

Experimental evidence has been reported by Jackson and Jackson to support their theory that our concept of angina pectoris as due to coronary artery spasm is erroneous. Electrical stimulation at various parts of the esophagus resulted in pain similar in distribution to that of angina pectoris. They believe that angina pectoris is the result of spasmodic contractions of the esophagus and stomach, so that gas and materials contained with-

in these organs exert pressure on the walls of the viscera, causing strain and injury.

Bullrich employed cobra venom because of its analgesic properties in the treatment of 10 patients with angina pectoris. It was given intravenously every other day until the cessation of symptoms permitted its less frequent use. In all cases, pain was decreased and the capacity for work was increased.

Coronary Disease and Coronary Thrombosis

Johnston studied the incidence of coronary sclerosis in Negroes and Whites in North Carolina. In 400 autopsies the incidence of marked coronary sclerosis for white males was 24 per cent, for colored males 9 per cent, for white females 10 per cent, and for colored females 4 per cent.

Willius examined 370 cases of coronary thrombosis, 72 per cent of which occurred between fifty and seventy years of age. The ratio of men to women was 7:1, with cardiac death rates of 50 and 63 per cent respectively. Over half the patients died of cardiac deaths, and 45.7 per cent of them were reported as living. Of the cardiac deaths, 36.6 per cent were due to coronary thrombosis, 51.9 per cent to gradual myocardial failure and 11.5 per cent to an undetermined cause. The cardiac death rate increased progressively with recurrent attacks: 47.5 per cent with solitary occlusions, 69.8 per cent with two occlusions, and 75 per cent with three occlusions. Of the surviving patients 42.6 per cent reported themselves in good health, 23.1 per cent as well with restricted activity, 28.9 per cent as with recurrent anginal attacks, 3.6 per cent as with congestive failure, and 1.8 per cent as having suffered cerebrovascular accidents.

Two hundred and forty-three patients suffering from 267 attacks of coronary thrombosis are reported by Master, Jaffe and Dack. All were treated solely by bed rest and a low-calorie diet. The mortality rate was 16.5 per cent, in 8 per cent the fatal attack was the first. The ratio of women to men was 1:3, and most of the patients had an associated hypertension or diabetes, with occlusions occurring not infrequently in the fourth and fifth decades.

A study of 242 patients whose coronary arteries were found at postmortem to be sclerotic was made by Polanco. About two thirds of the patients were males. Cardiac pain had been present in 14.9 per cent, all of whom had moderate to marked sclerosis. In no cases with mild sclerosis was there a history of pain. The ratio of heart weight to body weight was increased in about 90 per cent of the cases.

Of 45 cases of Adams-Stokes' syndrome,

Schwartz reports 15 that followed an acute coronary occlusion. Of these, 7 lived for an average of twenty-six months with alternating transient or complete auriculoventricular dissociation, and 4 were reported as living with normal sinus rhythm. Four patients died within four days, the rhythm returning to normal in 2 cases. The treatment of such patients should include shock therapy, intramuscular injections of adrenalin and the daily administration of ephedrine sulfate. The results in these cases warranted the use of adrenalin despite the presence of coronary disease.

A case of thromboangitis obliterans is reported by Saphir in which the patient, a man of thirty-five, died suddenly. Autopsy revealed severe thromboangitis obliterans and arteriosclerosis of the coronary arteries, with small myocardial infarcts.

Levy and Bruenn report 24 cases in which there was sudden death and no fresh thrombus was found in the coronary vessels. They term this condition "acute, fatal coronary insufficiency."

A low-calorie diet (800 calories) was fed to 28 patients with coronary thrombosis and to 14 patients with angina pectoris by Master and his associates. In 31 patients the metabolism dropped from 15 to 35 per cent, in 6 from 10 to 14 per cent, and in 5 less than 10 per cent. The associated weight loss averaged 6 per cent of the initial weight. It required two to four weeks for the metabolism to drop, and an equal time for it to be re-established with a normal diet. No ill-effects from the low metabolism were observed in three to twelve months of undernutrition. Master believes that the low basal metabolism has a beneficial effect on the cardiovascular system, and that often the symptoms of heart disease are alleviated.

Cardiovascular Syphilis

In a series of papers on cardiovascular syphilis Cole and Usilton first consider syphilitic aortitis. They found 326 cases of uncomplicated syphilitic aortitis, representing 4.9 per cent of their total admissions for latent syphilis. The Wassermann reaction was positive in 72 per cent and the spinal fluid was abnormal in 49 per cent. Of patients adequately treated after the discovery of syphilitic aortitis, 63 per cent were living and free of symptoms, as compared with 49 per cent of those inadequately treated. Better results were noted when small doses of arsenicals were administered.

In their second paper, Cole and Usilton analyzed 260 cases of cardiovascular syphilis, 69 per cent of which had had no previous therapy. The incidence was three times as great in negro men as it was in white men, and was found to occur most frequently twenty to thirty years after the initial infection. The Wassermann test was positive in 85 per cent

and 62 per cent of the spinal fluid studies showed abnormalities. The use of adequate amounts of both arsenicals and heavy metals was found beneficial to patients with syphilitic aortic regurgitation.

Seventy-four cases of aneurysm were studied by Cole and Usilton. One third of these showed involvement of the central nervous system. Seventy-seven per cent of the patients had had no previous treatment. The Wassermann reaction was positive in 90 per cent of the cases, and 64 per cent of the spinal fluids examined were abnormal. Symptomatic relief was obtained in 56 per cent of the cases, the patients receiving more than thirteen arsenical injections, heavy metals being prescribed in the interim. The average duration of life after detection of the aneurysm, when adequate treatment was administered, was 75 months, 16 per cent of the cases being followed for eight years or more.

Hypertension

Schulze and Schwab give an interesting discussion of hypertension in the Negro. Essential hypertension is very rare in the African Negroes, whereas their descendants, the American Negroes, have two and a half times as much hypertensive heart disease as do the Whites. The incidence is one and a half times as great for women as for men. Schulze and Schwab attribute the apparent differences between African and American Negroes to the fact that the latter have tried to adopt the mode of life of their new-found civilization, but only with restraint and many tribulations. They deprecate the theory of the biologic inheritance of primary hypertension in view of this variation in the same race.

Following a study of 40 cases of heart failure in hypertension, Averbuck concludes that an associated coronary sclerosis or thrombosis is responsible in a great majority of cases (85 per cent). In a control group of 30 patients with hypertension, but dying of cerebral accidents or incidental disease and without congestive failure, only 10 per cent showed significant coronary disease.

Marañón and Domenech conclude from their studies of the blood pressure that it is not influenced by changes in the secretions of the hypophysis. Such variations as were noted were thought to be normal changes, implying a relation to increasing age. Hypertension associated with bromophilic adenoma of the hypophysis was believed to be secondary to hyperplastic changes in the suprarenal rather than in the hypophyseal gland.

Palmer reviewed 169 cases of hypertension in order to determine the success of medical measures, to discover what might be expected from surgical procedures, and to ascertain which types

were most apt to be benefited. Of patients under thirty-six years of age with variable systolic pressures up to 180 mm., 75 per cent will, he believes, have a normal pressure within ten years. Patients in later life with elevated systolic but nearly normal diastolic pressures, due to large-vessel sclerosis, are known to do well. With ample medical care, a substantial fall in systolic pressure occurs in one half of the mild and moderate and in one third of the severe cases of essential hypertension. Symptomatic relief is obtained in 90 per cent of the mild cases, 75 per cent of the moderate, and 46 per cent of the severe. Palmer believes that surgery may be indicated in certain patients of the mild or moderate groups and in young adults who show rapid progress of the hypertension. He hopes that splanchnic resection will give lasting symptomatic relief and halt the progress of the disease.

Hines and Brown devised a test consisting of recording blood pressure readings before and after immersion of a hand in ice water, so as to measure generalized vasomotor tonus. Observed responses are classified as normal, intermediate or abnormal. Ninety-eight per cent of the cases with essential hypertension had maximal abnormal reactions. Three cases of the intermediate or prehypertensive group developed hypertension. This suggests that the test may be useful in determining which cases may eventually develop essential hypertension.

Findlay describes several of the surgical procedures devised for the treatment of high blood pressure, and comments on the probable results in such operations.

Pulmonary Heart Disease

Oppenheimer and Hitzig studied the hemodynamics of pulmonary and myocardial insufficiency in chronic lung disease. Their investigation included measurement of the initial venous pressure, and that exerted during right upper-quadrant compression, arm-to-lung time, arm-to-tongue time and lung-to-tongue time. The circulatory measurements are normal in pulmonary insufficiency, owing to emphysema, and abnormalities indicate that the condition is complicated by myocardial failure. If the latter is present it may be due to failure of the right heart consequent upon the lung disease, or to left-heart failure resulting from a coexisting cardiovascular disease. Right-heart failure is characterized by high venous pressure, increased further by upper abdominal pressure, by prolongation of the arm-to-lung time and by an almost normal lung-to-tongue time. Left-heart failure shows a normal initial venous pressure, with or without a rise with right upper-quadrant compression, and an almost normal arm-to-lung

time. In bronchial asthma the measurements are normal, but in cardiac asthma there is a prolongation of the lung-to-tongue time. In chronic bronchopulmonary disease there seems to be no parallelism between the severity of the symptoms and retardation of the circulation through the lungs.

From their clinical and experimental study of emphysema, Kountz, Alexander and Prinzmetal have made these observations: (1) the heart is affected in most patients with emphysema, (2) cardiac hypertrophy with dilatation of the right ventricle may give symptoms in the late but not in the early stages, (3) coexisting left ventricular hypertrophy, in the absence of its obvious causes, is unexplained, and (4) from experimental work done on dogs, hypertrophy and dilatation seem to occur in the earlier stages of emphysema when the lungs are in the process of distention. In dogs with partial tracheal obstruction, the intrapleural pressure and peripheral venous pressure fall as the lungs distend. When complete distention is attained, intrapleural and finally venous pressures rise, resulting in less blood entering the heart and a consequent fall in right auricular pressure.

Darley and Doan report a case of primary pulmonary arteriosclerosis. It occurred in a twenty-year-old woman who had had symptoms of pulmonary obstruction since childhood. She had used enormous quantities of salt all her life. Autopsy showed pulmonary arteriolar sclerosis, dilatation of the pulmonary artery and right ventricular hypertrophy. No cause for pulmonary hypertension other than the pulmonary sclerosis could be found.

Steinberg and Mundy injected many small emboli into the pulmonary arterial system of a dog, and found that 79 per cent of the total lung by weight could be deprived of its arterial circulation without causing death. After two or three weeks, restoration of blood supply in the damaged lung tissue became apparent as canalization and newly branching arteries appeared. Bronchial arteries are seen to become dilated, and it is suggested that a collateral circulation from these prevents actual necrosis of the lung tissue. Langendorf and Pick report the electrocardiographic changes observed in 4 patients showing lung emboli at autopsy. Most of the changes resembled a posterior infarct.

Miscellaneous

Weiss and Wilkins describe cardiac disturbances resulting from vitamin-B deficiency. They have observed tachycardia, bradycardia, asystole and syncope, right- and left-sided heart failure and collapse. In the electrocardiogram, T-wave changes

Schwartz reports 15 that followed an acute coronary occlusion. Of these, 7 lived for an average of twenty-six months with alternating transient or complete auriculoventricular dissociation, and 4 were reported as living with normal sinus rhythm. Four patients died within four days, the rhythm returning to normal in 2 cases. The treatment of such patients should include shock therapy, intramuscular injections of adrenalin and the daily administration of ephedrine sulfate. The results in these cases warranted the use of adrenalin despite the presence of coronary disease.

A case of thromboangitis obliterans is reported by Saphir in which the patient, a man of thirty-five, died suddenly. Autopsy revealed severe thromboangitis obliterans and arteriosclerosis of the coronary arteries, with small myocardial infarcts.

Levy and Bruenn report 24 cases in which there was sudden death and no fresh thrombus was found in the coronary vessels. They term this condition "acute, fatal coronary insufficiency."

A low-calorie diet (800 calories) was fed to 28 patients with coronary thrombosis and to 14 patients with angina pectoris by Master and his associates. In 31 patients the metabolism dropped from 15 to 35 per cent, in 6 from 10 to 14 per cent, and in 5 less than 10 per cent. The associated weight loss averaged 6 per cent of the initial weight. It required two to four weeks for the metabolism to drop, and an equal time for it to be re-established with a normal diet. No ill-effects from the low metabolism were observed in three to twelve months of undernutrition. Master believes that the low basal metabolism has a beneficial effect on the cardiovascular system, and that often the symptoms of heart disease are alleviated.

Cardiovascular Syphilis

In a series of papers on cardiovascular syphilis Cole and Usilton first consider syphilitic aortitis. They found 326 cases of uncomplicated syphilitic aortitis, representing 4.9 per cent of their total admissions for latent syphilis. The Wassermann reaction was positive in 72 per cent and the spinal fluid was abnormal in 49 per cent. Of patients adequately treated after the discovery of syphilitic aortitis, 63 per cent were living and free of symptoms, as compared with 49 per cent of those inadequately treated. Better results were noted when small doses of arsenicals were administered.

In their second paper, Cole and Usilton analyzed 260 cases of cardiovascular syphilis, 69 per cent of which had had no previous therapy. The incidence was three times as great in negro men as it was in white men, and was found to occur most frequently twenty to thirty years after the initial infection. The Wassermann test was positive in 85 per cent

and 62 per cent of the spinal fluid studies showed abnormalities. The use of adequate amounts of both arsenicals and heavy metals was found beneficial to patients with syphilitic aortic regurgitation.

Seventy-four cases of aneurysm were studied by Cole and Usilton. One third of these showed involvement of the central nervous system. Seventy-seven per cent of the patients had had no previous treatment. The Wassermann reaction was positive in 90 per cent of the cases, and 64 per cent of the spinal fluids examined were abnormal. Symptomatic relief was obtained in 56 per cent of the cases, the patients receiving more than thirteen arsenical injections, heavy metals being prescribed in the interim. The average duration of life after detection of the aneurysm, when adequate treatment was administered, was 75 months, 16 per cent of the cases being followed for eight years or more.

Hypertension

Schulze and Schwab give an interesting discussion of hypertension in the Negro. Essential hypertension is very rare in the African Negroes, whereas their descendants, the American Negroes, have two and a half times as much hypertensive heart disease as do the Whites. The incidence is one and a half times as great for women as for men. Schulze and Schwab attribute the apparent differences between African and American Negroes to the fact that the latter have tried to adopt the mode of life of their new-found civilization, but only with restraint and many tribulations. They deprecate the theory of the biologic inheritance of primary hypertension in view of this variation in the same race.

Following a study of 40 cases of heart failure in hypertension, Averbuck concludes that an associated coronary sclerosis or thrombosis is responsible in a great majority of cases (85 per cent). In a control group of 30 patients with hypertension, but dying of cerebral accidents or incidental disease and without congestive failure, only 10 per cent showed significant coronary disease.

Marañón and Domenech conclude from their studies of the blood pressure that it is not influenced by changes in the secretions of the hypophysis. Such variations as were noted were thought to be normal changes, implying a relation to increasing age. Hypertension associated with basophilic adenoma of the hypophysis was believed to be secondary to hyperplastic changes in the suprarenal rather than in the hypophyseal gland.

Palmer reviewed 169 cases of hypertension in order to determine the success of medical measures, to discover what might be expected from surgical procedures, and to ascertain which types

still of the ventricles, then a progressive increase in the heart rate up to 160 beats per minute before restoration of the basic ventricular rhythm. He describes the clinical appearance of the patients during the changes.

Sappington and Cook believe that atherosclerosis of the radial artery is extremely rare and gives no true indication of visceral sclerosis. It had been thought that age changes and arteriosclerotic changes were maximal in the coronary arteries.

Morlock and Horton failed to find any constant increase in the blood pressures of patients with renal tumors, nor did any consistent variation in blood pressure result from their removal.

Wood studied the sedimentation rates of 164 cases of heart disease. He found sedimentation slow in cases of congestive heart failure and of congenital heart disease associated with cyanosis. It was rapid in cases of active rheumatic carditis, syphilitic aortitis, myocardial infarction, bacterial endocarditis, malignant hypertension and angina that came on during rest.

Shookhoff and his associates found that the sedimentation rate in cases of acute coronary occlusion might be abnormal even though the white count and temperature have returned to normal limits.

X-RAY

Schwedel and Epstein demonstrate and explain the appearance of the pulmonary artery in roentgenograms.

Marks describes a proved case of calcification of the annulus fibrosis of the mitral valve, correctly diagnosed by x-ray during life. It can be detected by fluoroscopy, the instrument being focused on the left auriculoventricular groove and being shifted inward and downward at an angle of forty-five degrees.

Kommerell describes 10 cases with calcified heart valves, and the technic employed to demonstrate them.

Yater explains his technic for injecting interarterially a radio-opaque material by means of which the arterial system can be studied, and cites cases to demonstrate the value of this procedure. The material injected is Thorotrast, a stabilized 25 per cent colloidal solution of thorium dioxide. Yater has had no unfavorable experience with this drug. Roentgenograms made immediately after its injection show peripheral arterial abnormalities such as obliterative endarteritis, thromboangitis obliterans, embolism and arteriovenous aneurysms.

ELECTROCARDIOGRAPHY

Fenichel and his associates report further studies of the RS-T segment of the electrocardiogram following their experiments on cats. They conclude

from their observations that the area of necrotic myocardium resulting from a coronary occlusion is electrically inert, or produces only an initial current of injury in the electrocardiogram. However, the necrotic area is surrounded by a transitional area of myocardium which although not destroyed has nevertheless been damaged owing to an insufficient blood supply. These investigators believe that this transitional zone of temporarily damaged muscle is responsible for the "coronary" type of T wave, because of a delay in the process of retreat from the contractile to the resting phase of the muscle. The T wave sometimes becomes upright after coronary thrombosis, as the process of healing goes on and an adequate blood supply restores the muscle immediately surrounding the necrotic area to good function.

Fenichel, Shookhoff and Abramson have published their experiments on cats' hearts. They stimulated various parts of the ventricles and thereby produced extrasystoles in the electrocardiogram. At the same sites they cauterized areas of the myocardium, causing displacements of the RS-T segments. It was found that the phase of the RS-T segment was consistently opposite the direction of the initial deflection of the extrasystoles caused by stimulation of the same area of myocardium.

Harris and Hussey studied the serial electrocardiograms of 50 dogs before and after ligation of the anterior descending branch of the left coronary artery. Changes in the R-T segment in most cases were noted within two hours of ligation. Arrhythmias were common, 15 dogs developing ventricular fibrillation immediately or within ten minutes after ligation. Eighteen cases showed normal rhythm for several hours, after which nodal and ventricular premature beats were observed preceding nodal or ventricular tachycardia, ventricular flutter, ventricular fibrillation and finally death.

Burnett and Taylor report on 1276 electrocardiograms of 85 healthy boys and 82 healthy girls, the data being obtained from series of periodic electrocardiograms begun at three or four weeks of age, these are to be continued to maturity. Right-axis deviation was found frequently in the first few months of life, decreasing in frequency between four and six months of age, P-R intervals and duration of the QRS complexes tended to be shorter in children than in adults.

Heard, Burkley, and Schaefer took standard and chest leads on 11 prematurely born infants. Tracings were made as soon as three and a half hours after delivery. For the most part the electrocardiograms were similar to those of adults.

Kossmann and his associates made a study of

have been noted. Normal or previously diseased hearts are affected by the lack of vitamin B, a condition which may be commoner than is supposed, especially among alcoholic patients. Therapeutic measures directed at providing vitamin B may give rapid or gradual improvement in the clinical symptoms.

Feil studied 38 cases of pellagra, all except 1 being associated with chronic alcoholism, of this group, 19 cases had changes in the electrocardiogram. Fourteen had no associated disease that might have influenced the tracing. The abnormalities noted were inversion of the T waves in either or both Leads 1 and 2, elevations of the S-T segment and high T waves. Lead 4 was abnormal in 12 cases, 4 of these having normal conventional leads. An electrocardiographic study of alcoholic patients without pellagra failed to show similar changes, and roentgenographic studies of the heart were normal. It is suggested that pellagra causes a physiologic cardiac disturbance inasmuch as pathological studies of 12 cases failed to show gross or microscopic cardiac abnormality.

Landt and Benjamin studied the hemodynamics and electrocardiograms throughout the course of the pregnancies of 19 women. It was found that pregnancy placed a definite burden on the cardiovascular system, but one normally within the bounds of physiologic compensation. Electrocardiographic changes, namely the presence of left-axis deviation, are due to a shifting of the position of the heart to a horizontal position.

Sprague emphasizes the necessity of distinguishing acute pericarditis with effusion from chronic constrictive pericarditis or Pick's disease. Tapping the pericardium gives prompt relief in the former condition, whereas surgery to remove the constricting pericardium is necessary in the latter. The rheumatic infection is a very uncommon cause of Pick's disease. The clinical syndrome of chronic constrictive pericarditis is similar to that of right ventricular failure, characterized by venous distention, liver engorgement, ascites and edema. Although dyspnea is common, orthopnea is rare. The size of the heart is usually normal and Broadbent's sign is rare. Electrocardiographic evidence is helpful in making the diagnosis.

Cushing reports 11 operated cases of chronic adhesive mediastinopericarditis. The electrocardiogram showed low voltage of the T waves and QRS complexes. In 4 of 7 cases the voltage increased after pericardectomy.

Menninger and Menninger present a group of interesting cases and a discussion of the psychic element in apparent cardiac disorders.

Yaskin discusses cardiac psychoses as disorders arising in the course of organic heart disease, and

cardiac neuroses as consisting of cardiac complaints without organic heart disease. In cardiac neuroses the complaints are related to the precordium or cardiac arrhythmias, and are only a part, even though the most prominent part, of a general neurosis due usually to an underlying anxiety.

Kirch reports his findings in the hearts of 9 athletes between fifteen and twenty-five years of age who were examined after sudden death. In 3 cases cardiac hypertrophy was present, no cause for it could be found other than athletic activities.

Gelman and Pusik report the cases of 2 men of Moscow, aged 112 and 122 years, who worked as farmers until the ages of 103 and 113, respectively. The former had hypertension, cardiac hypertrophy, a positive Kahn test and a normal electrocardiogram. The latter showed at postmortem a hypertrophied left ventricle and slight coronary sclerosis.

In cases of acute infection, Warfield believes that it is not the heart that fails, but that there is a peripheral collapse comparable to shock, so that the heart has no blood to pump. Just before death the heart dilates because of anoxemia. Digitalis is not helpful in peripheral collapse, and measures such as the giving of intravenous saline or dextrose to restore blood volume should be employed. Oxygen is indicated to combat anoxemia whenever cyanosis appears.

SYMPTOMS AND SIGNS

After studying the phonocardiograms of 120 normal infants two years of age and under, Segura reports finding three sounds per cardiac cycle in 38 per cent of the cases. He assumes that the third sound is due to auricular contraction because of its relation to the first sound, which it immediately precedes, and to the P wave of the electrocardiogram. No cases showed reduplication of either the first or second heart sound, or a physiologic third sound.

Although most cases with extrasystoles show no heart disease, Boas and Levy direct attention to premature beats that are of clinical significance. Such beats occurring during an infectious disease indicate myocardial damage due to toxicity. Auricular extrasystoles in the presence of heart disease may be the forerunners of auricular fibrillation. Extrasystoles in the presence of arteriosclerotic or coronary heart disease may indicate a progressive vascular lesion. They are frequently seen in association with attacks of angina pectoris. Extrasystoles originating from more than one focus are evidences of serious myocardial disease.

Schwartz observed attacks of transient ventricular fibrillation in 7 patients. He believes that the course of events following the fibrillation is as follows: a postfibrillatory pause, followed by a stand-

ducing the oxygen content of inspired air to 8 per cent in 13 normal individuals. He noted an increase in the cardiac rate, shortening of the P-R and QRS frequencies, increase of the P waves and flattening of the T waves. These changes disappeared on relieving the anoxemia. Oxygen given to 6 cyanotic patients gave electrocardiographic changes just opposite to those seen in the anoxic individuals.

Paschke found T-wave changes in the electrocardiograms of anemic rabbits following the administration of adrenalin. In normal rabbits adrenalin caused no change. He believed that the increased oxygen metabolism of the heart caused by the adrenalin in conjunction with the anemia resulted in a relative anoxemia of the heart muscle.

Kurtz and his associates studied 109 patients, taking electrocardiograms before operation, at intervals during operation and ten hours afterward. Various anesthetic agents exclusive of spinal anesthesia were employed. Only 21 per cent of the cases failed to show some type of disturbance. Arrhythmias were commonest, consisting of extrasystoles, displacement of the pacemaker, irregular ventricular action, complete heart block and paroxysmal auricular fibrillation. They also noted changes in the P-R interval and the S-T segment, and variations in amplitude of the QRS complexes and T waves, all of a transient nature.

PHARMACOLOGY

Nathanson, recognizing that structural changes in the heart are rarely sufficient to explain fatal cardiac syncope, has made a study of cardiac standstill and ventricular fibrillation, either of which may cause sudden death. The former was induced by reflex vagus stimulation and the latter by adrenalin. Drug therapy is useful in preventing these conditions, adrenalin serving to prevent cardiac standstill, and quinidine or acetyl-beta-methylcholine being useful to prevent ventricular fibrillation.

McGuire and Richards report the death of a normal thirty-one-year-old woman twelve hours after ingesting 300 gr of digitalis. Death occurred from respiratory failure. Electrocardiograms showed complete heart block, with an auricular rate of 170 and an idioventricular rate of 60 to 70.

Fifteen cases, 2 without and 13 with organic heart disease, are described by Tung. They illustrate the toxic effect of digitalis in causing auricular fibrillation. After the drug had been discontinued or reduced, a normal sinus rhythm was restored in from two to fifteen days.

Middleton and Chen present further evidence of the digitalis-like action of thevacin when given by mouth, based on a study of 40 cases of decompensa-

tion. The drug is thought to be useful in refractory cases or those intolerant to digitalis.

Strauss found that inorganic potassium iodide combined with silicic acid inhibited experimental adrenalin sclerosis in 60 per cent of the cases and cholesterol atherosclerosis in 70 per cent. Inorganic iodine alone had no effect.

Berliner offers experimental evidence of the possible effect of calcium on the normal human heart. An intravenous injection of 10 cc of a 20 per cent calcium gluconate solution gave electrocardiographic changes in 26 normal individuals. Bradycardia was present in 67 per cent, the P waves were flattened or inverted in 54 per cent, and the T waves were flattened or inverted in 92 per cent.

Sikl reports 2 cases examined post mortem following treatment with neosalvarsan. One patient was suspected of having syphilis, and the other was in the primary stage of that disease. A diffuse myocarditis, with an unusual eosinophilic infiltration, was found in both cases. Sikl believes that the condition was due not to syphilis but to an allergic reaction to the drug.

TREATMENT

Clark, Means and Sprague review the results of total ablation of the thyroid gland in 21 cardiac cases. Of these, 2 had angina pectoris, the remaining cases suffering from congestive heart failure. Fifteen patients are dead. It was felt by the authors that the operation had been worth while, judging from the results in 25 per cent of the cases. This series of treated cases is an early one, the operations being performed shortly after the procedure was introduced, and the cases selected were undoubtedly too seriously ill to expect good results. The writers believe that in selected cases of cardiac failure unamenable to medical measures, total thyroidectomy may give at least temporary benefit in about 50 per cent.

As a result of their experiments on dogs, in which they ligated the descending coronary arteries, Wiggers and Green came to the important conclusion that the drugs commonly used as vasodilators after coronary occlusion are in reality of little value in increasing the collateral flow to the ischemic myocardium. Theobromine and theophylline had an insignificant effect in their experiments and the nitrite group caused only a slight decrease in resistance to coronary flow in the ischemic area. The benefits of the latter effect were minimized by the lessened pressure in the larger collateral vessels. Adrenalin increased the resistance to the inflow of blood to the ischemic parts.

In experimental animals, Smith and his associates point out, preparations of theophylline have a marked dilating effect on the coronary arteries.

the Q waves in electrocardiograms of 178 normal adults. The records were made in the sitting and recumbent positions and in full inspiration and expiration. Q waves were found in Lead 1 in 40 per cent of the cases, in Lead 2 or 3 in 60 per cent, and in Leads 2 and 3 in 40 per cent.

Weiss and McGuire report 2 interesting cases of auricular tachycardia, the first of forty-three years' duration and the other probably of ten years' duration. Neither patient showed evidence of cardiac failure as a result of the tachycardia.

Orgain, Wolf and White found that paroxysms of auricular flutter and of auricular fibrillation occur not infrequently in persons without other evidence of cardiac disease. In a follow-up study of 54 cases (47 with auricular fibrillation, 5 with auricular flutter and 2 with both), they found but little important cardiac disease and a low mortality rate. They conclude that the prognosis for life in such cases and for the maintenance of an adequate circulation is good, and that a decrease or cessation of paroxysms is quite possible. It is thought that these transient arrhythmias are functional and not indicative of organic heart disease.

Seventy-two cases of complete A-V dissociation have been reported by Graybiel and White. Two thirds of the patients were men, and nearly two thirds of the cases were due to coronary disease. The disease of the heart responsible for the block was more important in determining the clinical course than was the block itself. The prognosis of the cases due to coronary disease was usually poor. Dizziness, syncope or convulsions were present in 44 patients, the only drugs of value in their treatment were ephedrine and adrenalin.

Tung has presented 2 cases of functional bundle-branch block with short P-R intervals. Both patients were subject to attacks of supraventricular paroxysmal tachycardia, on the cessation of which the electrocardiograms showed right bundle-branch block, apparently the usual rhythm for these apparently normal individuals. Although atropine did not prolong the P-R interval, as sometimes happens, it did abolish the vagal tone and result in a normal electrocardiogram.

Kurtz reports 6 cases of transient bundle-branch block. All the patients were over fifty-four years of age, with coronary disease or hypertension present.

Battro and his associates studied a group of patients with bundle-branch block to determine whether the ventricles contracted synchronously. Of 19 patients with left bundle-branch block, in 17 the right ventricle contracted first and contraction in the left ventricle was delayed. In the remaining 2 cases the ventricles apparently con-

tracted simultaneously. In 3 cases of right bundle branch block, in only 1 did the left ventricle contract before the right, there being no asynchronism in the other 2 cases. It was concluded that the electrocardiogram was not completely satisfactory in establishing the diagnosis of bundle branch block. The investigators' method of study was to record optically the apex beat, venous pulse, central arterial pulse and heart sounds.

Rosenblum and Sampson report that in a study of the electrocardiograms of 50 normal children an upward T wave in Lead 4 was a normal finding. The T_4 was upright in 64 per cent of the cases, diphasic in 32 per cent and inverted in only 4 per cent. There was no relation to axis deviation. The ages of the children varied from one month to sixteen years.

Robinow and his co-workers found that the T wave in Lead 4 might be upright, diphasic or polyphasic in normal children. Children with active rheumatic heart disease show a higher percentage of upright T waves than do normal children, with the T wave tending to be inverted with recovery.

Edeiken, Wolferth and Wood believe that an upright T wave in Lead 4 in the case of an adult who has not received digitalis should make one very suspicious of heart disease, especially of disease of the coronary arteries, even when the conventional three leads show no abnormality.

Faulkner reported 51 cases of fresh cardiac infarction. Lead 4 showed the only electrocardiographic evidence of infarction at some time or other in 8 cases, and in 3 the conventional leads never suggested its presence. Of 13 cases of acute infarction checked by autopsy, the electrocardiographic evidence was positive in 11. Of 20 cases that did not have infarction the electrocardiogram was negative in 16 and questionable in 4.

Levine and Levine report an electrocardiographic study of Lead 4 based on 44 postmortem examinations. In 12 cases with an absent Q wave in Lead 4, myocardial infarction was found at autopsy, and about half of a group of 15 patients with small Q waves showed myocardial infarction. Upright T waves in Lead 4 were observed in the absence of significant heart disease. Evidence was presented to show that myocardial infarction is not uncommon in angina pectoris. Of 100 patients with this diagnosis, 16 failed to show a Q wave in Lead 4, and 11 of these had normal standard leads. Two cases, 1 with bundle-branch block and 1 with tuberculous pericarditis, showed no Q waves in Lead 4.

Tigges studied the effect on the electrocardiogram of placing 15 normal individuals in a chamber with an atmospheric pressure equivalent to that at 5000 or 7000 meters above sea level, and by re-

They believe firmly that theophylline should be given in all cases of coronary disease.

Campbell and Gordon present a complete report of the treatment of 135 cases of auricular fibrillation with quinidine. This drug was successful in restoring normal rhythm in 64 per cent of the cases, and in 34 per cent it has been maintained for an average of four years. In 30 per cent of the cases auricular fibrillation recurred after an average period of two years. Twenty-five per cent of the cases treated between 1923 and 1928 still have normal rhythm after nine years, and 39 per cent of the cases treated between 1929 and 1934 have normal rhythm after two years. The authors believe that complete digitalization is important before starting quinidine. They stress the importance of the absence of congestive failure, of a greatly enlarged heart and of a long history of fibrillation. The presence of these factors in conjunction with valvular disease diminishes the likelihood of restoring or maintaining a normal rhythm.

Hoynes believes that diphtheria myocarditis can be prevented by the early use of 10 per cent glucose, injected intravenously.

With the growing popularity of the surgical treatment of hypertension by means of nerve resection, Allen, Lundy and Adson have devised a test which enables the examiner to predict the immediate effect that such a procedure will have on the blood pressure. They inject intravenously a solution of Pentothal Sodium to obtain a maximal temperature of the skin of the toes. The blood pressure following injection is proportionate to that which might be expected in the usual neurosurgical operation for hypertension.

of a primary source of cancer other than in the right upper quadrant. As my last consideration,—and the one I feel explains the enlargement,—I again come back to infection. I do not believe it was liver abscess. She had had fairly long-standing jaundice and a backing-up of bile, so that an infection in the biliary tree might well explain the enlargement of the liver.

So far as the laboratory work is concerned the bile in the urine is what one would expect with jaundice. The rapid respirations of 44, in the absence of thoracic disease, are explained by the tenderness of the mass in the upper abdomen, with resulting involuntary splinting and limited excursion of the diaphragm. The temperature of 100° F and the pulse of 100 are difficult to evaluate as they apparently are single readings. We have no way of knowing if this woman was running a septic temperature with points along her chart in excess of 100° F. The one reading is certainly suggestive of an infectious factor in her disease. The white-cell count is very high, especially when we consider the fact that the temperature was only 100° F—she may have been dehydrated which would help to elevate it. The high white-cell count suggests either a gangrenous area with a disturbance of blood supply or a very extensive infection. If the jaundice were intrahepatic in origin, I do not know how to explain the mass which was felt below the liver and which I have stated I believe to be an enlarged gall bladder. This brings us back to obstruction of the common bile duct as a primary cause of the jaundice—to me, the obvious answer. With obstruction of the duct she might have had extrinsic pressure as a cause, but against this is the fact that the story is connected with definite episodes of pain, furthermore, the jaundice was not a steadily progressive one. If it were a primary lesion of the head of the pancreas I think the start of her story would have been different.

If the obstruction of the duct was not extrinsic it must have been intrinsic, and considering not only this one point but the whole story, the most likely explanation is that the woman had gallstones, with common-duct involvement. However, I believe there are definite arguments against gallstones as the primary explanation of the picture, and it is not my first choice as the cause of her obstruction. In the first place, she was too old for a typical gall-bladder story of, at the most, only a few years' duration. Secondly, as I read over the history I get the impression that the pain was not severe, although it radiated in the typical distribution of gall-bladder colic. If she had had inflammatory obstruction as a primary cause, I believe that she would have had more striking pain. The third point against gallstones' being the source

of the trouble is the fact that her difficulties started with anorexia and weakness as outstanding features. The pain is stressed less than anorexia and weakness, and as the story progresses it is the weakness that is emphasized. There may well be stones for they are commonly associated with cancer in the bile ducts, but they are not the primary cause of her trouble. The last argument against gallstones being responsible for the picture comes in a consideration of Courvoisier's law, according to which a gall bladder with cancer should be distended,—as I believe this one is,—whereas with stones it should not be palpable.

The other intrinsic cause of jaundice is cancer of the bile ducts, and I believe that that is the lesion here. I think that she had cancer of the common bile duct, probably around the ampulla, with an associated cholangitis and, because of the pain in the left upper quadrant, a certain degree of pancreatitis. As I have said, she probably will show gallstones as an incidental finding.

CLINICAL DIAGNOSIS

Acute cholecystitis

DR. FAXON'S DIAGNOSES

Carcinoma of the common bile duct with associated cholangitis and a certain degree of pancreatitis

Gallstones (incidental)

ANATOMICAL DIAGNOSIS

Primary carcinoma of the gall bladder

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. There was no autopsy in this case so that I cannot answer all the questions that might be raised. However, a very careful exploration was done by Dr. Bartlett. The mass which was felt was an enormously enlarged gall bladder with a very thick, hard wall, it appeared obviously neoplastic. Nothing was felt in the bile ducts, and the head of the pancreas seemed negative. There was a little extension of the neoplasm from the gall-bladder area into the neighboring liver. There was no cirrhosis. A biopsy was taken of the gall-bladder wall which demonstrated adenocarcinoma on histologic examination. I think there is very little question that this was a primary carcinoma of the gall bladder.

A PHYSICIAN. Do you know what was inside the gall bladder?

DR. MALLORY. Unfortunately we do not. We have only the x-ray report from outside which showed "sand." I see no reason to doubt that it must have contained stones since carcinoma of the

CASE 24181

PRESENTATION OF CASE

A seventy-five-year-old Italian housewife entered the hospital with the complaints of right upper-quadrant pain, anorexia and weakness of three and a half months' duration.

She had been subject to indigestion for a number of years but had no definite symptoms until about three and a half months before entry when she first began to have attacks of moderate right upper-quadrant pain which occasionally radiated through to her back and rarely could be felt in the right shoulder when she moved her arm. She had occasional attacks of nausea and vomiting and noticed gradually increasing anorexia and weakness. These symptoms progressed until one month before entry when she became so weak and anorexic that she remained in bed all the time. At the onset of the illness, x-rays of her stomach and gall bladder were taken which were said to show cholecystitis and "sand" in the gall bladder. During the month before entry she had several attacks of mild jaundice, and occasional light-colored stools and dark urine, she also complained of itching. During this time she had no appetite and lost about 30 lb in weight. During the two days before entry the pain radiated to the left upper quadrant and became somewhat more severe, although it was still not excessive. Her bowels were always regular, without catharsis. About a month before entry she had passed a black stool. She had had no hematemesis or melena and no cardiorespiratory or genitourinary symptoms, except for moderate dyspnea on exertion. Her menopause had occurred twenty years before entry, and there had been no subsequent bleeding or discharge.

Physical examination revealed a well-developed, somewhat obese, obviously ill, elderly woman, apparently suffering from severe abdominal pain. The skin was coarse, dry, atrophic and moderately jaundiced. The heart and lungs were negative, and the blood pressure was 142 systolic, 68 diastolic. In the right upper quadrant extending 5 to 7 cm below the costal margin there was a hard, rounded, smooth, tender mass which moved with respiration. The liver edge could be felt in the epigastrium 4 cm below the xiphoid. There was no ten-

derness elsewhere in the abdomen, no otl could be made out, and peristalsis wa The skin overlying the tumor mass v what edematous. Pelvic and rectal exa were negative.

The temperature was 100°F, the pulse respirations were 44.

The urine contained 2+ bile but was normal. The blood showed a white-cell 54,000.

A laparotomy was performed on th entry.

DIFFERENTIAL DIAGNOSIS

DR. HENRY H. FAXON. In summary w elderly obese woman with disease confin right upper quadrant. If she has les where I believe they are more or less i to the disease we are considering.

There are certain points and findings shall take up separately which seem to most important in the story. In the fu she had a large, hard, tender mass below edge which moved with respiration and i ciated with edema of the overlying skin consider what that might be. Taking likely things first, she might have some walled-off abscess, but there is no etio such, and since it moves readily with res it cannot be retroperitoneal. Furthermore patient as obese as she apparently was, very much if a retroperitoneal mass cou been felt with the distinctness stated in the. If it were a tumor mass in the gastroi tract, possibly the transverse colon, she shoi had certain gastrointestinal symptoms and x-ray studies. So we come to the gall b. a distended gall bladder with probable i because of the edematous overlying skin a derness—as the answer to this palpable mass which was felt below the liver.

The second fact that is noted and seem nent is the enlargement of the liver, whi easily felt 4 cm below the xiphoid. Th feeling of the liver edge at that level does necessity mean it is enlarged, because it have been pushed down from above, but, been, some abnormalities would have been in the region of the diaphragm. If pushed by a subphrenic abscess we should have to some etiology for that abscess. An enlarge in an elderly person might be of cardiac but if this were the case, there should have other signs of passive congestion. If it wei to metastases we should expect an irregular than a smooth mass. Furthermore, if met: it would be secondary to a source elsewhere so far as the history goes we have no good evi

DIFFERENTIAL DIAGNOSIS

DR. GEORGE A. MARKS One of the striking things about the patient is the fact that when she entered the hospital, after six months of more or less continuous pain and vomiting, she is described as a well-developed and nourished person in apparent good health, the history states that there had been no recent weight loss. Her history during the previous six months was that of upper abdominal pain with frequent vomiting. To go back to her previous attack, we know that the pain was described as midabdominal, whereas the pain described on entry was epigastric, radiating to the shoulder blades. We know that she had polyposis of the intestinal tract. I think the lower intestinal tract can be ruled out, so far as her symptomatology is concerned. The bleeding that she showed once by rectum can be explained on the basis of the polyps found in the rectum, which leaves us with a differential diagnosis centered in the upper abdomen, a decision has to be made as to where the primary disease was and how many of her symptoms can be attributed to one portion of her gastrointestinal tract. The pain is described as radiating from the epigastrium, first to one side and then to the other, and the conditions which could produce pain of that sort are gall-bladder disease, ulcer, occasionally, if it is penetrating, and, less probably, disease of the pancreas.

I have more or less ruled out disease of the pancreas because it seems to me that a patient in apparent good health probably could not have had a six-month story of pancreatic disease. The gall bladder tract must be considered, not only in view of the report of a positive Graham test demonstrating a gallstone, but because of the nature of the pain. The degree of vomiting is not particularly well explained on this basis, and it seems to me that it points toward obstruction at either the outlet of the stomach or the duodenum. Her vomiting apparently was quite constant with the attacks of pain. Therefore we must consider this condition which we know she has—polyposis of the intestinal tract—and try to decide whether all her symptoms can be explained on that basis. We probably can consider the history reliable. She did have a polyp or some sort of intestinal tumor which caused an intussusception. Polyps are certainly the commonest tumors producing intussusception. The family history also fits in with that diagnosis, since there was a hereditary tendency.

Where would a lesion of this sort have to be located to produce this pain? Since the stomach is negative by x-ray, the duodenum is the next place to look. She has a tumor which has been demonstrated in the duodenum. It might be a

pedunculated gastric polyp that had prolapsed through the pyloric ring, but it is more apt to arise from the duodenum itself and be of sufficient size to produce an intermittent obstruction. A tumor 3 cm in diameter would be large enough. It is evident that the tumor is not located in the second portion of the duodenum because there is no history of jaundice, unless we interpret the three-day attack of itching as a subclinical manifestation.

The question of gall-bladder disease has to be considered. She may well have had a coincidental cholecystitis and cholelithiasis. We might ask whether she had passed the stone, since the previous Graham test showed it, and the one done here did not. It is possible that the stone was passing or had just passed and had lodged in a diverticulum in the duodenum. These possibilities are a little far-fetched.

Then there is the question of whether this lesion in the duodenum was cancer. These polyps are prone to become malignant. Because of her general condition I feel that it was either not carcinomatous or still of a very low grade of malignancy. The fact that cancer of the duodenum usually runs a very rapid course of six, eight or nine months also makes it seem unlikely. If this had been cancer for the period of her present illness she would not have been in as good condition as she seemed to be on entry. So I leave my diagnosis as multiple polyposis of the intestinal tract, principally in the upper intestinal tract, I believe that the symptoms were caused by a large pedunculated lesion in the duodenum, which caused intermittent duodenal obstruction and probably was not malignant. Whether she has gall-bladder disease is a question.

DR. GEORGE W. HOLMES Here in a loop of the small bowel is a shadow which is obviously a polyp. From this area is a dense line which is at a right angle to the usual markings, suggesting intussusception. Here is another shadow in the duodenum which might be due to a polyp. There are several other suspicious areas. Here is a portion of the sigmoid, and it shows the rather characteristic appearance of polyp. The part of the examination which interests me most is the appearance of the duodenum. Here is a localized film of that area. It looks to me more like an ulcerative area than a straight polyp. I doubt very much if a polyp in the duodenum could produce that degree of deformity of the mucosal pattern. It could be polyp plus ulceration, or it could be ulcer alone.

PREOPERATIVE DIAGNOSIS

Polyposis of intestines

gall bladder almost never develops except in the presence of a stone

DR FAXON Was there any gangrene?

DR MALLORY There was no obvious gross necrosis, but white counts of this level are not uncommon in carcinoma victims

CASE 24182

PRESENTATION OF CASE

A thirty-three-year-old Sicilian housewife entered the hospital with the complaint of bilateral upper abdominal pain radiating to both shoulders

Two and a half years before entry, after a series of attacks of midabdominal and back pain, she developed acute intestinal obstruction with continuous vomiting for five hours. She was taken to another hospital where a laparotomy was done. Intussusception caused by a tumor of the intestine was found and relieved. Two months after the operation she had a miscarriage. After that she was free from abdominal pain until six months before entry when she began to have a heavy feeling in the pit of her stomach after eating, especially when she ate fried or fatty foods. This was frequently accompanied by nausea and vomiting of the food eaten. Occasionally she vomited small amounts of foamy material between meals. About three months before entry she began to have attacks of sharp persisting pain after eating which started below the ribs on the left, radiated to the left shoulder blade, then to the region below the right ribs and finally to the right shoulder. Her vomiting continued, occurring almost daily. About two months before entry she had an attack of shaking chills which lasted about an hour. Following this episode she had severe generalized itching without jaundice for a period of three days. Her stools were not clay colored, nor was her urine dark. One and a half months before entry she was studied in the other hospital where a Graham test showed a stone in her gall bladder. About one month before entry the attacks of radiating epigastric pain began to come on at night, without relation to meals. They were usually accompanied by vomiting. Two weeks before entry, after taking an enema, she passed a small amount of blood by rectum. She had no further melena and never any hematemesis, jaundice or diarrhea. Her appetite remained good, but she had been unable to eat much because of vomiting. For the few months before entry she had increasing constipation so that it was necessary for her to take milk of magnesia, mineral oil, and finally enemas as often as two or three times a week. She passed

large amounts of gas by rectum. Often she had to defecate, but on attempting to do so passed little or no feces. She had had recent weight loss.

Five years before entry she had had her appendix removed at another hospital. Her past history was otherwise noncontributory.

Her father died at the age of thirty-three following an appendectomy and two other abdominal operations. He had some sort of "stomach trouble," the exact nature of which the patient did not know. The surgeon who treated him at the time of his death said that he had "hole in his stomach or intestine." One month before patient's entry to this hospital her nine-year-old son died at another hospital of polyposis of intestine complicated by intussusception. The diagnosis was confirmed at autopsy. One of her brothers had a questionable history of polyp. There was no family history of cancer.

Physical examination revealed a well-developed and nourished woman in apparent good health. The heart and lungs were negative, and the blood pressure was 120 systolic, 70 diastolic. There was no spasm or tenderness of the abdomen. Both the right and the left colon were palpable, but there were no other masses. Rectal examination revealed two or three polyps easily palpable at the finger. Proctoscopy revealed three more, measuring about 1 cm in diameter and located 11 cm from the anus.

The temperature was 98.6°F, the pulse 90, and the respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 4,210,000 with 75 per cent hemoglobin, and a white-cell count of 53. The guaiac test on the stool was 2+. The blood Hinton test was negative.

A Graham test of the gall bladder was negative. Two barium enemas showed a pedunculated polyp measuring about 2.5 cm in diameter with a long pedicle located in the proximal sigmoid. No other polyps were demonstrated. Two gastrointestinal x-ray series showed a normal esophagus and stomach. The pylorus opened very slowly, and the duodenal cap did not fill completely although there was gross evidence of a lesion could be demonstrated in it. There was a definite tumor mass measuring 3 cm in length in the second portion of the duodenum. Hourly follow-up films of the small intestine showed polypoid defects in several loops, particularly in the upper part of the intestine. At times, one of the polyps in the upper jejunum seemed to be intussuscepted.

A laparotomy was performed on the twenty-first day.

ANNUAL MEETING

THE Annual Meeting of the Massachusetts Medical Society will be held on May 31 and June 1 and 2 at the Hotel Bradford in Boston. Every effort has been made to make these three days unusual ones in interest, instruction and entertainment for members—and their wives—from all parts of the State.

An outstanding group of scientific exhibits has been arranged, each demonstration being under the supervision of experts in their particular field. Never before has there been so extensive a demand on the part of commercial exhibitors, and all the available space has been taken.

Following the successful example of 1937, the second day will be given over to a Combined Clinical Meeting of practical interest to all branches of the profession.

In addition to the strictly medical portion of

the program, the Boston Physicians' Art Society is to hold an exhibition of work done by its members. It may be remembered that a similar display some years ago was one of the more popular features of our spring session.

An attractive feature of the meeting is the program for the entertainment of the wives of members. This has been prepared by the Ladies' Committee, which has played such an important part in the success of our gatherings in recent years.

Finally, plans are being made for a golf tournament to be held at one of the nearby country clubs.

Check off the above dates on your calendar now and plan to come to the Annual Meeting!

NATIONAL HOSPITAL DAY

THE organization of special days and special weeks, of which there seems no end, has never aroused much enthusiasm in our humble minds. National Apple Week never moved us to consume more applesauce, and we doubt if it has meant bigger and better apples, or healthier children.

Mother's Day has not, in our opinion, added any dignity or honor to motherhood. Perhaps, the chief contribution from this special day has been a few added jingles to the telegraph company's fifty-seven or more varieties of canned messages. Every day is, or should be, a sacred day for motherhood, and it seems quite possible that the emphasis on one day tends to give the thoughtless and selfish person more license to forget the deep significance of motherhood for the other three hundred and sixty-four days of the year. Some people's religion finds expression only on Easter, and we do not have much respect for that sort of religion.

When National Hospital Day was established, we were frankly prejudiced. Here was just another day when hospitals were to be "played up" and then forgotten for the rest of the year. Hospitals, like mothers, deserved better.

However, as the years have gone by, and we have noted the great numbers of people who have interested themselves, and been interested in this

DR MARK'S DIAGNOSES

Multiple polyposis of the intestinal tract Pedunculated polyp of the duodenum with intermittent obstruction

ANATOMICAL DIAGNOSIS

Adenomatous polyps

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY This patient was operated on by Dr Edward L Young because of the severity of the symptoms and the evident obstruction. He found multiple polyps including one in the duodenum which had caused intussusception. He resected seven separate polyps which were all more or less close to that region. He did not at-

tempt to do anything about the polyp in the large bowel and wound up his operative note by saying that the patient probably could not be cured by surgery but that it had been necessary to remove at least the one polyp that was causing the intussusception. Following operation she convalesced satisfactorily for a few days and then had one episode of very severe bleeding by rectum, unquestionably from the polyp in the cecum. After that she did better.

Dr Young examined the entire bowel as thoroughly as he could. No ulcer was noted in the duodenum, and nothing was found in the gall bladder.

DR HOLMES Was it a grape-like cluster of polyps?

DR MALLORY Yes

NATIONAL HOSPITAL DAY

THE organization of special days and special weeks, of which there seems no end, has never aroused much enthusiasm in our humble minds. National Apple Week never moved us to consume more applesauce, and we doubt if it has meant bigger and better apples, or healthier children.

Mother's Day has not, in our opinion, added any dignity or honor to motherhood. Perhaps, the chief contribution from this special day has been a few added jungles to the telegraph company's fifty-seven or more varieties of canned messages. Every day is, or should be, a sacred day for motherhood, and it seems quite possible that the emphasis on one day tends to give the thoughtless and selfish person more license to forget the deep significance of motherhood for the other three hundred and sixty-four days of the year. Some people's religion finds expression only on Easter, and we do not have much respect for that sort of religion.

When National Hospital Day was established, we were frankly prejudiced. Here was just another day when hospitals were to be "played up" and then forgotten for the rest of the year. Hospitals, like mothers, deserved better.

However, as the years have gone by, and we have noted the great numbers of people who have interested themselves, and been interested in this

day, we must frankly admit that our attitude has changed, and the change has come just because those who have promoted this cause have emphasized on this one day the permanent, or day-by-day, influence of the hospital as a great community blessing.

In the first place, National Hospital Day has promoted an unusual co-operation among hospital workers throughout the nation and Canada. The leading hospital authorities of the country have contributed to the plans and programs, and this has resulted in an unmeasured benefit to thousands of boards of trustees and administrators of institutions in the smaller communities, and it has stimulated not only knowledge and belief in the hospital, but has added real efficiency to the country's hospitals as a whole. This alone would justify the day.

But the real reason for organizing National Hospital Day was to give information and enthusiasm to the public about the progress of medicine and medical care in our hospitals. The public generally has been woefully ignorant of the real facts regarding medical care. After all, people do not have the same feelings about hospitals as they do about mothers and apples. Most people do not think of hospitals at all, unless compelled to, and then they usually think of them in terms of fear, or pain, or sorrow. When patients leave a hospital where they have been served well, they generally think of that hospital only in personal terms. They do not think of the great contribution of the hospital to the community as a whole.

National Hospital Day was conceived, in great part, to educate the public as to how the hospital serves as a bulwark against those diseases which menace the community. Just as a great reservoir is understood by the public to be a protection against the menace of fire, so should the hospital be considered as a great protective influence against community diseases. The activities surrounding this day have brought about that understanding. You cannot, even if on only one day a year, interest hundreds of thousands of people in visiting hospitals, in hearing factual and favorable speeches and radio addresses about them,

in reading news items and editorials explaining their work, without creating a favorable understanding and reaction.

In like manner, the general public has not understood the reasons for the high cost of medical care. Recently a friend of ours went to a local hospital, and complained, at first, of the eight dollars per day, plus extra charges, which he was paying for his stay. He said to us on our first visit, "These people are certainly not in this for their health." A few days before he left, however, the superintendent, knowing of his feeling about the costs of his care, took occasion to make a trip around the hospital with him. They visited the radium plant, where two grams of radium are housed. It was explained to him that this amount of radium, no larger than a small pea, cost the hospital \$140,000, and that the emanation plant, through which the healing gas is pumped off in small capsules to be used by the doctor, cost an additional \$10,000. He was taken to see a large 400,000-volt x-ray therapy machine, which cost over \$25,000. He saw a special solution room, where an average of fifty solutions a day are prepared for the surgeon to use for patients before and after operation. He saw enough of the hospital equipment to be aware of the tremendous costs of these necessary things. He visited the kitchens, where 868,160 meals are served each year, 70 per cent of them being special diets. He saw diabetic trays, on which every mouthful of food has to be weighed and measured for each individual patient. He visited the laundry, where 2,143,377 pieces of laundry, a matter of 615 tons, are handled a year. He was made aware of the special precautions that have to be taken regarding much of the hospital laundry. He visited the laboratories, the operating suites, and so forth. It changed his whole attitude. Instead of complaining of the high costs, he wondered how the hospital could do it for so little.

All this is what National Hospital Day hopes to do for the public in general, and what it has done to a very great extent. And that is why we believe National Hospital Day is a great national benefit.

CASE HISTORY No 70 PREMATURE SEPARATION OF
THE PLACENTA

A twenty-four-year-old primipara, at term, but not in labor, was admitted to the hospital because of painless vaginal bleeding, amounting to 1 or 2 oz., which had occurred about fourteen hours previously.

Her family history was unimportant except that one sister had died of tuberculosis. There was no history of diabetes, cancer or hemorrhagic disease. Her past history had been negative, and her pregnancy normal.

Physical examination upon entry revealed a healthy, well-developed and nourished young woman, who was in no distress. Her heart and lungs were normal. The blood pressure was 120 systolic, 60 diastolic, and the pulse 80. The uterus was soft, and a normal fetal heart was heard. The pelvic measurements were those of a funnel type of pelvis. As the patient was not bleeding and not in labor, she was put to bed under observation. No rectal or vaginal examination was done. Two days after entry, under gas-oxygen anesthesia, the patient was examined vaginally to determine the source of bleeding. No placenta previa was felt, there was no cervical erosion or varicosities. Bright-red blood was found to be oozing from the internal os. The cervix was soft and patulous. The vertex was presenting with the head in the pelvis. The membranes were artificially ruptured to induce labor. Two and a half hours after this procedure, the patient went into labor, and four and a half hours later, when the cervix was fully dilated she was delivered by low forceps of a normal, 6 lb., 4 oz., female child in good condition. The forceps operation was performed because of fetal distress. There was no unusual bleeding during labor or after delivery.

The placenta revealed a very short (26 cm) cord, which was in all probability the cause of the fetal distress. There was no gross, old or recent hemorrhage on or in the maternal surface of the placenta. (However it is not always possible to demonstrate recent, intrapartum hemorrhage of the placenta, even in undoubted cases of premature

separation, such as placenta previa, when the bleeding is known to be due to separation of the placenta from its site of attachment.) Microscopically, the decidua showed cystic areas of degeneration with hemorrhage—a finding often associated with clinical and gross pathologic evidence of hemorrhage into and on basal decidua (premature separation of the placenta).

The patient ran an afebrile puerperal course, and she and her infant were discharged well on the fourteenth day.

Comment. Bleeding at term comes from some type of placenta previa, erosion of the cervix, varicose veins, a separation of a normally implanted placenta or more often from the separation of a low-attached placenta. There is no note in this case that preparations were made for bagging or for cesarean section when the examination showed the cause of bleeding. These precautions should be routine. The softness of the uterus and the presence of a normally functioning fetal heart ruled out an entirely separated placenta. The small amount of bleeding and the patient's pulse showed that the amount of intrauterine bleeding was slight. The examination vaginally ruled out any type of placenta previa, and also erosion of the cervix and vaginal or cervical varicosities, by a process of elimination the bleeding must have been coming from a placenta that had separated to a very small extent. The conservative method of rupturing the membranes to induce labor when the cervix is adaptable is the simplest method of treatment at hand. The facts that the patient started in labor so quickly and that the cervix dilated so rapidly are evidence that the patient was at term and that the cervix was well obliterated when the membranes were ruptured. While this patient's condition did not absolutely necessitate that the blood be typed and matched, it must be borne in mind that in most bleeding cases it is a piece of routine that should always be followed.

ERRATUM IN DIRECTORY

In the recently published *Directory* through a clerical error, the name of Dr. Morton H. Langill, of 36 Pleasant Street, Worcester, was omitted.

The name which should have been removed is that of Dr. William E. Langlois, of 25 Trowbridge Road, Worcester.

Wednesday, May 11, at 4 00 p m, at the Cambridge Municipal Hospital, Cambridge Street, Cambridge. Subject Acute Anterior Poliomyelitis—Its Diagnosis and Treatment. Instructor R Can non Eley Edmund H Robbins, *Chairman*

MENTAL HEALTH

Mental health has long been appreciated as a most desirable possession, and rightly so as mind is the controlling factor in all of our activities and endeavors Physical health, naturally, is also greatly to be desired It can exist without the former, and mental health can be present in a sick body, but in general, the state of each one has a direct effect on the other, for good or ill So, having the sound mind and the sound body together, leaves little else to be desired To try and separate mind from body or vice versa is a futile and undesirable procedure because it cannot be done So long as there is life, the two are inseparable, whatever affects one affects the other, to a greater or less extent It is a matter of common knowledge that physical illness has its effects on mental conditions, between the extremes of simple annoyance at being kept in bed by a common cold, to the wild delirium of some severe and toxic disease But our concern tonight is, rather, with the effects of the mind on the body and its functions The healthy mind helps the body to re-

spond in its most effective manner, without putting obstructions in the path of adequate response and behavior

In order to understand this, it is necessary to appreciate certain fundamental facts concerning the interrelation of mind and body Briefly, the latter is composed of the bony framework to which muscles are attached for the purpose of locomotion, and within which are various departments, each with its special organs and functions—such as the stomach and intestines for digestion, the lungs for breathing, and so on The apparatus that coordinates all the body functions into a workable, going concern is the nervous system This system, in brief, is made up of the brain and the nerves The former is the great central office into which messages are brought, and from which orders are issued to all parts of the body by means of the communicating wires, the nerves A part of this nervous system automatically controls the various physical functions without conscious intervention on our part, it has local centers, substations, below the level of our conscious awareness, thus making it possible for the higher centers to function on activities outside the body itself It is, however, definitely influenced by our conscious mental activities.

In order to react as a whole toward the constant changes within us and around us, we have mobilizing responses bringing the entire body into action toward specific ends—namely our emotions Fear mobilizes us to escape from danger, to make life safer, anger, to overcome obstructions, love, to find a mate and have children These primarily serve the demands of self Above these, we have intelligence which enables us to handle these mobilizing responses more effectively And, highest of all, we have the spiritual factor which demands that we live beyond self, that we put at least some of our energy—the more the better—to work for others, in spite of self interest It is in the conflict between this unself seeking factor and those that are self seeking that the greatest difficulties lie It is lack of understanding how to manage and resolve these conflicts that causes no end of unhappiness and mental and physical ill health It is characteristic of emotions that they want immediate release in action—I am scared, I want to run away now, not tomorrow It is a function of intelligence to delay that immediate reaction, if even for a fraction of a second, so as to help select the most effective manner of response, thus giving the spiritual factor its chance to influence the final action toward what is fairest and best, not for self alone but for others

Now when energy is released by emotional response, it must needs be put to some use, if that use is not directed outward, the energy turns in, so to speak, and the automatic body functions become overcharged and, therefore, are disturbed For instance, the irritable person, whether he be so from his own ill nature or from his unhappy situation, has habits of petulance, and the resultant excess of energy interferes with, say, his digestion and he is a chronic dyspeptic He generally attributes his irritability to bad digestion when, really, he is dyspeptic because he is irritable As children, most of us, in the face of some unpleasant demand, have advanced the excuse of being too tired or feeling sick, even to the point of becoming actively ill, thus trying to avoid the unpleasant task The great majority learn that this is not an effective way of meeting life, and grow away from it But, when things are not going our way, every one of us is capable of re turning to his childhood methods if he does not keep a good natured and honest eye on himself Just because we accumulate a few years and are, supposedly, 'old

enough to know better, does not guarantee that our emotions will always stay where they belong.

Because a person is mature in years, then, is not a reason in itself for having acquired complete and satisfactory emotional control. Ignorance and intolerance of this fact produce an obstructive attitude toward effective understanding, treatment and improvement in self-management. Overemotional, hypersensitive mental habits of response produce disorder of mental and physical function, a state commonly called 'neurotic.' This is illness just as much as a cold, pneumonia or a broken leg is illness, and ought to be handled in the same way by seeking competent help. It is only rarely wilful, and never imaginary. The disturbance in digestion, circulation or what not, produces distressing symptoms. One can imagine that these symptoms are caused by something disastrous, but the discomforts themselves are absolutely real. In such cases of nervous origin, examinations do not disclose any physical defect to explain the condition but the disorder will continue as long as the situation remains unsatisfying, or until the right attitudes are acquired. Obstructive prejudice against being thought neurotic—"just nervous"—prevents rational search for the cause hidden in the mental life, and the sufferer is an easy prey to quacks and charlatans, false sciences and pseudo-religious cults. Largely due to impressive suggestion and the promise of cure, the troubled mind is diverted and allows the body to carry on undisturbed by excess of emotion, producing apparent improvement. But only when the fundamental causes have been discovered, faced and readjusted can real and permanent improvement be effected. To acquire healthy minded attitudes,—and there has never been any greater need of this than today—training should begin in the cradle. Our first contacts with life are in our immediate families, making impressions upon us which may influence us throughout our lives. Therefore, it behooves every family circle to appreciate the importance of these first impressions, and later ones as well, and make the home a place where every possible influence is for stability. One of the best things about the family unit is that it presents a ready made, first hand opportunity for co-operative effort. However, when we attain adult, independent capacities, it is an error to believe that these impressions cannot be modified. If attitudes of mind making for healthy living have not been acquired at home, they can be acquired by one's own individual study and determination, by an honest evaluation of one's personal liabilities and assets.

It is gratifying to appreciate the fact that one does not have to be a superman to possess a healthy mind. The very humblest person can, and often does, reveal the desirable qualities of steadfast common sense, stability and courage that make for sound living. The great majority of persons, even in the face of very difficult conditions and limitations, can, with determined and intelligent effort, attain to effective and satisfactory mental health.

Q I am much interested in this important subject, and wonder if you can tell me one or two things more specifically. You speak of the mind affecting the body; could you not also say that, under certain circumstances, the mind has a bad effect on itself?

A Most decidedly—and an excellent point. For example, a too rigid or stubborn person, by persisting in thinking he is always right, may have perfect physical health, but his pugnacious inflexibility prevents normal friendly relations, and results, in the long run, in a querulous and unhappy mind. Or, again, many vigorous people make themselves unhappy by unnecessary fears, cross-

ing bridges before they come to them, being sorry for themselves, dramatizing minor limitations, brooding over hurt feelings—all of which are, primarily, indications of unhealthy attitudes interfering with the normal, useful activity of the mind. Yes, a great deal of maladjustment is due to the mind working against itself.

Q Why do so many people, and even some doctors, feel that nerves mean weakness of character, and even something to be ashamed of?

A Primarily, I believe, because of prejudice and not knowing the first thing about it—perhaps also annoyance at the particular difficulties attendant upon these disorders, and a mistaken belief that they are wilful. Also, this attitude can be an unconscious attempt to protect one's self against the discovery of one's own neurotic liabilities. It is well to remember that practically everyone who has normal intelligence, feelings and sensitiveness can, under a sufficiently aggravating combination of circumstances, get into nervous difficulties. So it is just as well to be understandingly tolerant.

Q You spoke of the necessity for self-examination and evaluating one's abilities, and so forth. Do not these tend to morbid interest in self, and even selfishness?

A No, not if it is approached in the right way. Of course, if it is an emotional, self-pitying process, it can lead to self-indulgent attitudes. But, if it is undertaken with a genuine desire for broader knowledge and for better methods of using one's capacities most effectively, it should, and does, enable one to get more away from self.

Q Am I right in thinking that mental health comes into the field of medical practice?

A Most decidedly yes. As medicine is concerned with all forms of human suffering, it is vitally concerned with the study, treatment and prevention of mental illness and, therefore, everything that makes for mental health.

Q If one wants help in sickness of this sort, how can one go about finding it?

A The family doctor can tell if the situation requires special care, and should be able to put you in touch with a competent specialist—just as he does in other conditions when they get beyond his field. All the best large hospitals have clinics devoted to this practice. Valuable information regarding lecture courses, books and pamphlets, and on occasion even personal advice, can be obtained from the Massachusetts Society for Mental Hygiene, at 3 Joy Street, Boston; this organization is very active in promoting a better understanding of things to do with mental health.

Q Can you suggest any rules that help to keep the mind healthy?

A Let us say suggestions, rather than rules. First, a good balance should be arrived at between work, rest and recreation, without over or underemphasis on any one of them; a hobby as well as a job helps here. Cultivate attitudes of tolerance, good nature, friendliness, and a wholesome, objective, militant optimism; reasonable care of and attention to the body—not abusing it with exaggerated care or with senseless high pressure and overstimulation of any sort. Keep the mind active in objective thinking but give it some opportunity for relaxing, constructive meditation. Encourage healthy religious beliefs, a confidence in something higher than and beyond self. And, finally, if the sentiment of pity is aroused, see to it that it is pity for others and not for one's self.

DEATHS

HOFFMAN—DONALD C. HOFFMAN, M.D., of New York City, died April 20. He was in his forty first year.

Born in Indiana, he was graduated from Depauw University and received his degree from the Harvard Medical School in 1926. Dr. Hoffman was at one time director of the clinical laboratory at the Boston City Hospital and for the last four years was a medical director for the Metropolitan Life Insurance Company in New York City. He spent some time in cancer research at the Rockefeller Institute.

Dr. Hoffman was a former fellow of the Massachusetts Medical Society.

His widow survives him.

MINOT—JAMES J. MINOT, M.D., died April 30, at his home, 188 Marlborough Street, Boston. He was in his eighty sixth year.

Born in Forest Hills, he attended Mr. Dixwell's School and Harvard University and received his degree from the Harvard Medical School in 1878. Upon his graduation he studied at Vienna, Berlin, Paris, Leipsig, London and other European cities. Dr. Minot was a physician at the Boston Dispensary, Carney Hospital and the Massachusetts General Hospital.

Best known for his work in the prevention and care of tuberculosis, he was one of the founders of the Boston Tuberculosis Association. He was president of the Massachusetts Emergency and Hygiene Society, fellow of the Massachusetts Medical Society, member, Boston Society for Medical Improvement, fellow, American Medical Association, member, American Association for the Advancement of Science, and a member of the overseers committee of the Harvard School of Public Health.

His wife died many years ago. He is survived by three sons and ten grandchildren.

MISCELLANY

NINTH ANNUAL CITY HEALTH CONTEST

The Chamber of Commerce of the United States recently announced the following awards for the 1937 City Health Conservation Contest.

Boston, Massachusetts, wins the first award in Group I (cities of over 500,000 population). Additional awards in this population group go to Cleveland, Ohio, and Pittsburgh, Pennsylvania.

In Group II (cities of from 250,000 to 500,000 population) Louisville, Kentucky, and Providence, Rhode Island, receive first awards, and an additional award goes to Dallas, Texas.

In Group III (cities of from 100,000 to 250,000) the winner is Hartford, Connecticut. Awards also go to Grand Rapids, Michigan, Yonkers, New York, Reading, Pennsylvania, Erie, Pennsylvania, Honolulu, Hawaii, Lynn, Massachusetts, Tacoma, Washington, and Knoxville, Tennessee.

In Group IV (cities of from 50,000 to 100,000 population) Sacramento, California, gets the first award and other awards go to Evanston, Illinois, Newton, Massachusetts, Greensboro, North Carolina, and Saginaw, Michigan.

In Group V (cities of from 20,000 to 50,000 population) Greenwich, Connecticut, is the winner, and Plainfield, New Jersey, Auburn, New York, Winona, Minnesota, Elmira, New York, Watertown, New York, Pittsfield,

Massachusetts, Maplewood, New Jersey, and Orange, New Jersey, are given awards of merit.

In Group VI (cities of less than 20,000 population) Englewood, New Jersey, is the winner, and awards go to Hibbing, Minnesota, Virginia, Minnesota, and Middletown, New York.

In addition to these prizes, special awards were given to Baltimore, Maryland, Brookline, Massachusetts, Detroit, Michigan, Hackensack, New Jersey, Newark, New Jersey, New Haven, Connecticut, Pasadena, California, Schenectady, New York, and Syracuse, New York. Each of these cities has twice or more won first awards in its respective population groups (and is therefore barred from the regular contest) and has during 1937 maintained its previous high standards of health protection services.

The City Health Contest is conducted annually by the Chamber of Commerce of the United States in co-operation with the American Public Health Association. Awards are given, in each of the six population groups, to those competing cities which, in the opinion of a committee of health experts, have during the past year dealt most effectively with their local health problems. These are *not* prizes for the healthiest cities, they are prizes for the most effective efforts to meet local health problems. Awards are not based on health department programs alone but rather on the community wide efforts of all agencies and groups including the work of private practitioners of medicine and dentistry.

RÉSUMÉ OF COMMUNICABLE DISEASES
IN MASSACHUSETTS FOR MARCH, 1938

DISEASES	MARCH 1938	MARCH 1937	FIVE YEAR AVERAGE
Anterior poliomyelitis	0	0	1
Chickenpox	1943	1471	1253
Diphtheria	17	12	42
Dog bite	788	762	608
German measles	92	105	1229
Gonorrhea	463	462	485
Lobar pneumonia	654	790	606
Measles	1258	3774	4212
Meningococcus meningitis	9	31	18
Mumps	1321	971	1144
Paratyphoid B	8	0	0
Scarlet fever	1712	1184	1335
Syphilis	635	657	489
Tuberculosis pulmonary	299	295	378
Tuberculosis other forms	41	9	42
Typhoid fever	3	0	1
Undulant fever	4	0	1
Whooping cough	572	2013	1259

*Based on figures for preceding five years

RARE DISEASES

Diphtheria was reported from Athol, 1, Boston, 1, Canton, 1, Lawrence, 1, Monson, 1, New Bedford, 1, Norwood, 1, Plymouth, 1, Salem, 3, Shirley, 1, Somerset, 1, Somerville, 1, Westboro, 2, Worcester, 1, total, 17.

Meningococcus meningitis was reported from Boston, 4, Holyoke, 1, Ludlow, 1, Melrose, 1, New Bedford, 1, Newton, 1, total, 9.

Paratyphoid B was reported from Boston, 1, Cambridge, 1, Reading, 6, total, 8.

Pfeiffer bacillus meningitis was reported from Brockton, 1.

Septic sore throat was reported from Athol, 1, Beverly, 2, Boston, 12, Everett, 1, Gardner, 3, Greenfield, 1, Lowell, 1, Lynn, 1, New Bedford, 1, Northfield, 1, Oxford, 1, Quincy, 1, Somerville, 1, Wrentham, 1, total, 28.

Trichinosis was reported from Boston, 4, Worcester, 1, total, 5.

Typhoid fever was reported from Boston, 1, Greenfield, 1, Randolph, 1, total, 3.

Undulant fever was reported from Fall River, 1, Gard-
ner, 1, Sunderland, 1, West Boylston, 1, total, 4

Chickenpox for the third consecutive month showed
record high figures.

The incidence of diphtheria was considerably below the
five year average.

Measles, German measles, whooping cough and pulmo-
nary tuberculosis were reported below the five year aver-
age.

Typhoid fever continued to show low incidence.
Lobar pneumonia, undulant fever and mumps were
reported above the five-year average.

Paratyphoid fever showed record high incidence.

The incidences of meningococcus meningitis and tuber-
culosis (other forms) were below the five year averages

Scarlet fever continued to be reported at a high figure.

The reported cases of animal rabies manifested a wider
distribution throughout the State. New foci were noted
in Canton and Montague. Previous foci in Uxbridge,
Westboro, Newton, Andover and Methuen were active.

CORRESPONDENCE

TUBERCULOUS SKIN LESIONS

To the Editor For many years I have read the "Cabot
Case Reports" with much profit. Two records that were
recently published in the *New England Journal of Medi-
cine* will be the subject of the remarks in this communi-
cation. These cases command interest, for they relate to
a field intermediary between internal medicine and der-
matology.

The first of these is Case 24111 (218 485-489, 1938).
This proved to be an instance of miliary tuberculosis ac-
companied by cutaneous lesions. The eruption was vari-
ously regarded as erythema nodosum or erythema indura-
tum. The occurrence of scars—even small, slightly de-
pressed ones—was in itself sufficient to eliminate the
former diagnosis. It is evident, from the discussion, that
erythema nodosum is still being considered as most com-
monly associated with rheumatic fever and tuberculosis.
In a critical survey of the data bearing on the relation
of this dermatosis to rheumatic fever, I (*Am. Int. Med.*
10 1686-1707, 1937) have presented evidence indicating
that erythema nodosum is probably not a manifestation of
rheumatic fever in the strict sense in which that disease
is understood today. In that paper the difficulties in ar-
riving at a diagnosis of erythema nodosum were also dis-
cussed, and among the simulating conditions mentioned
was a certain form of tuberculide. Case 24111 provides
an excellent illustration of that dermatosis, and the im-
portance of the presentation is increased by the nature of
the postmortem findings. I am taking this opportunity to
quote the description in my article for the purpose of
showing the essential similarities between my observa-
tions and those in Case 24111.

There is a more acute variety of erythema indura-
tum revealing transitions to papulonecrotic tubercu-
lides and resembling *erythema nodosum*. Of this
variant I have encountered three examples, character-
ized by the occurrence of cervical lymph node tuber-
culosis, typical papulonecrotic lesions about the el-
bows, and painful purplish red nodular efflores-
cences on the lower limbs. The latter simulated
ordinary erythema nodosum the resemblances being
further promoted by the failure to ulcerate and the
assumption of an intense purple hue in the course of
gradual involution. They differed however, in their

longer duration, in their association with typical lesions
of papulonecrotic tuberculides (*some of which failed
to show the characteristic central necrosis*) and in the
presence of chronic active tuberculosis of the lymph
gland variety. It is possible that this type may be
more properly labeled as papulonecrotic tuberculide
with atypical lesions on the lower extremities, the
physical attributes of the latter being markedly modi-
fied by location. [*Italics added.*]

Peculiarly enough, these 3 cases concerned women of
middle age and beyond, all had subfebrile temperatures
during some part of the course, and all recovered, at least
temporarily. Two of them were followed for many
months, of these one had a draining sinus in the neck,
which apparently healed after the use of ultraviolet and
x-ray radiation, though this required a long time. How-
ever, almost one year later, I ascertained that the cuta-
neous lesions had recurred on several occasions. In this
instance, also, the necrotic centers were so small and su-
perficial as to create the effect of dried vesicles, and as the
lesions were situated on the dorsums of the hands and
the extensor aspects of all the limbs, and as they recurred
in many crops, the eruption strikingly resembled Hebra's
erythema multiforme exudativum. The postmortem find-
ings in Case 24111 indicated strongly that this dermatosis
represents the result of a tuberculous infection disseminat-
ing in the secondary stage of Ranke and that this va-
riety of generalizing tuberculosis is not rare in persons of
advanced age. About two weeks ago I encountered still
another instance showing similar manifestations in a
woman some thirty years of age. Whether the eruption
is peculiar to women afflicted with childhood tuberculo-
sis it is difficult to state. The predilection for the lower
limbs and the painful attribute of the lesions are ex-
plained, at least partly, by the impaired circulation com-
monly observed in the lower limbs, notably in this sex.
Had the patient in Case 24111 recovered, there would un-
doubtedly have lingered in the minds of some observers
the impression that the case was an example of rheu-
matic fever with erythema nodosum.

Case 24092 (218 393-396, 1938) presents more impor-
tant implications. I am less concerned with the nonde-
script eruption seen in this case of miliary tuberculosis
than with the suggested diagnosis of systemic lupus erythe-
matosus and the comments made on the basis of the pa-
per published by Baehr, Klemperer and Schiffman (*Tr. A.
Am. Physicians* 50 139-155, 1935). As internists are likely
to derive their information from this article, and as this
condition and certain probably related syndromes appear
to be more common than has been hitherto suspected, it
seems pertinent to note that there are many controversial
points in this connection. For the present, I shall con-
fine myself to a brief discussion of the following funda-
mental subjects.

1 *The question of age and sex* Although systemic
lupus erythematosus most commonly affects young women,
it is by no means restricted to this group (*Arch. Dermat.*
& Syph 36 729-757, 1937). The condition is often ob-
served in girls, in women of more or less advanced age,
and occasionally in males (children and adults). In the
past few weeks, for example, I have seen 2 cases of the
disease in boys one of these came to necropsy, and the
other is still hospitalized. Several months ago I encoun-
tered an example of the condition in a man who died
postmortem examination was not performed.

2 *The question of atrophy in the cutaneous lesions*
Baehr, Klemperer and Schiffman stated that none of them
[the patients] ever had chronic discoid or atrophic le

sions,' a declaration based on an incomplete study of charts, insufficient material and failure to correlate the dermatological aspects. The probable reason why fewer instances of the atrophic form of this disease show an acute exacerbation at the present time will be mentioned under Point 3. It suffices to state (1) that atrophy in the dermatological sense is not an absolute criterion for the diagnosis of lupus erythematosus, (2) that "superficial" lupus erythematosus with constitutional symptoms may be later replaced by atrophic lesions in the skin, and (3) that there is no precise relation in all cases between the extent and attributes of the eruption and the severity of the systemic reaction—the fading of the cutaneous lesions is by no means an evidence of cure in the disease (Arch Dermat. & Syph 36 729-757, 1937, Brit. J. Dermat. 49 221-237, 1937).

3 *The question of a "new disease" and of photosensitivity* Baehr, Klemperer and Schiffrin attempted to establish a new disease, separating it from the cases "with the chronic discoid type of lesion and those with the essentially photosensitive skin" because 'they [the latter two] present a totally different clinical picture, are not of themselves fatal, and, in our opinion, represent different diseases.' What they meant by the cases "with the essentially photosensitive skin" is not made clear in their publication. It is common knowledge that chronic discoid lupus erythematosus may, in many instances, undergo dissemination following exposure to sun and ultraviolet radiation. Painful experience has shown that this is one of the diseases in which these two factors should be avoided, and the diffusion of this knowledge is one of the probable reasons for the lessened incidence of acute exacerbations in such instances. In many beauty parlors and elsewhere it is a current fad to apply ultraviolet radiation indiscriminately for the purpose of creating a "Palm Beach effect", this dangerous practice should be condemned unequivocally by the medical profession.

Baehr, Klemperer and Schiffrin remarked that 'it should be emphasized that none of our patients had previously shown any evidences of photosensitivity. With this statement I am obliged to disagree on the basis of personal observations made in many of the cases reported by them. In several instances I was able to ascertain that these patients were well aware of reactions following exposure to sun (severe headache, burns of an intensity out of all proportion to the degree of exposure, and so forth). In some cases the subject may feel sick after such exposure, without being able to define the symptoms precisely. To elicit this information it is essential, first, to make a correct diagnosis, and, secondly, to interrogate the patient carefully, with particular reference to a previous history of intolerance to sun. Only several weeks ago I had the privilege of observing another case in a girl who gave an excellent history of sensitivity to the rays of the sun, yet, this information was not recorded in the chart. A study based chiefly or entirely on chart work may therefore be defective in data of this sort. The subject of porphyria is still unclarified, and as the chemistry of these substances is in a state of flux, the topic need only be mentioned in passing.

There is, however, one more important point that promises to be of great interest, this concerns observations made by Turner (New Eng. J. Med. 216 158-161, 1937). He described the features of 3 cases of dermatomyositis, in 2 of which there was a history of sensitivity to sunlight. It is my intention, in another publication, to report a large group of personally observed cases showing transitions between systemic lupus erythematosus and dermatomyositis, and to indicate their essential affinities as well as their differences.

4 *The question of tuberculosis* Generalized lymphadenopathy, both clinically and at necropsy, is often encountered in systemic lupus erythematosus, and it represents a part of the disease. In some cases it may be a conspicuous feature. In occasional instances the nodes may break down, and this is often erroneously attributed to tuberculosis. In 1933 I stated that there were many cases in which necrotic foci had been found post mortem in these structures and in which minute anatomical study had revealed no evidence of tuberculosis (Arch. Dermat. & Syph. 28 765-779, 1933). The coincidental relation between these diseases was also stressed in another publication (Arch. Dermat. & Syph. 34 124-126, 1936). Later it was noted that such findings represent a peculiar feature in systemic lupus erythematosus (Arch. Dermat. & Syph. 36 729-757, 1937). Such necrotic foci may also be found in the spleen and other organs, and in the absence of microscopic study, these may be regarded as evidence of tuberculosis. It is to be emphasized that neither disease excludes the other and that, therefore, their occasional coincidence is not surprising.

Systemic lupus erythematosus is a disease known to dermatologists for a long time—actually over fifty years. One of the major contributions was the demarcation of atypical verrucous endocarditis (Libman and Sacks [Arch. Int. Med. 33 701-737, 1924]). Shortly before his death, Dr. Gross permitted me to read a paper in which he described distinctive microscopic features in this type of endocarditis, it is hoped that this article will be published posthumously. There is need for co-operation among the many specialists who observe this disease and related syndromes, for only by this means will it be possible to correlate knowledge.

ANNUAL REGISTRATION

To the Editor In his letter to the *Journal* of April 14, Dr. Stephen Rushmore gives me credit for the defeat of annual registration which is altogether out of proportion to the work done by me. He fails to give credit to many of the district medical societies, as well as to the Council of the Massachusetts Medical Society, which has voiced opposition annually for the past three years. The presidents of the Society as well as the chairmen and members of the Committee on State and National Legislation, the legislative counsel and many others also deserve recognition. It is unreasonable to think that the Council for three years would voice its opposition without good reason therefor. The Board of Registration in Medicine has recommended three bills to the Legislature. In 1936 it recommended a bill on which the *Journal* editorially commented, in part

The real intent of the bill is slightly different from the obvious purpose which appears on superficial examination.

It was defeated.

In 1937 the Board recommended a bill that would have compelled the Board to publish annually for wide distribution lists of all registered physicians with their self-named specialties. It was defeated.

In 1938 the Board recommended the least harmful of the three bills, but many considered it merely an entering wedge for future amendments until the Board could gain the powers sought in the 1936 bill. It has already been referred to the next General Court.

The *Journal of the American Medical Association* on April 10, 1937, reported a discussion following a paper,

"Some Problems in Medical Licensure in Massachusetts, which was read before the Federation of State Medical Boards held in Chicago. In it, Dr. Rushmore is reported to have said:

The Board has again this year introduced a bill providing for annual registration of physicians. They introduced a bill last year and the Massachusetts state society opposed it. I think there is a fair chance that the society will oppose it again this year. Then the question will come up as to whether it is wise to drive it through over their opposition or whether it is better to wait another year and try to educate the society. As you can understand from our remarks, the society needs educating.

In his recent letter of April 14, he says:

The Board has made no drive. Such fight, drive, campaign or other effort is outside the province of the Board.

My interest in the problem of annual registration, which is wholly impersonal, was aroused by the editorial in the *Journal* on December 12, 1935, when the original drive for annual registration was started. This carefully written editorial, which has never been repudiated, would seem to be reliable as the secretary of the Board of Registration in Medicine is also a member of the editorial staff of the *Journal*. The editorial stated:

The real intent of the bill is to provide information as to which physicians the State now regards as qualified to practice medicine.

The *now* in the above statement seems to mean that the Board hoped to make a special list of its own choosing, or that it planned to eliminate those it thought not qualified, although already registered. Giving unnecessary powers to unknown appointees of unknown governors is apparently becoming less popular.

On March 19, 1936, February 12, 1937, and March 17, 1938, I have published letters on annual registration in the *Journal* and I believe them to be accurate, concise and strictly confined to the subject discussed. I deeply regret the necessity of making this reply.

RICHARD DUTTON, M.D.

Wakefield, Massachusetts.

HOSPITAL DAY AT THE NEW ENGLAND SANITARIUM AND HOSPITAL

To the Editor: Since the idea of a National Hospital Day was instituted back in the early twenties there has been a growing interest throughout the hospital field. Each year has found a larger number of hospitals taking part in the celebration and opening their doors to the public. This effort, perhaps as much as any other one factor, has served to educate the public in modern hospital procedure and facilities. Then, too, Hospital Day programs, as they have been carried on in many institutions, have been arranged so as to educate the public in sickness prevention, health habits and simple methods of home treatment.

Our institution here on the outskirts of Boston in Middlesex Fells Reservation has made education the theme of our Hospital-Day programs. We believe that it is the function of the modern medical institution, not only to treat those who come to them for care, but to educate the public in ways and means to preserve health.

Last year we were able so to publicize our activities that the Hospital Day Committee of the American Hospital Association awarded us the Parke, Davis Trophy for the

best Hospital Day publicity program of all hospitals in America.

This year we are again attempting to present such an educational program that the thousands of visitors who come here on that day will go away feeling that they have a fairly adequate idea of what the modern hospital can do for them in case of sickness, and also with a somewhat intelligent conception of how to maintain their health.

Our program for the day includes:

Morning chapel program on front lawn around flag-pole; nurses repeat Florence Nightingale pledge, devotional service, flag raising, talk by medical superintendent.

Tour of institution with educational displays in each department.

Speaker—Lieutenant Governor Francis E. Kelly, of Massachusetts.

Gymnasium exhibits: premature infant in incubator, portable x-ray on accident cases, portable diathermy on pneumonia cases, deep therapy lamp for treating surgical wounds, Balkan frame supporting traction for fractured leg, metabolism apparatus in use, electrocardiograph in use, oxygen tent for bronchitis patients, croup tent for bronchitis patients, hydrotherapy cart for bed treatments and health literature booth—Metropolitan Life Insurance Co. and John Hancock Mutual Life Insurance Co.

Dietetic booth.

Baby party and clinic.

Tree planting in memory of Matthew O. Foley, founder of National Hospital Day.

Awarding of prize to nurse exhibiting best health record last year.

The above program will be supplemented by talks in churches, clubs and public gatherings, radio talks, newspaper publicity, postcard and letter invitations, posters and stickers as provided by the American Hospital Association, movie trailers and periodicals.

If all the hospitals in our land put forth a concerted effort to enlighten the public on that day about what the hospital is able to do for them, it would be a mighty factor in breaking down any prejudice or misunderstanding that may exist in their communities.

PAUL R. CONE, *Chairman*

Hospital Day Committee.

New England Sanitarium and Hospital,
Stoneham, Massachusetts.

REPORTS OF MEETINGS

NEW ENGLAND HEART ASSOCIATION

The regular monthly meeting of the New England Heart Association was held at the Beth Israel Hospital on March 28. The following program was presented:

THE INCIDENCE OF THE CRITERIA OF ALLERGY IN CASES OF CARDIAC ASTHMA. Hyman Morrison, M.D.

Though it is now generally accepted that cardiac asthma, or paroxysmal nocturnal dyspnea, is brought about by left ventricular failure, this disease syndrome, especially when it is accompanied by wheezing, simulates so closely an attack of bronchial asthma that there are some clinicians who consider the two to be related genetically. To gain a better knowledge of this relation, cases of cardiac asthma, some with wheezing and others without, were studied with the collaboration of Dr. Abraham Colmes in the light of the criteria of allergy. The history of the incidence of allergy in the family and in the past life of the patient was obtained and other allergic manifestations and food peculiarities were determined, skin tests were done, and the blood studied for eosinophilia. The accompanying

table sums up these findings in the two groups compared with a group of control cases and with another of bronchial asthma with heart disease.

	NUMBER OF CASES	FAMILY HISTORY OF ALLERGY	PAST HISTORY OF ALLERGY	OTHER ALLERGIC MANIFESTATIONS	FOOD PECULIARITIES	POSITIVE SKIN TESTS	EQUINOPIHILIA OF 5+ %
Cardiac asthma with wheezing	11	1	0	1	6	6	2
Paroxysmal dyspnea with angina or edema without wheezing	11	1	0	2	2	6	1
Bronchial asthma with heart disease	48	21				39	14
Miscellaneous control cases	20	3	3	2	7	14	1

It was stressed that these figures do not justify the conclusion that cardiac asthma with wheezing can occur only in individuals who are allergic. Furthermore, it was questioned whether it is justifiable to consider wheezing, or musical rales, as pathognomonic of bronchospasm or allergy, especially as this sign is encountered in a number of diverse conditions such as acute and chronic bronchitis, pulmonary emphysema and bronchial obstruction due to foreign bodies or tumors, internal or external.

It is hoped that further data will be gathered to clarify this problem.

THE SIGNIFICANCE OF ELECTROCARDIOGRAPHIC CHANGES ASSOCIATED WITH ATTACKS OF ANGINA PECTORIS Joseph E. Riseman, M.D.

Continuous electrocardiographic tracings taken during exercise in 20 patients with angina pectoris show that the characteristic S-T changes associated with attacks of pain become evident long before pain develops and that the disappearance of these changes bears no constant relation to the disappearance of pain.

Electrocardiographic changes during attacks induced by breathing approximately 10 per cent oxygen while at rest were identical with those observed in the same patients during attacks induced by exercise.

The amount of work which patients could perform before developing an attack of angina pectoris could be increased appreciably by having them breathe pure oxygen continuously both before and during exertion. The characteristic S-T changes induced by a given small amount of exercise could be prevented by having the patient breathe oxygen before and during exertion.

It is apparent, therefore, that the electrocardiographic changes observed during paroxysms of angina pectoris are due to myocardial anoxia.

THE RELATION OF BLOOD PIGMENT METABOLISM TO THE CHANGES IN BLOOD VOLUME IN CONGESTIVE HEART FAILURE John Waller, M.D.

An increased plasma bilirubin is always demonstrable in chronic congestive heart failure. The anoxemia has been proved to impair the excretory power of the liver. Since Gibson and Evans have demonstrated a definite decrease in total blood volume in the recovery from congestive failure, an attempt to trace the fate of the red blood cells was made. Total urinary and fecal blood pigments, as urobilinogen, were determined, and the blood volume estimated by the method of Gregerson, Gibson and Stead. In the present study patients with severe chronic congestive failure were followed. It was found that a decrease

in the total circulating red blood-cell volume was, in every instance, accompanied by a marked increase in the urinary and fecal pigment excretion. The reticulocytes, as previously described, were found to be increased at the height of failure and to return to normal as the patient improved. The red-cell fragility to saline solution was definitely increased at the height of failure, beginning at 0.56 per cent saline, and also decreased toward normal as the clinical condition improved. The percentage of the total urobilinogen in the urine was related to the duration of the congestive failure, and presumably the degree of liver dysfunction, the greater the duration of failure, the larger the urinary fraction of urobilinogen.

It was concluded that the finding of increased blood volume in congestive failure, with return toward normal accompanying clinical improvement, had been confirmed and that information had been acquired regarding the mechanism of disposal of the red cells.

THE EFFECT OF DIGITALIS IN PARTIAL HEART BLOCK. Mark D. Altschule, M.D.

Considerable difference of opinion exists concerning the advisability of using digitalis in patients with partial heart block. Some authors feel that its use is contraindicated because of the danger of the development of complete block. Nineteen patients were studied, 6 had rheumatic heart disease and the others had coronary arterial disease. In all, the P-R interval was prolonged, and in addition, 2 had frequent dropped beats and alternating 2:1 and 1:1 response. Digitalis was administered in doses calculated in the usual manner from the body weight. Electrocardiograms were made before and after digitalization. In no case did an increase in P-R interval or the development of a higher grade of block occur. The only changes noted in the electrocardiogram were typical changes in the T wave due to the administration of digitalis, and in some cases, slowing of the heart. It was concluded that digitalis in the usual therapeutic dosage can be given when indicated in patients with partial heart block without precipitating complete heart block.

THE CLINICAL AND PATHOLOGIC MANIFESTATIONS OF CORONARY ARTERIAL DISEASE AS DISCLOSED BY INJECTION PLUS DISSECTION STUDIES David Davis, M.D.

Using the method developed by Schlesinger, the condition of the coronary arteries was studied in 89 hearts to determine the anatomic basis of angina pectoris and of coronary thrombosis.

Of the 89 patients there were 11 with a history of un complicated angina pectoris, months to years in duration. All these hearts showed extensive coronary artery disease with complete occlusion of one or more of the major coronary branches. In all, there also was extensive disease involving one or more of the remaining major branches, so that an area formerly supplied by an occluded vessel was found to be receiving blood through anastomotic channels from other substituting arteries, which themselves had become diseased and narrowed by atheromatous processes.

In another group of 11 patients of approximately the same age who had never had angina pectoris, and 8 of whom died of non-cardiac causes, the hearts also showed complete occlusion of one or more of the major coronary branches. Since patients with angina pectoris almost invariably show coronary disease, the members of this second group were likely candidates for angina pectoris. They had not had any anginal symptoms presumably because

the slow occlusion of a major coronary branch often is silent, on account of the gradual development of adequate anastomotic circulation from the neighboring arteries. Thus when symptoms of angina are first experienced, it appears probable that one or more arterial occlusions have already occurred, the symptoms of angina are due to ischemia resulting from disease in and failure of the previously adequate anastomotic circulation. This apparently was the mechanism in the 11 patients with angina pectoris.

In a third group of 11 patients, who presented the clinical syndrome of coronary thrombosis, the hearts of 9 showed essentially the same mechanism. In these, there was extensive disease or occlusion in two or more major coronary branches, and either definite evidence of infarction was found or a fresh thrombus was revealed without histologic evidence of infarction. Under the latter circumstances, sufficient time may not have elapsed before death to reveal pathological evidence of infarction. It would appear that the extent of arteriosclerotic involvement in patients with coronary thrombosis and cardiac infarction is not clearly different from that found in those with angina pectoris without infarction. The occurrence of cardiac infarction would seem to be due, in large part to the rapidity with which thrombosis and occlusions occur. If sufficient time is not available for the establishment of an adequate anastomotic circulation, then infarction will occur.

THE BREATH HOLDING TEST. A SIMPLE STANDARD STIMULUS OF BLOOD PRESSURE. David Ayman, M.D.

One of the outstanding characteristics of essential hypertension is the variability of the blood pressure under the influence of different stimuli such as excitement, pain and cold. The variability of the blood pressure has been investigated by many men who have attempted to apply standard methods of stimulating the blood pressure. Most of these methods have not been adopted for clinical study due to their lack of simplicity.

In 1932, Hines and Brown introduced a simple standard stimulus, consisting of placing the hand, up to the wrist, in cold water, the temperature of which is maintained at 4°C. The hand is kept in the ice water for sixty seconds and the reading of the blood pressure then made. The test is carried out only after the subject has rested and after a basal level of blood pressure has been secured. Since their first paper, Hines and Brown have reported results in 571 subjects. They found that their subjects with normal blood pressure could be divided into two groups, hypo-reactors and hyper-reactors. Subjects with definite essential hypertension showed hyper reactions. In a subsequent study of families, Hines showed that the hyper reaction occurred only in families in which one or both parents had hypertension or a hyper reaction. Where both parents had normal blood pressure and had a hypo-reaction, the children all had hypo-reactions and normal blood pressures. Further, when studying the incidence of the hereditary factor in hypo-reactors and hyper-reactors and patients with essential hypertension, Hines and Brown found that 84.6 per cent of the hyper-reactors and 86.6 per cent of the subjects with essential hypertension had a family history of cardiovascular disease, while only 17.2 per cent of the hypo-reactors had such a positive family history.

The present study involved, first, a repetition of Hines and Brown's cold pressor test. In 313 cold tests, the results compared closely with theirs. Secondly, in order to devise an even simpler pressor test, the breath holding test

was developed. In this test, the subject closes the nose tightly with his fingers, shuts his mouth tightly, and holds his breath in quiet expiration. The systolic blood pressure reading is made at the end of 20 seconds. The subject is then allowed to breathe and after another basal blood-pressure level is obtained, the test is repeated for the diastolic blood pressure reading. The results of 596 breath-holding tests showed a close similarity to the results of the cold-pressor test carried out in the same patient. Whatever the significance of standard pressor tests may be, the breath holding test is simpler, more rapid and as accurate as the cold-pressor test.

CARDIAC CIRRHOSIS. Herrman L. Blumgart, M.D.

Confronted in certain cases of congestive failure with the question of cardiac cirrhosis and with the paucity of pertinent available information, an investigation was undertaken of an unselected series of consecutive cases in order to learn (1) the incidence of hepatic fibrosis in all cases with congestive heart failure, (2) the types and degrees of such hepatic fibrosis found in cases of congestive failure, (3) the differences between these findings and those found in the cases without congestive failure, and (4) the incidence of hepatic fibrosis due to congestive failure compared to that due to biliary tract disease.

Of patients dying with congestive heart failure, approximately a third showed increased hepatic fibrous tissue, which was twice the general incidence of the 2000 consecutive autopsies. The causal significance of chronic passive congestion in the production of hepatic cirrhosis was emphasized by the increasing incidence and severity of the cirrhosis with increasing duration of congestive heart failure. The only type of cirrhosis peculiar to cardiac decompensation was central cirrhosis.

Of particular interest was the finding of Laennec's cirrhosis in 22 per cent of the patients with congestive failure as compared with 9 per cent in the remainder of the series. Central and portal cirrhotoses coexisted in 18 cases and were associated with congestive heart failure in every case, with but one exception. This suggests that chronic passive congestion, with resulting anoxemia, may increase the susceptibility of the hepatic tissue to injury in the portal as well as in the central areas.

From the foregoing evidence, the meaning of cardiac cirrhosis is clarified. In the morphologic sense of increased fibrosis being due to chronic passive congestion, one may state that the majority of patients who have suffered from even mild congestive failure for nine months or more show increased fibrosis of the liver, the cirrhosis being usually either central or portal in type.

Whether cardiac cirrhosis in the clinical sense of increased fibrosis causing clinical manifestations is present or not must be based on clinical evidence. This was discussed in the light of the evidence gained from study of the series of patients.

NEW ENGLAND SOCIETY OF PSYCHIATRY

The following men were elected as officers of the New England Society of Psychiatry for the year 1938 at its annual meeting which was held at the Neuro-Psychiatric Institute of the Hartford Retreat, Hartford, Connecticut on April 26: president, Dr. Harlan L. Paine, superintendent of Grafton State Hospital, North Grafton; vice president, Dr. Forrest Tyson, superintendent of Augusta State Hospital, Augusta, Maine; secretary-treasurer, Dr. George A. Elliott, assistant superintendent, Connecticut State Hospital, Middletown; councilors, Dr. Chester Waterman, superintendent of Norwich State

Hospital, Norwich, Connecticut, and Dr Roy D Halloran, superintendent of Metropolitan State Hospital, Waltham, Massachusetts

Dr Louis Cohen of the Research Department of the Worcester State Hospital, Worcester, presented a very interesting paper on "Metrazol Treatment in Schizophrenia."

GEORGE A ELLIOTT, *Secretary Treasurer*

BROOKFIELD MEDICAL CLUB

The Brookfield Medical Club held its 559th meeting at Ye Olde Tavern, West Brookfield, on April 20

Dr C J Huyck, of West Brookfield, was host, and Dr Gardner Cobb was guest speaker. He spoke on "Observations in Pediatrics." Discussion followed.

Dr James Murphy, of Palmer, will be host at the next meeting which will be held on Wednesday, May 18

JOHN R. FOWLER, M.D., *Secretary*

HOSPITAL COUNCIL OF BOSTON

At the annual meeting of the Hospital Council of Boston, which is composed of twenty four hospitals in Greater Boston, Frank E. Wing, director of the Boston Dispensary, was chosen president, and Dr Charles F Wilinsky, secretary treasurer. Rev Thomas J Brennan, superintendent of St. Elizabeth's Hospital, and Dr James W Manary, director of the Boston City Hospital, were elected to the executive committee.

In the annual report, presented by Dr Joseph B Howland, the need for more free and part time evening clinics was stressed. During 1937, admissions of member hospitals increased 47 per cent, hospital days 57 per cent and outpatient visits 44 per cent over the figures for 1936

NOTICES

BOSTON SOCIETY FOR THE ADVANCEMENT OF GASTROENTEROLOGY

The next meeting of the Boston Society for the Advancement of Gastroenterology will be held in the Cheever Amphitheater of the Boston City Hospital, on Wednesday, May 18, at 12 o'clock noon.

Dr Martin E. Rehfuess, clinical professor of medicine, Jefferson Medical School, Philadelphia, will lecture on "The Gall Bladder Problem."

C W McCLURE, M.D., *Secretary*

BOSTON CITY HOSPITAL

There will be a monthly conference of clinical pathology at the Boston City Hospital, on Wednesday, May 11, at 12 o'clock noon, in the Pathological Amphitheater

JOSEPH E HALLISEY, M.D.,
Secretary Medical Staff

SUMMER COURSE IN FORENSIC MEDICINE

The annual postgraduate course in forensic medicine in the New York University College of Medicine will be repeated again during June of this year

Intended chiefly for coroners, coroners physicians, medical examiners and other physicians interested in medico-legal work, the course will consist of lectures and practical

instruction in the necropsy rooms and laboratories of the chief medical examiners of New York City and Essex County, New Jersey

Dr John H. Mulholland, assistant dean of the college, is in charge of registration for the course.

POSTGRADUATE COURSES IN PARIS

Word has been received from L'Association pour le Développement des Relations Médicales that a series of short courses (in English) on medical subjects will be given in Paris during the last week in June and the first two weeks in July. Each course will consist of six lectures or demonstrations in the mornings or afternoons, or both, of a given week. The subjects to be covered are cardiology, ophthalmology, gynecology, endocrinology, pediatrics, neuropsychiatry, dermatology, histology, physiology, ureteropyelography and abdominal surgery. They will be given by members of the Faculté de Médecine. The charge for each of the morning or afternoon courses is 300 Fr. fr., and for both 500 Fr. fr.

Further information may be obtained by writing to Bureau de l'A.D.R.M., Salle Beclard, Faculté de Médecine, Paris, VIe.

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning from ten to twelve-thirty there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. All kinds of tumors are seen, discussed, and when indicated, treated with radium and high voltage x-ray.

Physicians are welcome to visit this clinic and bring patients to the clinic for diagnosis.

NATIONAL HOSPITAL DAY

The New England Hospital Association and the Massachusetts Hospital Association are working together with the National Committee of the American Hospital Association in the observance of National Hospital Day, Thursday, May 12.

Many hospitals are making extensive plans in the observance of this day. Hospitals throughout New England will have "open house" in order that former patients and friends may visit the hospital to see the latest scientific equipment and apparatus used in the modern treatment of patients.

All members of medical societies are urged to cooperate with hospital administrators by taking part in clinical demonstrations and lectures that may be of interest to the lay public.

Time has been reserved on the air for May 10 and 11, and medical men have been secured to talk on "Our Hospitals."

JOSEPH P. LEONE, M.D.,
National Hospital Day Chairman,
Massachusetts Hospital Association

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, May 17, at 12 o'clock noon.

Dr Abraham Colmes will speak on "Simplifying the Approach to Clinical Allergy."

All physicians are cordially invited to attend.

JOHN B. HALL, M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, MAY 9

TUESDAY MAY 10

- 9-10 a. m. Boston Dispensary Medical History of Appendicitis
Dr Reginald Fitz
- 10 a. m. 12-30 p. m. Tumor clinic. Boston Dispensary

WEDNESDAY MAY 11

- 9-10 a. m. Boston Dispensary Hospital case presentation Dr S J Thannhauser
- 1 p. m. Clinicopathological conference. Children's Hospital amphitheater
- 1 p. m. Boston City Hospital Conference of Clinical Pathology Pathological amphitheater

THURSDAY MAY 12

- National Hospital Day
- 9-10 a. m. Boston Dispensary Social service case presentation Mrs. H B Hooker and Miss E. Grundy

FRIDAY MAY 13

- 9-10 a. m. Boston Dispensary The Course of Heart Disease and the Precipitating Factors of Heart Failure. Dr C. Sidney Burwell
- 10 a. m. 12-30 p. m. Tumor clinic Boston Dispensary
- 1 p. m. Clinical meeting of the Children's Medical Service Massachusetts General Hospital Eber Dome.

SATURDAY MAY 14

- 9-10 a. m. Boston Dispensary Hospital case presentation Dr S J Thannhauser
- 10 a. m. 12 m. Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A. Christian

*Open to the medical profession

- MAY 5—Faulkner Hospital clinicopathological conference 5 p. m.
- MAY 11—Boston City Hospital Conference on Clinical Pathology Page 4

BOOKS RECEIVED FOR REVIEW

Modern Dietary Treatment Margery Abrahams and Elsie M Widdowson. 328 pp Baltimore William Wood & Company, 1937 \$3.25

Treatment of Some Chronic and Incurable Diseases A T Todd. 203 pp Baltimore William Wood & Company, 1937 \$3.00

The Hair and Scalp A clinical study (with a chapter on hirsuties) Agnes Savill Second edition. 309 pp Baltimore William Wood & Company, 1937 \$4.75

Wheeler and Jack's Handbook of Medicine Revised by John Henderson. Tenth edition. 703 pp Baltimore William Wood & Company, 1937 \$4.00

Medicine for Nurses W Gordon Sears Second edition. 435 pp Baltimore William Wood & Company, 1937 \$3.25

Tuberculosis Among Children and Young Adults J Arthur Myers Second edition. 401 pp Springfield, Illinois, and Baltimore Charles C Thomas, 1938 \$4.50

Pharmaceutical Latin For pharmaceutical medical dental and veterinary students and practitioners Jacob S Dorfman Second edition 146 pp Philadelphia Lea & Febiger, 1938 \$2.00

Medical Writing The technique and the art Morris Fishbein, with the assistance of Jewel F Whelan. 212 pp Chicago Press of the American Medical Association, 1938 \$1.50

Vade Mecum of Medical Treatment W Gordon Sears. 368 pp Baltimore William Wood & Company, 1937 \$4.00

Synopsis of Obstetrics and Gynaecology Aleck W Bourne. Seventh edition. 452 pp Baltimore William Wood & Company, 1937 \$4.00

Diseases of the Skin A manual for students and practitioners Robert M MacKenna Revised and enlarged by Robert W B MacKenna Fourth edition 557 pp Baltimore William Wood & Company, 1937 \$7.00

BOOK REVIEWS

X Rays and Radium in the Treatment of Diseases of the Skin George M MacKee. Third edition, thoroughly revised. 830 pp Philadelphia Lea & Febiger, 1938 \$10.00

This book covers very thoroughly the therapy of skin diseases by x ray and radium. Two previous editions have been published, and the present one has been largely rewritten in view of the progress which has been made in this field. The author has contributed largely to this progress and in this edition has enlisted the collaboration of other authorities in various phases of the subject. The physics of the radiation used in skin diseases has been brought up to date and amplified by Dr Edith Qumby. The matter of dosage and the measurement of dosage, together with the factors governing it, are emphasized. The

effects of x rays, both biologic and biochemical, are reviewed in considerable detail, with a very characteristic picture being drawn of the pathologic effects of radiation. Almost half the book is devoted to the use of radiation in the treatment of various dermatoses. Emphasis is placed on the diseases in which radiation is an important factor, and numerous excellent clinical photographs before and after treatment, from the author's large collection, are included. The many diagrams and tables in the earlier part of the book and the numerous references at the end of each chapter make it an almost indispensable book to the physician treating skin disease. A final chapter on the medicolegal aspects rounds out the book. There is no comparable book in English on this subject.

A Textbook of Hematology William Wagner 395 pp
Philadelphia P Blakiston's Son & Co, Inc, 1938
\$4.50

Following a long dearth in English texts on hematology, there has appeared a series of books, large and small, dealing with this subject. One of these is the book by Wagner, a Canadian pathologist, whose primary purpose is to write for the practicing physician. Despite its apparent simplicity, the subject is quite well covered, although not infrequently one is struck by the somewhat uncritical view which the author takes of his quoted literature. This is in all probability due to his relative unfamiliarity with the clinical problems of the hematologist. Hematology has gradually been taken over by the clinician, and rightly so, since hematological problems are so completely intertwined with those of general medicine.

The book suffers from very amateurishly made colored plates, which are poorly lithographed, and from atrociously executed oil immersion photomicrographs of blood smears. The descriptions of laboratory methods are frequently slipshod, as in the section on the estimation of cell volume where the recommendation is made that "well shaken oxalated blood" be used without any statement as to the type or percentage of oxalate, the centrifuge speed, necessity for packing, and so forth. No mention is made of the widely used mean corpuscular volume, or of the coverslip method for making blood smears. Osgood and Wilhelm's method for counting reticulocytes is featured (this gives counts much too high), and counting "the number of reticulocytes amongst 200-300 red cells" is advised. Only the puncture method of performing the bone marrow biopsy is mentioned, no statement regarding the much more accurate trephine method being made. There is a good section on the iron-deficiency anemias, and in general the discussion on the anemias is good. Again, some of this is invalidated by lack of clinical experience, as in the statements that in the majority of cases of pernicious anemia the neurological examination yields negative results and that the injection of 1 cc. of liver extract every three or four weeks is sufficient for maintenance of the proper red-cell level. Both of these statements are contrary to the reviewer's experience. There are many errors in spelling of authors' names, both in the text and in the bibliography. There is no mention of the neoplasms of the white cells or of Hodgkin's disease, but seven pages are given to a discussion of the very rare condition of osteosclerosis involving the marrow, apparently because the author has seen a case.

The book, although it has much to commend it in simplicity of style and good general discussion, loses considerably in value because of numerous defects which may possibly be corrected in a future edition.

A Method of Anatomy Descriptive and deductive J C. Boileau Grant. 650 pp Baltimore William Wood & Company, 1937 \$6.00

It is refreshing to examine a book of anatomy with the arresting title of "a method of anatomy." The use of the phrase 'descriptive and deductive' as a subtitle gives one the impression that the primary purpose of the book is not alone the presentation of anatomic facts, but also the consideration of pedagogic principles which help give understanding to these facts. In the preface the author calls attention to the fact that the purpose is to lead the student to approach the subject from the point of view of studying anatomic facts in their mutual relations and of apprehending the underlying principles involved and the *raison d'être* of such relations. By dipping into embryology, comparative anatomy, clinical medicine and surgery, and cognate sciences, the author has succeeded admirably in his task to elucidate what would otherwise be dry facts.

The logical clarity of exposition and the terse, clear style of the book strike one at every page. One is impressed with the 564 accurate diagrammatic line drawings based on carefully dissected material. The format with its 750 large double-column pages will, it seems, make a strong appeal to the student. An interesting feature which calls for special mention is the discussion of "Key Positions" in the consideration of the various regions of the body. The terminology employed with few exceptions is the Birmingham Revision of the B N A.

It seems to the reviewer that a future edition would benefit by the introduction of radiographs, a brief discussion of the growth of the face, a figure showing the plan of the fetal circulation, a more complete account of the innervation of the joints, and a general consideration of the action of the muscles of the back. Although the author states that this book is not a dissecting guide, it would seem desirable to introduce more directions for dissection. No doubt such additions would have increased the size of the book appreciably, but this would not have been a disadvantage.

The author is to be congratulated upon his interesting treatment of the subject and will be rewarded by the strong appeal which this book is sure to make to students, physicians and surgeons.

Treatment in General Practice Harry Beckman Third edition 787 pp Philadelphia and London W B Saunders Company, 1938 \$10.00

This is the third edition of a book on treatment in general practice which has already gained considerable popularity among students and practitioners. It reflects in its simplicity of style and conciseness the author's long teaching experience in this field. Bits of history here and there are of additional interest.

The book lacks the usual chapter arrangement, and only one section, its first and largest, which deals with infectious diseases, has any definite order, topics appearing alphabetically. This means a loss of the natural sequence and proportionate importance of diseases expected in the conventional textbooks on medicine.

Another criticism is the author's modest consideration of himself as an author, he acknowledges as his sources over eight hundred items in the recent periodical literature, as listed with their authors in the bibliography. A textbook, especially one in therapeutics, should be an unqualified authority.

NUMBER 19

THE EFFECT OF IRRITANTS AND DRUGS AFFECTING THE AUTONOMIC NERVOUS SYSTEM UPON THE MUCOSA OF THE NORMAL RECTUM AND RECTOSIGMOID, WITH ESPECIAL REFERENCE TO 'MUCOUS COLITIS'

BENJAMIN V. WHITE, JR., M.D.,* AND CHESTER M. JONES, M.D.†

BOSTON

THIS investigation presents certain observations on the physiologic processes of the rectum and rectosigmoid, which may throw some light on those disorders of the colon apparently concerned with physiologic rather than anatomic abnormality. The changes observed are of two kinds: those affecting the appearance of the mucous membrane as observed through the sigmoidoscope, and those affecting the motility of the rectal wall.

Few studies of the rectal and colonic mucosa in response to the administration of drugs have appeared. Watts and Fulton¹ reported ulcerative lesions of the entire gastrointestinal tract, including the colon, following the production of artificial hypothalamic lesions in monkeys subsequently studied post mortem. The production of experimental gastrointestinal lesions by neurogenic stimulation has also been accomplished in a small percentage of cases by Keller, Hare and d'Amour.² These workers produced lesions in the region of the hypothalamus, and found that those cases in which hemorrhage into the ventricle had occurred or in which the lesions had been made in the anterior portion of the hypothalamic area most frequently showed gastrointestinal changes, hyperemia, hemorrhage and erosions. These alterations occurred in all parts of the gastrointestinal tract, including the colon, where the crests of the longitudinal folds showed hyperemia and in some cases frank hemorrhage.

Light, Bishop and Kendall³ consistently succeeded in producing ulceration of the stomach by the injection of 10 mg. of pilocarpine hydrochloride into the lateral ventricles of rabbits. Other parts of the gastrointestinal tract were not specifically examined. Banung and Hall⁴ has in the course of

other studies produced gastric ulcers and colonic lesions, probably through overstimulation of the parasympathetic nervous system. Larson and Barger⁵ and Barger⁶ introduced a technic of withdrawing an isolated loop of colon through the anterior abdominal wall. They were thus enabled to study quantitatively changes in mucus formation in the dog. They made studies following the use of different types of cathartics, and in one instance laid the extra-abdominal portion open, so that they could observe the surface in action. They found that the amount of mucus secreted during sleep was at a minimum, and that it was increased after defecation, and still more after defecation stimulated by catharsis. Saline cathartics produced the most normal mucus, castor oil the greatest quantity.

Forsell's⁷ barium relief method, which has been applied successfully to gastric roentgen study by Berg,⁸ has afforded a third avenue of approach to the study of the mucous membrane of the colon. Knothe,⁹ using this technic, made careful observations on the colon in normal and pathologic states, and believes it possible to recognize minimal mucosal changes, such as those seen in "mucous colitis," by this means. He has not, however, published any studies showing the effect of drugs on the colonic mucosa.

The electrically lighted sigmoidoscope affords another and more direct method of approaching the problem. Singer¹⁰ was among the early workers to describe the mucosal changes in mucous colitis which have been subsequently confirmed by other workers,¹¹ but this method has received little attention as a means of investigating the effect of drugs upon the normal mucosa.

The motility of the colon has been more fully observed. Bayliss and Starling¹² found that stimulation of the wall of the denervated small intestine was followed by contraction immediately above and relaxation immediately below the point of stimulation. He termed this phenomenon the "law of

*From the Medical and Psychiatric Clinics of the Massachusetts General Hospital and the Departments of Medicine and Diseases of the Nervous System of the Harvard Medical School.

†Jeffrey R. Harrison Fellow, Harvard Medical School.

Physician, Massachusetts General Hospital; assistant professor of medicine, Harvard Medical School.

the intestine" and believed that it was responsible for the forward movement of intestinal contents Cannon¹³ inferred from these and his own observations that this mechanism was at least partially responsible for the movement of fecal masses in the colon Hertz¹⁴ also seems to hold this view, stating that the rectum is normally empty, but that when a fecal bolus is allowed to drop into it from the rectosigmoid the defecation reflex is established Hertz describes a clinical type of constipation, "dyschesia," in which the rectum fills with fecal matter without exciting the defecation reflex, and he is at a loss to explain the syndrome because he finds that all normal rectums are insensible to thermal and painful stimuli Hines, Lueth and Ivy¹⁵ found in an unselected group of constipated persons that the rectum frequently failed to contract deeply when a balloon was inserted in the ampulla, whereas in the normal controls, deep, painful urges occurred

SELECTION OF SUBJECTS AND METHOD

In the present study, autonomic stimulating and inhibiting drugs and irritants were applied directly to the mucosa of the rectosigmoid, and in some instances were administered by mouth The mucous membrane was observed directly

All the control observations were made on male medical students between the ages of twenty-two and twenty-six All had essentially normal bowel habits, although 2 had been subject to changes related to emotional strain One (W.O.L.), a collegiate runner, had had diarrhea for three days before each race and constipation for three days afterward Another (S.T.) had suffered from emotional constipation The men were all in good health, and so far as is known were not suffering from any intercurrent disease A few observations on patients with "mucous colitis" are also reported

For observation of the colonic and rectal mucosa, an electrically lighted sigmoidoscope was employed Local applications were administered by small gauze pledgets held in the jaws of a modified bronchoscopic sponge holder Observations were made after evacuation, and in most cases at nine o'clock in the morning after breakfast, in order to obtain a consistent series of observations Except where specifically noted, preparatory enemas were avoided All observations were made with the subjects in the knee-chest position on a well-padded examining table

The following substances were applied locally on at least two occasions each, in the following concentrations benzedrine sulfate 1 per cent, epinephrine hydrochloride 0.1 per cent, physostigmine sulfate 1.0 per cent, atropine sulfate 0.5 per cent, pilocarpine hydrochloride 1 per cent, sodium

chloride 17 per cent, and oil of turpentine Acetyl- β -methylcholine chloride was administered by mouth in varying dosages, as were carbaminoylcholine chloride and benzedrine sulfate The irritant solutions, 17 per cent sodium chloride and turpentine, were kept in tightly stoppered bottles The solutions of drugs affecting the autonomic nervous system were freshly prepared from tablets or crystals

During the observation the mucosa was examined at intervals and the following characteristics were particularly noted

- 1 The degree of injection, the location in relation to the rectal valves, and to a certain extent the duration of the change were studied

- 2 The appearance of mucus, whether as a diffuse, glairy sheen, a frank accumulation of moist secretion or a dried coating partially adherent to the bowel wall, was observed

- 3 Attention was paid to the appearance of the veins and venules, which in some cases were widely engorged and elevated above the surface, but in others were obscured by generalized injection

- 4 Granularity and wrinkling of the mucosal surface, probably fundamentally different in their pathological significance, were found to be almost indistinguishable as seen through the sigmoidoscope. In observations upon the normal rectosigmoid it was assumed that roughness of the surface was produced by simple wrinkling of the mucous membrane In patients with "mucous colitis," however, this distinction was not relied upon

- 5 The presence or absence of changes in caliber of the intestine, the appearance or relaxation of spasm and the occurrence of rhythmic activity were observed When rhythmic activity followed the administration of irritants the exact number of contractions per minute was recorded

In most cases only one observation was made in a morning In a few cases irritants were applied at first in the sigmoid and then in the rectum, but owing to the possibility that the physiologic response was due to a summation of stimuli this procedure was discontinued In a number of cases atropine was applied after cholinergic drugs had been given, and its effect was also observed in patients with rectosigmoid spasm

Each irritant substance was applied on one occasion in the ampulla of the rectum between the middle and upper valves, and at another time in the sigmoid above the upper rectal valve, usually at the level of the left internal hypogastric artery. Sodium chloride was employed in a concentration of 17 per cent, because such a stock solution was used in the preparation of routine physiological saline and was available in the drug department It

Drawings by M. McLachlan

PLATE I

Appearance of Mucosa of Rectosigmoid under Experimental Conditions. A — control observation, B — two hours after standard soapuds enema, C — immediately after the application of 17 per cent sodium chloride solution locally, D — five minutes after 1 per cent pilocarpine hydrochloride locally, E — five minutes after the local application of 1 per cent physostigmine sulfate, F — fifteen minutes after the local application of 1 per cent physostigmine sulfate, G — after the oral administration of 1000 mg of acetyl beta methylcholine chloride per day for four days. All these observations were made on one subject (E. L. L.) and, with the exception of B, were made without preparation. H — lower sigmoid of a patient with advanced mucous colitis, without preparation. Note the generalized injection, the reduction in caliber and the granular rough surface, sheets of dried tenuous mucus, which were present, do not show in this field. The veins are not dilated at this stage of the disease.

proved to be highly irritant. Oil of turpentine was applied undiluted.

OBSERVATIONS

Below are recorded the observations made after the local administration of drugs to the mucosa of the rectosigmoid. In the case of the purely irritant substances the site of application is noted because of the difference in the response to applications in the rectal ampulla from that resulting from stimulation in the lower sigmoid. In the case of the autonomic stimulating or inhibiting substances the exact site of application is omitted in the interest of simplicity.

A colored drawing of the appearance of the rectosigmoid mucosa of a normal subject (E.L.L.) who had received no preparation for the examination is recorded in Plate 1*a*. A similar illustration (Plate 1*b*) shows the change in appearance two hours after a standard soapsuds enema (120 cc. of liquid soap dissolved in 2000 cc. of water and administered at 104°F). A moderate degree of generalized injection, with the appearance of a diffuse glairy surface, is apparent. In some subjects greater amounts of mucus, even amounting to distinct blobs, appeared. It was interesting to note that the subject just mentioned reacted less strikingly to all forms of stimulation than did some of the others.

Hypertonic salt solution a 17 per cent solution of sodium chloride, when applied locally for two periods of thirty seconds each, invariably produced a local, circumscribed erythematous area which soon became covered with a glairy, glistening mucoid secretion. The markings of the veins disappeared in the brilliantly injected center of the lesion. This response is illustrated in Plate 1*c*.

In addition to the local mucosal reaction, hypertonic salt solution appeared to have the property of setting up definite waves of contraction of the musculature of the upper rectum when locally applied at this site. This phenomenon was observed in 8 of 10 subjects. Partial spasm of the rectosigmoid sphincter was noticed in 7 of the 10 individuals. The rate of the peristaltic contraction in the rectal ampulla is recorded graphically in Figure 1. The peristaltic waves so set up are of low amplitude, but for each subject a strikingly characteristic rate is present, a fact which in a number of cases has been confirmed by subsequent stimulation with other substances.

When hypertonic salt solution was applied in the sigmoid above the upper valve, 1 subject, whose peristaltic rate had been 16 per minute on rectal stimulation, showed a rate of only 6 per minute. One other subject showed a few questionable contractions, which were, however, inadequate

for counting. In the other cases there was no peristaltic response in this area. The local mucosal reaction was in every respect identical with that produced within the rectum. (See Plate 1*c*).

In 3 cases oil of turpentine was applied locally. A small area of injection was consistently produced, with disappearance of the venular markings. Although this area was somewhat shiny, the exudative, glairy surface seen after the application of salt was absent. In 2 of the 3 subjects stimulation within the rectum produced peristaltic contractions at about the same rate as those produced by salt solution (Fig. 1). In the third case there was no

Figure 1. Differential Irritability of Rectum and Rectosigmoid. Each set of parallel columns represents one subject. The ordinate represents the number of contractions per minute produced by local stimulation with an irritant which was applied in each instance for two periods of thirty seconds each. Note that in only one instance was any rhythmic activity set up by stimulation above the rectosigmoid valve. Stimulation below this point quite frequently produced reflex contractions.

peristalsis. In none of the 3 was there any spasm of the rectosigmoid sphincter. When turpentine was applied in the rectosigmoid the usual local mucosal response occurred, but there was no peristaltic activity whatever, and no spasm.

The effect of *epinephrine hydrochloride* in 0.1 per cent solution was investigated in 2 cases. In each it was applied locally twice, for thirty seconds each time. In both instances a local blanched area with a slightly glossy surface was produced. In one of these the application was made in the ampulla of the rectum and was followed by the onset of active peristalsis. In the other it was applied in the rectosigmoid, from which point an acute sharp pain was referred to the umbilicus, but no peristaltic activity ensued.

*Benzedrine sulfate** was applied locally in only 1 control subject, and in a 0.5 per cent concentration was utterly inert. It was also employed in 2 patients with established "mucous colitis," but was

without effect in relieving spasm or in altering the mucosal picture. Its effect upon the x-ray picture when given in large doses by mouth has been demonstrated by Myerson and Ritvo¹⁰. In our experience, doses of 20 or 30 mg given orally failed to produce immediate relaxation in several patients with "mucous colitis." Prolonged oral administration, however, yielded symptomatic relief.

Atropine sulfate, in solutions varying in strength from 0.1 to 0.6 per cent, was applied locally in 12 cases in which spasm was present. Occasionally a moderate degree of spasm of the rectosigmoid valve was found at the time of the initial observation, it was probably due to emotional factors, which are discussed below. Under these circumstances atropine was applied in 4 cases. A 0.1 per cent solution relaxed the sphincter in one case and failed to do so in a second, a 0.3 per cent solution produced relaxation in a third, while in a fourth, a 0.5 per cent solution not only failed to relax the sphincter but in addition produced symptoms of toxicity. In 3 cases, atropine sulfate solutions of strengths varying between 0.1 and 0.6 per cent were at least partially effective in relieving spasm produced by cholinergic drugs. In 5 patients with "mucous colitis," atropine solutions, in concentrations from 0.2 to 0.5 per cent, were successful in 1 case, partially successful in 2, and utterly inert in the remaining 2.

Acetyl-β-methylcholine chloride^{17*} in 1 per cent solution, when applied locally in the rectal ampulla, was found in 10 cases to produce a small circumscribed area of injection in all respects similar to that produced by hypertonic saline solution, it had, however, no more dramatic or sustained effect than the latter. In a few cases there occurred peristaltic activity, which was entirely comparable with that produced by saline solution.

Pilocarpine hydrochloride in 1 per cent solution was found to produce very dramatic effects when locally administered in 10 normal subjects. These changes consisted in an immediate bluish-red, almost magenta, injection with a brilliantly glairy mucoid surface. Simultaneously with these changes there appeared a fine wrinkling of the surface of the mucosa, followed by gradual invagination into overlapping folds of tissue. Within five minutes these folds met in the center of the lumen, completely obstructing it with "a squirming spasm." These changes are illustrated in Plate 1d. A graphic representation of the changes following the administration of pilocarpine as well as of other drugs is given in Figure 2, this shows the consistency of the findings throughout the entire group of subjects.

Physostigmine sulfate in 0.5 to 1.0 per cent solu-

tion was found to produce equally dramatic although less rapid changes, which were consistently demonstrated in the 8 subjects studied. Subsequent to its application (two times for thirty seconds each) the first change occurred in about three to five minutes, when there was a cloudy, diffuse mucosal swelling (Plate 1e). The surface was glossy, but injection was usually less prominent than pallor. In some instances there appeared central pallor, with injection about the edges or in traumatized areas. A coarse wrinkling of the surface then developed, and heavy invaginated folds gradually formed. In ten to fifteen minutes they met in the midline and produced the picture of complete spasms illustrated in Plate 1f.

Acetyl-β-methylcholine chloride was administered by mouth to 10 subjects. In 3 of them (M.O., P.A.T., W.O.R.) 200 mg was given two hours before the sigmoidoscopic examination. In the other 7 subjects repeated large doses (1000 mg per day) were given over a longer period of time, and examinations were performed on the mornings of the second and fifth days. In some cases, still larger doses, up to 3000 mg daily, were subsequently given, but the changes produced were not substantially greater.

In all cases definite mucosal changes took place, these are graphically represented in Figure 2. The changes illustrated in Plate 1g are those present in one of the more stable subjects. In general, the changes produced by orally administered acetyl-β-methylcholine chloride consisted in a bluish-red injection most marked between the middle and upper rectal valves. In this area the veins were usually obscured, although they tended to be prominent below the middle and above the upper valves. The surface of the mucosa was finely wrinkled, with the ridges pointing in all directions. This surface was shiny but not glairy. In general, the caliber of the rectum and rectosigmoid was somewhat reduced, although real occluding spasm was present in only 2 cases.

Subjective symptoms were produced in all the patients who took the drug over a period of days, and in 1 who had but a single dose. Five of the men suffered from a tendency toward diarrhea, 1 having associated severe abdominal cramps and 2 uncomfortable low-back pain. Three of the remaining subjects had definite constipation. The other 2, who had only single doses, were symptom free.

Carbaminoylcholine chloride^{18†} in doses of 0.012 and 0.024 mg daily, was administered by mouth to 2 subjects. The changes produced were essentially the same as those produced by acetyl-β-methylcholine chloride, and consisted of diffuse injection principally between the middle and upper valves,

*Furnished in the form of Mecholyl through the kindness of Merck and Company, Rahway, New Jersey.

†Furnished in the form of Doryl through the kindness of Dr. Isaac Starr, Jr., Philadelphia, and Merck and Co., Rahway, New Jersey.

prominence of veins in the non-injected areas, a finely wrinkled, glossy surface, and reduction in caliber. The subject who received 0024 mg daily complained of diarrhea similar to that from which he had suffered after taking acetyl- β -methylcholine chloride. The other subject developed no symp-

was made as to the presence or absence of a simultaneous facial blush.

The degree of difference between the initial observation and characteristic subsequent observations, at the moment of introduction of the sigmoidoscope, is graphically recorded in Figure 2.

DISCUSSION

The changes produced in the mucosa of the rectosigmoid by the administration of cholinergic drugs are akin to those seen in that vague group of disorders best recognized under the term "mucous colitis." Recognized from antiquity, this group of patients was particularly studied by Da Costa¹⁰ in this country and by the dynamically minded European clinicians of the late nineteenth and early twentieth centuries, Nothnagel,²⁰ Von Noorden,²¹ Ewald²² and others.

The clinical picture of the "mucous colitis" syndrome consists of abdominal pain, usually felt below the umbilicus, and usually related to the ingestion of food or to defecation. Constipated or loose stools of small caliber are generally present and in many cases are streaked with mucus. In some cases there is a generalized abdominal tenderness, most acute in the left lower quadrant, where the sigmoid is usually palpable as a tender, firm mass. In others there are circumscribed attacks of severe colic followed by the passage of long strings of mucus, alternating with periods of comparative comfort. The course of the disease is protracted, with frequent exacerbations and remissions. It usually occurs in tense, nervous persons.

Singer's¹⁰ early description of the rectal and sigmoidoscopic findings in this condition was somewhat amplified by Friedenwald, Feldman, and Rosenthal,¹¹ who described three stages in its development.

- 1 Engorgement of vessels, dilation of capillaries, mucous membrane covered with glairy mucus giving a shad-roe appearance.

- 2 Vessels no longer standing out, glairiness gone, but distinct patches of tenuous mucus present, surface injected.

- 3 Mucous membrane thinned out, pale, covered with dry mucus, pinhead ulcerations seen when mucus is removed.

In any stage spasm may be present to such a degree as to render the passage of the sigmoidoscope painful. The sigmoidoscopic examination of a patient with mucous colitis is reproduced in Plate 1*h*. The disappearance of vascular prominence, the generalized injection, the absence of glairiness and the presence of patches of tenuous mucus are characteristic of the second stage described by Friedenwald, Feldman and Rosenthal.

Among the early workers to describe the x-ray

Figure 2 Schematic Description of Mucosal Appearance. Note consistent changes produced by pilocarpine hydrochloride and physostigmine sulfate locally and by acetyl β methylcholine chloride and carbanisoylcholine chloride orally, also the lesser changes produced by soap-suds enemas. Some of the subjects showed changes at the first examination which tended to disappear subsequently. These were attributed to unwarranted apprehension.

toms at all. A graphic representation of the observed mucosal changes is given in Figure 2.

CHANGES NOTED DURING EMOTIONAL STRESS

In the course of these observations it became apparent that a number of the subjects approached their initial examination with a degree of apprehension subsequently proved unwarranted. In tabulating the data it was also noted that in 6 of the 10 subjects the original description of the initial examination revealed changes which were not present to the same degree at the time of introducing the sigmoidoscope on subsequent occasions. In one instance the hospital artist, a woman, noticed a distinct injection of the mucosa when she first examined the subject, in the course of a few minutes it had largely disappeared. No observation

changes in "mucous colitis" were Singer and Holzknecht,²³ who called attention to the characteristically reduced caliber of the lower colon. Schwartz²⁴ again called attention to the reduced caliber of the descending colon and sigmoid, and noticed very sudden occurrence and relaxation of spasm. Discovery of the "string sign," a fine, tenuous shadow supposedly produced by a mixture of barium and mucus in the spastic descending colon, is generally attributed to Crane,²⁵ while Kantor²⁶ made observations on the rapid rate of movement of colonic contents in this condition. Knothe⁹ applied the barium relief technic to the problem and described a finely wrinkled sigmoid. Von Bergmann and Kutsch²⁷ were successful in demonstrating changes in the caliber of the entire colon in normal individuals following the administration of atropine and pilocarpine—relaxation after the former, marked degrees of spasm after the latter. This observation was a definite contribution to the physiology of the colon, particularly as it is altered in mucous colitis. However, the x-ray findings in the disease have been shown to be extremely inconstant. Spasm, the most constant characteristic reported by Friedenwald, Feldman and Rosenthal,¹¹ was present in only 51 per cent of the cases, while they reported sigmoidoscopic changes in 89 per cent of 438 cases so examined. The sigmoidoscopic examination in their experience would seem to be of greater significance both theoretically and practically than examination by x-ray. Similarly, the experimental production of mucosal changes by the administration of cholinergic drugs as indicated in the above data seems of greater significance than the production of x-ray changes in tending to confirm the general belief that neurogenic, and probably psychogenic, factors play a significant role in the development of this symptom complex.

The development of constipation or of diarrhea in the subjects who were given large oral doses of acetyl- β -methylcholine chloride and carbaminoylcholine chloride, is of further interest, since these symptoms are commonly experienced in "mucous colitis." In fact, the changes produced by cholinergic drugs have been so strikingly like those seen in "mucous colitis" that we have come to believe the converse to be true, namely, that mucous colitis is the result of some form of overstimulation mediated by the parasympathetic fibers innervating the colon.

The incidental data collected on the difference in irritability of the rectal wall from that of the lower sigmoid (Fig 1) are suggestive confirmation of the theory of defecation advanced through the work of Bayliss and Starling,¹⁻³ Cannon¹³ and

Hertz,¹⁴ that is, that the passage of fecal matter from the relatively insensitive sigmoid into the more irritable ampulla is the stimulus which normally activates the defecation reflex. This increased reflex irritability is apparently unrelated to subjective pain or temperature sensation, which Hertz has shown to be absent in the normal rectum. It is probable, therefore, that in the type of constipation characterized by rectal retention,—the "dyschesia" of Hertz,—the underlying cause is, as he originally hypothesized, a diminution of the sensitivity of the rectal reflex. That this is probable is also attested by the work of Hines, Lueth and Ivy,¹⁵ who found an absence of deep rectal contractions, as measured by the manometric method, in a group of constipated hospital patients. Unfortunately, they made no effort to classify the type of constipation.

Work is now in progress to determine whether the difference in irritability between the lower sigmoid and the rectum is consistently present in a large series of cases.

SUMMARY

1 The rectal and rectosigmoid mucosa in a group of healthy, young adult males was studied with the aid of a sigmoidoscope.

2 Following the local application of certain irritants, it was noted that the rectum tended to show more reflex activity than the lower sigmoid.

3 After the local application of pilocarpine hydrochloride or physostigmine sulfate, or after the oral administration of acetyl- β -methylcholine chloride or carbaminoylcholine chloride, definite mucosal changes, simulating the sigmoidoscopic picture of "mucous colitis," were produced. All these drugs stimulate or mimic the action of the parasympathetic nervous system.

4 The response to other drugs affecting the autonomic nervous system was investigated.

THE TREATMENT OF HAY FEVER BY INJECTIONS OF POLLEN EXTRACT EMULSIFIED IN LANOLIN AND OLIVE OIL

A Preliminary Report

HYMAN L NATERMAN, M.D.*

BOSTON

THE injection of pollen extracts into patients with hay fever is one of the most valuable measures available for the treatment of this condition. Despite many improvements in technic and methods since the introduction of this procedure there are objections to treatment with the solutions of extracts now employed. The large number of injections usually required makes the procedure costly and often inconvenient for the patient. Furthermore, general reactions which may follow an injection are disconcerting and may at times have serious consequences. If the absorption of pollen extract after injection could be made more gradual it seemed likely that many advantages would result.

Attempts have been made to diminish the rate of absorption and to prolong the effects of therapeutic agents given by injection, but with little practical success.¹ Straus,² in 1933, reported good results with the use of emulsions of diphtheria toxoid in lanolin, for immunization against diphtheria.

Studies at the Beth Israel Hospital during the last four years indicate that following the injection of certain dyes and drugs emulsified in anhydrous lanolin and olive oil, the rate of absorption of the substances is diminished and the effects of the drugs are prolonged. Similar emulsions of pollen

extracts have been used in treating patients with hay fever. These studies are reported below.

RATE OF ABSORPTION AND THERAPEUTIC EFFECT

The rates of absorption of phenolsulfonphthalein from water solution and from emulsion in lanolin and oil were compared by determining the rate of excretion of the dye in the urine after injection of each preparation. A stock solution of phenolsulfonphthalein in distilled water containing approximately 100 mg per cubic centimeter was prepared, using enough sodium hydroxide to effect solution. One part of the stock dye solution was emulsified in 5 parts of lanolin by trituration in a mortar and 4 parts of olive oil were added, resulting in an emulsion containing approximately 10 mg of phenolsulfonphthalein per cubic centimeter. A similar 1:10 dilution of the stock dye solution was made in distilled water. All ingredients were sterilized by autoclaving.

Five patients received 10 cc of each preparation of phenolsulfonphthalein intramuscularly on different days, and the hourly excretion of the dye was measured by the standards used in the renal function test. The average excretion is shown in Figure 1. After injection of the watery solution, 38 per cent was excreted in the first hour. In 4 of the 5 cases, excretion was virtually complete at the end of three hours. After the injection of the emulsion, less than 10 per cent of the dye was excreted in the first hour, and the hourly excretion

*From the Anaphylact. Clinic and the Medical Research Department, Beth Israel Hospital, Boston, and the Department of Medicine, Harvard Medical School.

Teaching fellow in medicine, Harvard Medical School, assistant physician, Beth Israel Hospital, Boston.

during the next seven hours ranged between 10 and 5 per cent. Appreciable amounts of the dye still appeared in the urine eight hours after injection of the emulsion.

That an active drug emulsified in lanolin and oil exerts a more prolonged effect than does a watery solution can be shown by measuring the antidiuretic effect of pitressin when administered in each medium. The preparations compared consisted of pitressin* in water (20 units per cc) and pitressin emulsified in lanolin and oil (20 units per cc), made by emulsifying 1 part of pitressin solution (400 units per cc) in 5 parts of lanolin and 14 parts of olive oil.

Figure 1. Average dye excretion per hour in 5 patients injected intramuscularly on different days with the same amount of phenolsulphonphthalein in water solution and in emulsion in lanolin and oil.

The daily urinary output of a twenty-nine-year-old man with idiopathic diabetes insipidus was measured under four standard conditions: (1) no treatment, (2) surgical pituitrin, 0.5 cc (10 units), given intramuscularly twice daily, (3) pitressin in water solution, 0.5 cc (10 units), given intramuscularly twice daily, (4) pitressin emulsified in lanolin and oil, 0.2 cc (4 units), given intramuscularly once daily. The effect on the urinary output is shown in Figure 2. With no treatment, the daily urinary output varied between 250 and 320 oz. The antidiuretic effect of each injection of surgical pituitrin was so temporary that the daily output was the same as during the control period. The watery solution of pitressin also caused no significant diminution in the daily urinary output. However, when pitressin emulsified in lanolin and oil was given in much smaller doses, the urinary excretion was decreased to about 60 oz, and the antidiuretic effect of each injection was maintained for at least twenty-four hours. Pitressin emulsions in 2 other

cases of diabetes insipidus showed similar prolonged effects.

METHODS

Method of Preparation. A 1:10 ragweed extract was prepared by extracting ragweed pollen with Coca's buffered solution,³ using 1 gm of pollen to 10 cc of solution. On February 27, 1937, a 1:100 pollen-extract emulsion was made by stirring 2 parts of extract into 5 parts of anhydrous lanolin until the entire solution was taken up by the lanolin, 13 parts of olive oil were then mixed in. The mixture was passed through a homogenizer* to make sure of complete emulsification, this step is not essential, however. A 1:500 emulsion was made by diluting the 1:100 emulsion with olive oil. This 1:500 emulsion was used until April 29, 1937, when a more viscous preparation of 1:500 was made by diluting the 1:100 emulsion with 25 per cent lanolin in olive oil. On July 29, 1937, a fresh 1:50 emulsion was made, using 20 cc. of an equal mixture of 1:10 pollen extract and glycerin emulsified in 30 cc. of an equal mixture of lanolin and olive oil. All ingredients and utensils were sterile.

Figure 2. Daily urine excretion in ounces in a case of diabetes insipidus treated with injections of surgical pituitrin, 0.5 cc twice a day, pitressin in water, 0.5 cc twice a day and pitressin emulsified in lanolin and oil 0.5 to 0.2 cc once a day.

Selection of Cases for Treatment. Two criteria were considered in the selection of cases for treatment, (1) severity of symptoms, (2) degree of sensitivity as shown by the scratch skin test, and the local reactions after the subcutaneous injection of a small dose of ragweed extract. Only patients with moderate to severe symptoms of hay fever were accepted, 3 had asthma in addition to hay fever.

Skin tests in each case were done before treatment by the scratch test method on the forearm,

*Pitressin powder supplied by Parke Davis and Company, Detroit, Michigan.

*Portable hand homogenizer made by Club Aluminum Products Co., Chicago, Illinois.

using dilutions of ragweed extract in Coca's solution in 1 50, 1 500 and 1 5000 dilutions. The maximum reaction to each test, usually after fifteen minutes, was drawn on the record, the description including wheal and erythema, in most instances the test reactions were measured. All the cases had moderate to marked positive reactions to the 1 50 and 1 500 dilutions, and 8 had positive reactions even to the 1 5000 dilution.

Twelve patients had had from one to three subcutaneous injections of ragweed extract, 1 5000 in Coca's solution, 10 had received 0.10 cc., 1 (Case 10) had received 0.05 cc., and 1 (Case 1) had received 0.15 cc. The local reactions which had

All injections were given subcutaneously in the upper arm with a 26- or 27-gauge needle after the syringe was loaded by using an 18-gauge needle. Because local indurations may develop if injections of lanolin and oil are repeated too frequently in a small area,⁴ the sites of injection were varied. No local indurations or infections appeared after any injection given to this group of patients.

Cases 12 and 17 began treatment late and received six and five injections, respectively, before the beginning of the season, the maximum doses being 0.50 cc of 1:500 and 0.075 cc of 1:50 emulsion, respectively. In the remaining 15 cases, the

* Asthma in addition to hay fever

developed were large in 6 patients (Cases 2, 5, 6, 10, 16 and 17), moderate in 2 (Cases 1 and 15), and small in 4 (Cases 3, 4, 11 and 13). One patient (Case 7) had had no reaction with 0.10 cc. of 1:1000 ragweed extract.

Method of Treatment The initial dose was 0.10 cc of 1:500 emulsion with the exception of 2 cases which began with 0.15 cc. (Case 1) and 0.05 cc. (Case 14). The subsequent doses were increased at weekly intervals according to the local reactions until the maximum dose was reached. If this amount was reached long before mid-August, as in cases started on treatment early in the year, the maximum dose was repeated at intervals of two to four weeks. Four patients (Cases 12, 15, 16 and 17) who began treatment in July were given two injections a week until the beginning of the ragweed season, about August 13. Up to July 29, the maximum dose was 0.50 cc. of the 1:100 preparation. This was made on February 27, and since it was five months old and had possibly deteriorated, a fresh 1:50 emulsion was made on July 29, which was used with some patients, the maximum dose being 0.50 cc.

maximum dose varied between 0.20 and 0.50 cc of 1:50 emulsion or its equivalent (Table 1). The number of injections given to attain this maximum varied between seven and twelve, with an average of nine. The maximum dose was repeated at increased intervals with many of the patients until the beginning of the ragweed season. In some cases, doses following the maximum were reduced because of a large local reaction, or because of the approach of the season.

The season is considered to extend to the end of September. The doses given during the season were less than the maximum dose reached before it began.

RESULTS

Local and General Reactions To determine whether pollen-extract emulsion was more slowly absorbed than the solution in water, 10 patients were injected at the same time with a 1:5000 solution into one arm and a 1:500 emulsion into the other. The amount usually injected was 0.10 cc. The size of the reaction produced by each injection was observed up to one hour. Invariably, the

emulsion produced a smaller immediate local reaction than the solution, even though it contained ten times the amount of pollen extract. After several hours, however, the local reaction from the emulsion approached that from the solution, and often became larger and lasted longer. This indicates that absorption of the pollen extract from the emulsion was delayed.

Three patients had general reactions. In Case 14 the patient received 0.10 cc of 1:50 emulsion on August 2 and 0.20 cc on August 9. Five minutes after the last injection he developed a large local reaction, accompanied by wheezing. He responded quickly to 0.50 cc of 1:1000 adrenalin, and no tourniquet was necessary. In Case 15 the patient received 0.35 cc of 1:100 emulsion on July 23. A week later he was given 0.25 cc of 1:50 emulsion, and about five minutes later developed wheezing which did not require treatment. The following day the local reaction was "larger than usual." In Case 17 the patient received 0.50 cc of 1:500 emulsion on August 6. Three days later she was given 0.075 cc of 1:50 emulsion. About thirty minutes after injection, while on her way home, she developed a large local reaction and a "wheezy feeling" which persisted until the next day. She did not call a physician.

All three of these general reactions occurred after the patients had been given a freshly made 1:50 preparation, the preceding injections having consisted of material five months old which had probably deteriorated to some degree. The reactions were mild, and did not resemble the acute, dramatic, general reactions occasionally seen with the usual ragweed solutions.

Effect on Skin Reactions. Each case was skin-tested before treatment. At intervals thereafter the scratch tests were repeated and changes were noted. In every instance there was a striking progressive diminution in the size of the reaction. Before treatment, every patient showed moderate to marked reactions to the 1:50 and 1:500 dilutions, and 8 showed slight to moderate reactions to the 1:5000 dilution. After treatment, no patient reacted to the 1:5000 dilution, 5 showed questionable to slight reactions to the 1:500 dilution and 12 showed negative ones, 13 showed slight to moderate reactions to the 1:50 dilution and 4 showed virtually negative ones. For example, the patient in Case 10, who gave the most pronounced reaction to the skin test before treatment, showed the following wheals on repeated testing:

		1:50 DIL.	1:500 DIL.	1:5000 DIL.
		mm	mm	
Before treatment	April 30	55 x 38	38 x 14	Small
	August 16	8 x 8	None	None
After treatment	October 18	6 x 6	None	None

The patient in Case 17, who had the smallest number of injections, showed the following wheals:

		1:50 DIL.	1:500 DIL.	1:5000 DIL.
		mm	mm	
Before treatment	July 26	18 x 18	5 x 5	None
After treatment	August 16	10 x 10	None	None

To determine whether the tolerance to ragweed extract was increased by treatment with emulsion, 8 patients after reaching a dose of 0.40 or 0.50 cc of 1:100 emulsion were injected with 0.10 cc of 1:100 ragweed solution. The reactions produced ranged from negative to very slight.

Clinical Results. The evaluation of results in the treatment of hay fever is difficult. After treatment, one patient may have more symptoms than another, yet show more improvement. Also, some patients complain more than do others whose symptoms are more severe. With these considerations in mind, the patients have been grouped according to clinical results in three arbitrary divisions.

Excellent Results. This group comprises 5 patients (Cases 2, 6, 10, 11 and 16) who had no days of discomfort during the entire season. On close questioning, they admitted that on arising they occasionally had some stuffiness in the nose and slight sneezing which lasted only a short time, with no discomfort during the remainder of the day or night. No symptomatic treatment was required in this group. Four patients had no injections after the season started and 1 (Case 10) had one.

Good Results. This group includes 10 patients (Cases 1, 3, 4, 5, 7, 8, 9, 13, 14 and 15) who had mild symptoms of hay fever during the day on four or five occasions during the season, but did not require active symptomatic treatment. In comparison with years in which they had had no treatment, the degree of relief was marked. No patient was incapacitated at any time. The 3 patients who had asthma in addition to hay fever had much less discomfort than in other years, and the wheezing was readily controlled by ephedrine sulfate, 3/8 gr. Only 3 of the 10 patients received more than one injection during the season.

Fair Results. Two patients (Cases 12 and 17) who reported for treatment late in July, and received only six and five injections, respectively, before the onset of the season, had more symptoms than the other patients in this series. They were, however, definitely better than in previous years in which they had received no treatment.

DISCUSSION

Microscopic examination of an emulsion of water in lanolin and oil shows the watery phase as minute droplets surrounded by lanolin and oil. When such an emulsion is injected, each droplet must be

liberated from its envelope before it can come in contact with the tissues and be absorbed. The same amount of water if not emulsified can be absorbed much more quickly, as shown by a comparison of phenolsulfonphthalein excretion from solution and from emulsion (Fig 1). In the same way, an active drug when emulsified has a prolonged absorption and prolonged action. As indicated in Figure 2, 4 units of emulsified pitressin once a day had a prolonged antidiuretic effect sufficient to control a case of diabetes insipidus for at least twenty-four hours, whereas 10 units in solution given twice a day had so temporary an effect that the twenty-four-hour urinary excretion was the same as when no treatment was given. This technique has been applied to other active drugs.⁴ Several patients with bronchial asthma have had longer periods of relief between attacks when emulsified adrenalin was used than when adrenalin in 1:1000 solution was given. In fasting rabbits, emulsified insulin produced hypoglycemia lasting eight hours or more as compared with three hours when the same amount of insulin was given in solution.

Delay in the absorption of emulsified pollen extract is indicated by the fact that milder immediate local reactions were produced by injections of emulsified extract than by those of watery solutions, even when the amount of extract in the emulsion was ten to twenty times as great as that in the solution. The value of this method of delayed absorption in the treatment of hay fever may be determined by comparing the results in this series with those obtained by treatment with extracts usually used. When pollen extract in water solution is injected into a sensitive patient, the entire amount comes into immediate contact with the antibodies in the tissues and the maximum reaction starts immediately. With emulsion, however, only part of the extract comes into immediate contact with the antibodies, the remainder being slowly released. Because of this, a larger amount of pollen extract may be given in emulsion. The patients in this series were all started on treatment with a 1:500 dilution, whereas the usual initial dose of pollen extract in patients with the degree of sensitivity manifest in this group is a 1:5000 or weaker dilution.^{2, 5, 6} Since larger doses may be given, a specified maximum dose can be reached with fewer injections. The maximum dose aimed at is usually 0.50 cc of a 1:100 or 1:50 dilution of extract, requiring from fifteen to twenty-five injections of the extract in solution. This dose was reached in this series by from seven to twelve injections of emulsified extract with an average of nine, approximately half the number usually required. Furthermore, if the data in 4 cases treated in 1936 with ragweed solution and in 1937 with

emulsion (Table 2) are compared, it is evident that fewer injections of emulsion resulted in a

Table 2. *Comparison of Treatment and of Results in 4 Cases of Ragweed Hay Fever Treated in 1936 with Ragweed Extract in Solution and in 1937 with Ragweed Extract in Emulsion*

CASE No	TREATMENT	MAXIMUM DOSE		NUMBER OF INJECTIONS	CLINICAL RESULTS
		dil	cc		
5	Sol	1:500	0.40	11	Poor

	Emul	1:50	0.55	9	Excellent
13	Sol	1:100	0.05	9	—
	Emul	1:50	0.45	10	Good

This patient received no injections between July 24 and September 4 1936 so that the results obtained in that year are not considered comparable.

higher maximum dose. The decrease in the number of injections reduces the expense and inconvenience to the patient, so that more patients with hay fever will find it possible to take treatment. Since the time necessary for preseasonal treatment is shortened, patients starting treatment late have more chance of getting good results. In cases reporting after the onset of the season, it is also possible that treatment with emulsions may be more effective than treatment with watery solutions. In using emulsions of lanolin and oil, care must be exercised to avoid injecting too frequently into the same area. Several patients who injected themselves at home with pitressin or adrenalin emulsions developed temporary local indurations which were apparently due to neglect of this precaution. A few instances of minor local infection also occurred after self-administered emulsions. No injection of emulsion given by us has caused any local complications, and none were encountered in this series. The injections are painless except for the needle puncture.

The effect on the sensitivity as indicated by skin tests is of interest. The ability of treatment with pollen extracts to affect the skin sensitivity has been open to question, a definite decrease in the size of skin tests as determined by the scratch method, however, has been demonstrated in some cases following treatment.⁷ All the patients in this series showed marked reduction in the size of the skin tests. It seems likely that the slow absorption from emulsion permits the extract to act over a longer period of time, and thereby to serve as a better desensitizing agent, than is the case with the extract in solution. It is possible, therefore, that this method may result in a higher percentage of cures than that now obtained. Also, the greater desensitization may make it possible to increase the intervals between injections in the perennial form of treatment.

The danger of general reactions is everpresent, and may have serious consequences.⁸ To avoid these severe immediate anaphylactic reactions, the application of a tourniquet proximal to the site of the injection and the addition of adrenalin to the pollen extract have been advised, in order to delay the absorption of the pollen.⁹ These precautions are not sufficiently observed, unfortunately, because of their inconvenience. Although adrenalin may slow the absorption of pollen extract from the site of injection, the entire amount of pollen does come in immediate contact with the tissues, and if the reaction is violent enough, a general reaction may occur. With the use of emulsions, where only a part of the pollen extract reaches the tissues at any one time, it is reasonable to suppose that the tendency to severe general reactions will be greatly reduced, especially if the methods now advised are used.

The clinical results obtained in these cases were very satisfactory. There were no failures in treatment, even the 2 patients whose treatments started late and who received only five or six injections had at least fair results. Of the remaining cases, 5 had excellent results and 10 good results. There is reason to believe an even higher percentage of excellent results may be obtained by larger dosage and more treatment during the pollen season. The results compare favorably with those obtained from the usual treatment with solutions,^{3, 6, 6} and in the cases of this series which were treated in 1936 with solutions, the results with emulsions were definitely better.

The advantages of pollen-extract emulsions as compared with the solutions now used seem apparent, and the findings in this series are significant. The results warrant a more general application of this method.

SUMMARY AND CONCLUSIONS

A method is described for emulsifying water solutions of drugs in anhydrous lanolin and olive oil. Evidence is presented that such drugs when injected are more slowly absorbed, have a more prolonged action, and are therefore more effective than when administered in water solution without emulsification. Emulsions of ragweed pollen extract were utilized in the preseasonal treatment of 17 patients with moderate to severe symptoms of hay fever and moderate to marked sensitivity to ragweed pollen.

In comparison with the treatment of such patients by pollen extracts in solution as now used, certain advantages of the emulsions are apparent.

1 Pollen extracts in emulsion are more slowly absorbed. Ten times as much pollen extract in emulsion produced less immediate local reaction than the solution.

2 Larger doses may be given. The patients in this series received an initial dose approximately ten times as great as usual.

3 The number of injections necessary to reach the usual maximum dose of 0.50 cc. of a 1:100 or 1:50 dilution is reduced. This dose was reached in an average of nine injections, about half the number usually required with the solutions now in general use.

4 Sensitivity as indicated by skin tests is markedly reduced.

5 The tendency to severe general reactions is decreased because of the slow absorption of the extract.

6 The clinical results are as good or better with the extract in emulsion than with the extract in solution. There were no failures. Two patients who started treatment late and failed to reach the usual maximum dose had fair results. Of the remainder, 10 had good results, and 5 had excellent results.

THE ADRENOGENITAL SYNDROME AND ADRENOCORTICAL TUMORS

GEORGE F CAHILL, M.D.*

NEW YORK CITY

DYSFUNCTIONS of endocrine glands produce, at times, changes in metabolism and in physical characteristics. Certain such changes belonging in the sexual sphere have been described as the adrenogenital syndrome, and have been shown to be caused in some cases by a tumor in the adrenal cortex. On the other hand, tumors of the adrenal cortex have occurred without producing any recognized endocrine change. Again somewhat similar syndromes have developed with tumors of other glands,—the pituitary, pineal, thymus, testis or ovary,—or without demonstrable glandular tumors. So that the only information as yet available relates to part of the mechanics involved in the dysfunction.

There have been under observation since 1927 at the Squier Clinic 35 cases of adrenocortical disturbances, 8 male and 27 female. Some showed syndromes due to adrenal tumors, but in others no such tumor could be proved. Certain other cases had adrenal tumors but no endocrine dysfunction. A discussion of this complex problem as seen in this series may be of interest.

SYMPTOMS

Corticoadrenal tumors may exist with or without the adrenogenital syndrome. When the syndrome is present the endocrine changes appear to follow three more or less separate paths. The most frequent change is the development of the secondary sexual characteristics of adult masculinity, and is best termed androtropic; secondly, evidences of maturity may occur in the young and those of an even more advanced age in the mature; thirdly, there may be changes in metabolism affecting mostly the plasma, the fat distribution, the skin and the psychologic balance. The symptoms of this syndrome vary according to the sex and age of the patient and the degree of malignancy of the tumor. Since similar syndromes occur without demonstrable tumor, a review of the symptoms, with a discussion of their divergence in tumor and non-tumor cases, may give the clearest picture that can be shown at present in these unusual clinical states.

When the tumor occurs in the male before

puberty, precocious sex development is the most frequent symptom. Associated with this phenomenon there is an increase in muscular development which produces in some individuals the so-called Herculean type. This condition, according to Harris and Plewes,¹ characterizes over 60 per cent of the collected cases. There is often a proportionate increase in athletic ability. In addition, a premature growth of hair occurs on the genitals, face, body and extremities, and the hair is frequently coarse and dark. The genitals enlarge and become adult in type. Coinciding with this precocious development, substances with male hormone properties appear in the urine, although according to Womack and Koch² most boys under ten do not excrete demonstrable amounts of male hormone. Rapid growth takes place but is followed by cartilage loss with cessation of growth, so that the subject may actually become much shorter than children of the same age. The dentition is advanced. A certain number of subjects develop obesity, most marked in the face and trunk, and redness of the face. Skin changes such as acne occur as at puberty. Precocious tastes and appetites, including sexual desire, may develop. Frequently, children show mental development beyond the age index.

Similar endocrine changes, described as macrogenitosomia praecox, have occurred with tumors of the pineal gland. An interesting group of cases with similar sexual symptoms without evidence of tumor, occurring in one family, was classified by Rush and his co-workers³ as primary, primary constitutional, or congenital pubertas praecox. He believed that such a condition was determined genetically. We studied 4 male children with macrogenitosomia praecox. The first child, aged five, with premature puberty, showed no abnormal change in his pineal, pituitary, thymus, gonadal or adrenal glands by x-ray or otherwise, so that a cause for the endocrine abnormality could not be demonstrated. The second boy, aged seven, was sexually mature and had the height and weight of an eleven-year-old. There were also epiphyseal changes corresponding to those of twelve or over. There were no changes from normal in the pineal gland, pituitary, thymus and gonads. Air injection and x-ray revealed a left adrenal gland enlarged to about one third the size of the kidney, and an apparently normal one on the right. This enlarge-

*From the J. Bentley Squier Urological Clinic, Presbyterian Hospital, New York City.

Read at a meeting of the New England Branch of the American Urological Association, Boston, April 29, 1937.

Associate professor of urology, College of Physicians and Surgeons, Columbia University, New York City; associate attending urologist, J. Bentley Squier Clinic, Presbyterian Hospital, New York City.

ment is suggestive of increased adrenocortical function as the cause of sexual maturity, and implies the presence of male hormone in the urine, but whether the latter is due to hyperplasia or tumor of the gland awaits operative confirmation. The third boy, aged eleven, previously described,⁴ had marked hirsutism and hypertrophy of the genitals. The early fusion of the epiphyses, with apparent shortening of the extremities, and the continued facial and muscular growth suggested an achondrodystrophic dwarf. At the time of this boy's hospitalization we were able to show the presence of female hormones in his urine, but no facilities were then available for determining the excretion of male hormone. Air injection and x-rays of the adrenals showed a change in one which indicated hypertrophy or tumor, but the mother's failure to co-operate prevented further study. The long standing symptoms, seven or eight years in duration, with the only demonstrable anatomic glandular changes in one of the adrenals, suggest an adenoma or hyperplasia of the cortex as the causative agent. In the fourth case, also a boy of eleven, the symptoms had been present since infancy, again suggesting an achondrodystrophic dwarf with marked hirsutism and hypertrophied genitals. Although this case closely resembled the foregoing one, x-ray studies disclosed no anatomic changes in the endocrine glands. In neither of these cases was there any evidence of a hereditary or familial occurrence.

Thus of the 4 male children with adrenogenital syndrome, 2 showed anatomic adrenal changes that were suggestive of but not operatively proved to be the cause of the symptoms, while in the other 2 the syndrome had existed for relatively long periods without any causative anatomic glandular change's being demonstrable.

In the male after puberty, adrenocortical tumors have occurred without producing any endocrine changes (Hartman,⁵ Stevens,⁶ Gibson⁷ and others). Such a case was previously described¹ in which autopsy revealed a carcinoma of the right adrenal cortex with extensive metastases. A second patient, a male of thirty-six, was without symptoms except for pain in his left flank. A tumor of the left adrenal was shown by air injection and x-ray. On removal it was found to have arisen from the lower portion of the adrenal and to have grown in front of the kidney, without causing its displacement. Microscopic section showed that the tumor was derived from the adrenal cortex, but it was impossible to tell from which cell structure.

Adult males with adrenocortical tumors and evident endocrine changes have been reported. Macera⁸ described a case with adiposity, polydipsia, hypertrophy of the genitals, changes of metabolism

and increase of secondary male sexual characteristics. Long and Gray⁹ reported an adrenocortical tumor in a male acromegalic. However, such changes as occur have been mostly toward feminization, best termed gynecotropic. Among such cases Weber¹⁰ cited 2 from the literature with hypertrophy of the mammae and atrophy of the testes, both having adrenocortical tumors. More recently Holl¹¹ and Lisser¹² have each described cases of feminization of the male with such tumors. One male adult in our series had obesity, atrophy of the genitals, and a marked increase in hair. Besides the decrease in the size of the testes, the only demonstrable glandular change was an enlargement of both adrenals, shown clearly by air injection and x-ray. No operative procedures to establish the cause of the adrenal hypertrophy were permitted, and no hormonal studies were made.

In the female, when the disease occurs before birth or in early infancy, only cases of tumor with definite hormonal changes have been reported, and the symptoms have been best described as pseudo-hermaphroditic. It has been suggested that all cases of pseudo-hermaphroditism are the result of hypersecretion of the adrenal cortex. Yet the only adrenal lesions known to produce such changes are cortical tumors. Young¹³ has most interestingly described his experiences in correcting these defects, and has discussed their association with adrenal changes. The contention that such changes occurring in the secondary sex organs are due to hormonal influences, possibly apart from tumor, has received much support from the experimental work of Hain,¹⁴ who has shown that hypospadias in the female offspring of the rat may be produced by the injection of the female sex hormone (estrone) before or immediately after birth. Moreover, Greene and Ivy¹⁵ have demonstrated that male sex hormone (testosterone) when injected early in pregnancy in rats produces an arrest in the development of the vagina and a hypertrophy of the clitoris to the point of resembling a penis, or results in intersexuality (freemartin). If a tumor develops in the female before puberty and is highly malignant, death may occur before any marked changes take place. Usually the characteristic tendency toward adult masculinity is noted. This is first shown by hair growth which is masculine in its distribution. The genitals change, the clitoris increasing in size until it resembles a penis. The labia majora enlarge and become deep red. These patients, as a rule, do not menstruate even though the age of puberty has been reached. Two exceptions have been reported (Bulloch and Sequeira,¹⁶ and Cecil¹⁷). The voice is often deep and husky. Complete dentition and union of the

epiphyses occur, as in the syndrome in male children. There may be obesity of the face, neck and trunk, with an increase in the size of the mammary glands. The skin may become coarse and dry and acne may develop.

In the female after puberty and before the menopause, symptoms of the adrenogenital syndrome are more frequent—27 of our 35 cases were in this category. Of these, only 6 had proved tumors of the adrenal cortex. Adrenocortical tumors may also occur without any endocrine syndrome in the female, as shown by 1 of our patients who had a tumor on the left side, with cells mostly resembling the zona fasciculata. The changes produced tend toward the secondary sex characteristics of masculinity (androtropic). More rapid aging and metabolic changes of plasma, fat and skin which are similar to those described in younger females, take place. These androtropic changes are accompanied by a suppression of the female characteristics. The first symptoms are amenorrhea and hirsutism. At the beginning there may have been scanty menstruation, followed by its complete cessation, lasting until the tumor is removed. Headaches have frequently occurred at the time when menstruation should have taken place. Associated with the absence of menstruation there is often complete loss of sexual desire and libido. Homosexual desires have been reported by Holmes,¹⁷ with a return to normal after removal of the tumor. All our tumor cases had little or no sex thoughts, and none exhibited any homosexual trend. The menses in these cases started after the tumors were removed, sex attraction and libido returning at the same time. In 1 case metastases developed later and the menses again ceased, as did the libido.

Increase in hair or hirsutism occurred early. The pubic escutcheon became masculine in shape, and hair appeared on the face, chest, back and extremities. The hair was black and coarse, except in 1 case. A loss of head hair was also noted, 1 woman becoming bald. The growth of hair on the body may become extraordinarily profuse, especially about the genitals. On removal of the tumor the hair falls out, chiefly at the time of menstruation and frequently while bathing. In women who have shaved, the loss of hair on the face has been disappointingly slow after operation. One woman was still shaving every other day three years after removal of the tumor.

The changes in the sex organs are more marked the younger the subject. The clitoris may resemble a penis, and the labia majora become hypertrophied and reddened. In older women there has been a definite loss of ovarian tenderness on pelvic examination. At operation in all the tumor

cases, the ovaries have been extremely small and the uterus has been smaller than normal. In young subjects the breasts may resemble a boy's, but female development follows removal of the tumor. In older subjects there may be a reduction in size, with a return to normal after operation. The voice becomes deeper and more masculine the earlier the disease occurs in youth. This has been shown to be due to a marked increase in the length of the vocal cords.

With masculinization, rapid maturity, with cessation of growth and absorption of the epiphyseal cartilages, occurs in younger individuals. Older people appear to be of more advanced age than is the case. Apparently these women are not fertile during the symptomatic period of the disease, although 2 had had children before the onset of symptoms. Marked sexual changes in 1 case were not accompanied by any pronounced changes in the metabolism of plasma, fat deposits or the skin.

Metabolic changes associated with the masculinization of the individual take place more frequently, although cases have been seen in which the latter was slight and the former were marked. With these changes the skin becomes dry and coarse, and acne frequently develops. Redness and duskeness of the face and hands were marked in 2 cases. Both patients had polycythemia, one with a red-cell count of 5,700,000 and the other with one of 6,300,000, and each with a hemoglobin of 125 per cent. In 1 case the total blood volume was about 50 per cent of normal. Similar duskeness with increased red-cell counts has been described in cases of Cushing's basophilic adenoma of the pituitary, but no records of blood volume have been made. The paralleling of the symptoms and blood changes suggests that the basic mechanics of the plasma changes in these conditions may be somewhat the same, since in Cushing's syndrome additional adrenal changes have frequently been found at autopsy. Pigmentation may take place. Striae atrophicæ of the skin of the abdomen and thighs, similar to that described in Cushing's syndrome, also occur. Obesity is frequent with such changes and is restricted to the face, neck and trunk. With the more malignant tumors it is replaced by emaciation. Edema of the face, feet and hands seems also to be associated with the more rapidly growing tumors. Not infrequently shortness of breath, weakness and cardiac palpitation accompany the edema. Symptoms referable to hypertension are frequent, and hypertension of a moderate type, varying from 138 to 195 systolic, has developed in tumor cases. It was uniformly lower in the cases with marked sex changes, and higher in those with obesity and plasma changes.

The mental alterations in these patients are at times pronounced. They are emotional, and some are very depressed. All our patients were somewhat difficult to handle while in the hospital. In 1 case the emotional change was more pronounced than the physical. After the cessation of her menses the patient developed a marked inversion-depression psychosis in which she did not speak voluntarily for almost two years. She showed obesity of Cushing's type, duskiness of the hands and face, polycythemia, and slight hirsutism and amenorrhea, but there was little change in the clitoris. No male sex hormone could be demonstrated in her urine. A tumor of the left adrenal was shown by air injection and x-ray. Immediately following its removal she spoke rationally, acted in a normal manner and chatted with her husband and family, and apparently resumed her normal interest in her surroundings. Such a change upon the removal of a hormonal tumor is of extraordinary interest from the point of view of its possible mechanics. The emotional changes in other cases were just as evident but much less marked.

The basal metabolic rates showed such a variation that they could only be interpreted in relation to the general state and not in specific relation to the adrenal situation. Chemical analyses of the blood showed no particular change, except that in some cases the cholesterol content was high. There was no demonstrable change in the blood chloride, sodium or potassium. Two tumor cases showed a low sugar tolerance, and in addition metabolic and plasma changes, obesity and edema. An autopsy in 1 of these cases showed a normal pituitary gland and pancreas.

The 20 cases of women without demonstrable tumor presented a varying number of the symptoms of the adrenogenital syndrome (Broster and Vines¹⁹): hypertrichosis of the male type, menstrual dysfunction, changes in the body contour, changes in the genitalia, changes in the larynx, and changes in the psychologic outlook. Since these symptoms are also those produced by cortical tumors, a differential diagnosis in some cases is difficult without visualization of the adrenal. All in all, the changes in the cases without tumor were less pronounced and more varied than those in the tumor cases.

The changes in menstruation varied. In several the amenorrhea was primary, menstruation never having taken place. More frequently menstruation was scanty, infrequent or irregular, in contrast to the tumor cases, where complete cessation was the rule. On the other hand, some of the non-tumor cases had little change from normal. These patients did not complain of headache or

nervous, suppressed catamenial periods as did those with tumor. Not infrequently in some of the older cases there was a long history of symptoms—ten or twenty years—with little acceleration, a duration most unusual in tumor.

The hypertrichosis in the non-tumor cases was varied. In some it was of a moderate growth, but in a few it was extraordinarily profuse. The head hair, however, more uniformly kept its normal color. No tendency to baldness was seen. The hair of the body and face was coarse, but not so uniformly coarse and dark as in the tumor cases.

Changes occurred in the sex organs in 12 cases. These were an enlargement of the clitoris and an increase in the size of the labia. The breasts were undeveloped in 11 cases, in the remaining 9 they were apparently normal. At operation these cases did not show the uniformly small, contracted ovaries seen with tumors. Two had cystic ovaries, neither of which showed any masculinizing cells on section.

Obesity was present in 8 of the non-tumor cases. The most pronounced was that of a girl of 20 who weighed 365 lb. She looked at least thirty-five years old. The obesity was of a generalized type. The body contour apparently varied with the age and onset of virilism. The younger female patients resembled boys, but the older ones were feminine in appearance. Seven had male figures, there were 3 long, bony individuals who had both male and female characteristics. The voices were deeper than normal females only in those cases in which hirsutism had begun in early youth. Of the skin changes, dryness and acne were infrequent, and duskiness of the hands and face did not appear.

Emotional instability as a whole was less marked among the non-tumor cases. A few were difficult to control, because of a predominating fear of harm. Normal sex attraction with a feminine psychology was present in most. A frequent complaint was depression because of apparent lack of sex appeal.

A definite loss or lack of fecundity seems to be associated with the adrenogenital syndrome, children being unusual among those who marry. In addition, a certain hereditary or familial influence is present in some non-tumor hirsutisms. This syndrome occurred three times in sisters, and 1 of these had a cousin and two paternal aunts with the same changes. Although the comparison is only suggested, these patients often seem to resemble the animals, produced experimentally, which have been described as intersexuals or freemartins. There were no twins in any case, but there is experimental evidence showing that some hormonal influence besides that of a male twin may produce such conditions.

DIAGNOSIS

In cases of adrenal tumor without endocrine syndrome, the most frequent symptom has been pain in the side involved. The tumors as a rule have been large and often palpable in the region of the kidney, which they displace downward. This can be shown by x-ray photographs and pyelograms. As has often been stressed, the upper pole of the kidney is moved so that the hilum faces downward, a position that does not occur in ptosis or in renal ectopia. In some cases actual invasion of the kidney has given irregular compression shadows of the pyelographic media similar to those produced by renal tumors.

When the adrenogenital syndrome is present the diagnosis lies first between a possible tumor of the pineal gland, pituitary, thymus, ovary or adrenal gland. When the presence of a tumor cannot be established, increased activity of certain glands has been suggested as a cause. This activity is frequently assigned to the adrenal cortex. When a glandular tumor is present there appears to be some variation of symptoms in accordance with the gland involved. The hirsutism of pituitary dysfunction has been described as the silky, lanugo type, and the facial growth predominates on the cheeks. Hirsutism due to ovarian growth is more universal, somewhat masculine but often scanty. When the growth is due to involvement of the adrenal it is characterized by coarseness, darkness and wide distribution, being present on the lips and chin. The types of obesity in these glandular disturbances are somewhat variable. Pituitary obesity has been characterized as of the girdle type, ovarian obesity as generalized, and adrenal obesity as involving the face, neck and body, but less marked in the extremities.

To diagnose the condition of the adrenals, air injection of the perirenal fascial spaces, followed by its visualization by x-ray, has been used by us in all the established cases, and also in others where an adrenal lesion was suspected. This method,²⁰ more than any other except exploration and direct vision, has at least given us some intimation as to whether gross anatomic changes are present. A tumor was diagnosed in 9 of our cases by the use of air injection and x-ray. Bilateral adrenal hypertrophy was diagnosed in 2 others. Gross changes which could be considered as tumors were not seen in any of the other cases. In a number of cases reinjection and x-ray photography were carried out and the shadows were compared with the earlier ones, in order to see whether any change had taken place. In 6 cases the adrenal could be visualized only on one side. When the proper fascial plane was not injected in such a way as to visualize the adrenal, this side was usually reinjected with

larger amounts of air. This usually resulted in the visualization of the correct fascial planes.

The early studies on excretion of sex hormones gave a rather puzzling picture.²¹ In tumor cases, women with amenorrhea and a masculinizing syndrome showed what was considered to be normal amounts of urinary female sex hormone. Why such patients, with apparently normal amounts of hormonal excretion, did not menstruate was not clear until Gallagher²² showed that they excreted large quantities of male sex hormone, in fact larger amounts than were found in the urine of normal adult males. A reduction of the excretion after removal of the tumor was also shown. Encouraged by the possibility that such a hormonal test might be an important factor in the diagnosis, Kurczok²³ made further studies on tumor and non-tumor cases which showed that excess amounts of male sex hormone were excreted in cases of adrenogenital syndrome without tumors, being discovered either by air injection and x-ray or by operation and section. One of the largest amounts was found in a non-tumor case with hirsutism, dysmenorrhea and obesity.

It seems, so far, that excessive amounts of male sex hormone in the urine are associated with androgenic tumors. It is reduced on their removal, but the hormone may be present when no tumor can be shown, and in amounts that vary with the masculinization of the patient. With the removal of half of an adrenal in some non-tumor cases, the adrenal that was sectioned had some association with the hormonal excretion because of clinical improvement, as first shown by Broster and Vines.¹⁹ We were able to confirm this. Diminution of the amount of adrenal cortex appears to be followed by a concomitant decrease in hormone excretion.

Recent investigations by Reichstein,²⁴ by Wintersteiner and Pfiffner²⁵ and by Kendall et al.²⁶ have shown the presence of a number of sterol-like substances (steroids) in the adrenal cortex. Some of these are easily converted into substances with male hormone activity (androgenic), one androgenic steroid occurring naturally in the adrenal. From the urines of cases of adrenal tumor and of adrenogenital syndrome, a number of steroids were isolated by Callow,²⁷ by Burrows, Cook, Roe and Warren,²⁸ by Broster and Vines²⁹ and by Butler and Marrian.³⁰ Some have been identified chemically and have revealed androgenic properties, others have not yet been identified chemically nor tested physiologically. Of particular importance, however, is the compound pregnane-3, 17, 20-triol, recently isolated by Butler and Marrian³⁰ from the urine of women with adrenogenital syndromes. The excretion of this steroid seems to be associated with the syndrome, since it does not take place in

men or in normal pregnant or nonpregnant women, and since the steroid was not found in the urine of a case of adrenal tumor after removal of the enlarged gland. Report upon its physiological properties will be awaited with interest, as will comparison of such findings with those in other adrenocortical tumors.

PATHOLOGY

Most of the tumors are reddish-yellow and globular or ovoid, and have a thin, fibrous capsule. There may be invasion of the neighboring organs, the kidney being involved most frequently. The histology varies, although certain types often show a constant symptomatology.

In the male without endocrine symptoms, it was not possible even to guess from which cell structure of the adrenal cortex the tumor was derived. Section showed many large irregular cells with very large and bizarre-shaped hyperchromatic nuclei, often with mitotic figures and a pale, granular cytoplasm. These tumor cells showed a deep fuchsinophilic reaction in the cytoplasm with the trichrome stain, similar to the cytoplasm in the cells in adrenals from adrenogenital syndromes as described by Broster and Vines,¹⁰ which they suggested were characteristic of that syndrome. We have examined sections of an adrenocortical tumor sent to us by Dr. N. W. Roome of the Department of Surgery, University of Chicago. This tumor was removed from a man who had no endocrine symptoms. The sections resembled that of our male case, with perhaps fewer giant cells to the field. The main cellular structures of these two tumors resembled each other, however.

In the female without endocrine symptoms the tumor resembled more the zona fasciculata of the adrenal, although other sections in places resembled the other two layers. As a whole this tumor more closely approached those described as renal hypernephroma than did any of our adrenal tumors. Sections stained to determine fuchsinophilic granules showed that the cells contained them in only small amounts.

The tumors from cases with virilism varied from obvious carcinomas to what have best been described as adenomas. The cells of the malignant tumors were of relatively uniform appearance, although they varied in size. They were rather large and irregularly rounded or cylindroid, with well-defined cell membranes and a voluminous, faintly acidophilic cytoplasm. In some areas the cytoplasm was vacuolated, as if containing lipid. One of the carcinomas—from a case with marked sex changes—had a considerable proportion of cells that stained with fuchsin and showed a bright-red cytoplasm. In the others the propor-

tion was less marked. As a whole it appeared from careful study of these sections that the tumor cells resembled more the inner or reticulate layer of the adrenal than they did either of the other layers. Grollman³¹ suggests that such a layer may be concerned with certain phases of reproductive symptomatology, and may contain cell inclusions from the gonad which assume gonadal function in tumor growth. We have seen no evidence in our microscopic studies to support this suggestion. Broster and Vines¹⁰ described specific staining reactions of the cells of the adrenal cortex in cases of masculinizing syndromes and tumors. These we also encountered, but we have been unable to show the uniform predominate amount of such cellular staining as described by them. Further studies will be of interest.

The adenomas showed a large proportion of cells to have a cytoplasm filled with vacuoles, presumably lipoids, and clusters here and there of cells from the three layers of the cortex. It was impossible to derive from most of the vacuolated cells any suggestion as to their origin. The cells contained more or less the same amount of fuchsinophilic granules as was seen in controls.

Portions of the adrenals removed in cases of adrenogenital syndromes without tumors showed in most a cellular structure little changed from normal. Special staining in some cases showed an increase in cells with fuchsinophilic granules, but not to a predominant extent. It is possible that the portions of the adrenals removed by us may not have contained such areas, as described by Broster and Vines. We endeavored to remove a half or a third of a gland—first from what was demonstrated by air injection and x-ray to be the larger adrenal, and next from the thicker portion of that adrenal.

In one tumor sufficiently large for assay, Pfiffner³² reported that life maintaining hormone was not present in sufficient quantities for demonstration. Nor could Kurzrok²³ demonstrate any female sex hormone in this tumor. Although a steroid with androgenic activity has been isolated from the normal adrenal cortex, none has as yet been demonstrated in an adrenal tumor.

TREATMENT

Surgical exploration is indicated in tumor cases. Transperitoneal incision permits exploration of the entire abdomen, together with examination of the ovaries and the spermatic fascial planes where adrenal rests may occur. It also allows ligation of the vascular supply of the tumor before its manipulation, and theoretically lessens dissemination.

In the cases of tumors without endocrine symptoms the growths were so silent that they had

reached a large size before discovery. In the cases showing no demonstrable metastases the tumors were removed with only such technical difficulty as was caused by their size. Two of these patients made uneventful postoperative recoveries.

In the tumors with endocrine changes the operative risk appears to be better in cases with well-marked androtropic symptoms and with little metabolic change. This is especially true if a normal adrenal shadow is visualized on the opposite side and the presence of the second gland is confirmed at exploration. One such patient made an uneventful recovery. The patients with marked changes in metabolism are poorer risks. Three of our tumor patients went into acute adrenal collapse shortly after removal of the tumors. Two had well-marked metabolic changes with apparently normal-sized adrenal glands on the opposite side, while the third showed only a tiny shadow. One patient recovered with the help of multiple blood transfusions and saline infusions. Since she died later of metastases, there were evidently secreting tumor cells in these which may have influenced her recovery from the adrenal collapse. In the remaining 2 cases one patient died twenty-seven and the other thirty-two hours after removal of the tumor. Administration of a commercial preparation of life-maintaining hormone did not change the rapid fatal collapse in either case. Only slight and fleeting improvement followed blood transfusions and saline infusions. These cases showed a marked elevation of temperature, a very rapid pulse and a fall of the systolic blood-pressure readings to 50 or thereabouts. The patients were rational, observant and apparently comfortable up to a terminal convulsion. In both cases the tumors were small, one being a carcinoma and the other an adenoma. In the carcinoma the opposite adrenal was tiny. In the adenoma a normal-sized opposite adrenal was visualized but on autopsy it was shown to be thin and with atrophic cells. It has been suggested that in tumors of this kind, which are secreting large amounts of hormone necessary for plasma tone and function, the flooding of the organism by the tumor cells with such hormone or hormones causes functional and actual atrophy of the opposite adrenal. Support for this explanation has been advanced experimentally, especially by Ingle and Kendall,²² who showed that the administration of large amounts of cortin to a normal rat over a sufficient period of time produced atrophy of the adrenal cortex. In addition, they have demonstrated that such an atrophy can be prevented by the administration of a fraction of anterior pituitary extract which has high adrenotropic activity. Such experimental evidence explains why collapse is less frequent in patients with changes of the sex type,

and suggests in cases with metabolic changes a preliminary course of injections of fractions of such a pituitary extract, before operative removal of the tumor. Whether such injections will produce reactivity of functionless adrenal cells awaits demonstration.

Parts of the adrenals were removed in selected cases of adrenogenital syndrome without demonstrable tumors. In 2 of these cases, on account of obesity, operation was effected through the flank, the others were all explored by an anterior transperitoneal exposure, which allowed a thorough examination of all possible areas of adrenal rests as well as examination of the ovaries. The incision was made on the side of the largest adrenal and a section was removed through its densest portion. The deep location of the adrenal and its blood-vessel attachments makes such a procedure somewhat difficult in the obese, despite all types of mechanical aids. There was no postoperative mortality or complications in these cases.

RESULTS

Adrenal tumors without hormonal symptoms showed large, silent carcinomas that had been growing for a considerable period. Such tumors do not offer a high percentage of cures. Of our 3 cases of this type, 1 died without operative interference, 1 died of pulmonary and liver metastases one year after removal of the tumor, and 1 is alive, apparently without metastases, more than a year after operation.

Adrenal tumors with androtropic changes, if operated upon early enough, have a fair prognosis. They are usually of slow growth and remain encapsulated for some time. It has been our hope that air injections of the adrenals will demonstrate these tumors earlier than they are usually diagnosed. A number of operated cases have been reported as having had several years of follow-up without a recurrence. One we have followed for over three years without demonstrable metastases. Where metastases have occurred they have shown themselves by a recurrence of the syndrome. They have appeared most frequently in the lungs. There is usually a quick symptomatic recovery in these cases, especially in the menses and in the secondary sex organs—breast, clitoris, and so forth. The younger the subject, the more rapid is the recovery. That in the hirsutes varies, it is usually satisfactory except on the face, especially in those that have shaved. No improvement occurs in such fixed changes as dentition and closure of the epiphyses.

In the cases of adrenogenital syndrome without tumor, the administration of female sex hormone over varying times has in most cases given no lasting results. Following the bilateral injec-

tion of air around the adrenals in several cases of amenorrhea, we have, strangely, seen the return of menstruation but have found no explanation of the phenomenon. In cases submitted to exploration there has been some improvement in the symptoms after the exposure and removal of portions of the adrenal cortex, mostly in the menstrual sphere. Changes varied from a return of the menses to an increased regularity or an increased flow. In several cases there has been improvement of the body contour with a change in breasts and hips. There have been disappointingly few and slight changes in the hirsutism, with usually no change on the face. This has been one of the factors that has kept these women psychologically upset. We have seen no changes in the genitalia or in the voice.

One of the cases of tumor showed upon later air injection and x-ray an increase in the size of the remaining adrenal. A somewhat similar increase of the untouched adrenal apparently occurred following operative removal of a portion of the other adrenal in cases of the syndrome without tumor. A continuation of the study of these cases will show whether such a change will be accompanied by a recurrent increase in the symptoms of the syndrome.

SUMMARY

Adrenocortical tumors may occur without evident endocrine changes, but they are usually accompanied by characteristic hormonal changes. These are of three types: (1) changes in the secondary sexual characteristics toward masculinity in the female (androtropic) and rarely in the male toward the female (gynecotropic), (2) maturity in the young and more advanced age in the mature, (3) changes in the metabolism of plasma, fat and skin. In some cases one or the other type may predominate.

Similar endocrine changes called the adrenogenital syndrome, occur without any demonstrable tumor, but the symptoms are usually longer in duration, less pronounced and more variable, and not infrequently have a familial tendency and resemble the experimental intersexual animal or freemartin.

The adrenals may be visualized by x-ray after perirenal air injections.

The urinary sex hormones are usually excreted in amounts varying with the sexual changes, and seem to occur in both tumor and non-tumor cases. The excretion of male sex hormone is reduced following removal of a tumor, and apparently is also reduced following diminution of the adrenal cortex by operation when no tumor can be discovered.

A specific hormone may be excreted with some tumors.

The cellular structure of the tumors varies. The androtropic tumors most nearly resemble the reticulate layer. Fuchsin granules in the cytoplasm of cells have been demonstrated in both hormonal and non-hormonal tumors, but appear to be more predominant in the former.

The removal risk in cases of androtropic tumor is less than in those in which marked changes in metabolism occur, because in the latter, atrophy of the opposite adrenal is frequent. This atrophy has a suggested preoperative therapy.

Removal of the tumor produces a symptomatic cure but does not correct the fixed anatomic changes. The facial hirsutism often persists. When removal of a tumor is followed by metastases, the same endocrine changes recur that were present with the original tumor.

With operative decrease in the amount of adrenal cortex in non-tumor cases, there are some symptomatic changes. These are most marked in the menstrual sphere, with some changes in the body contour and psychologic state, and with little or no changes in the hirsutism, and in the genitalia or voice.

I am indebted to Dr. J. Bentley Squier for his kind encouragement, and my thanks are due to his staff and to the members of the other departments who have contributed so much to this study.

DISCUSSION

DR. CHARLES H. LAWRENCE. I agree that these tumor cases show several different types, and that we do not know as yet what kind of tumor goes with each type of symptomatology. I thought perhaps it would be interesting to report 3 cases in which the results are fairly well established, and tend perhaps to emphasize several of the things that Dr. Cahill mentioned.

Case 1 A girl of 13 years and 10 months was first seen in 1928. There was nothing of significance in the family history, except that the mother and one sister had had irregular and profuse periods. The patient had had an operation for acute appendicitis. She began to menstruate at 10 years and 8 months, which suggests that possibly some endocrine disturbance was already producing early maturity. During the next 9 months her periods occurred every 28 days, without pain. In June 1928 she menstruated normally, but had not done so since that time. During the first 6 months that we followed her she had anemia, but there was no change in her general condition.

One of the striking things is the relation between the development of symptoms and the time when it becomes possible to make an accurate diagnosis of adrenocortical tumor. Little attention was paid to her lack of menstruation until June, 1927, when masculine tendencies were first noticed—there was hair on the face and chest, and the voice became deeper. Her general health was excellent.

Physical examination showed a normal, well-developed female. There was acne on her face and back, which is a common symptom of adrenocortical tumor. There was dark, coarse hair on her arms, legs and back and her pubic hair extended up to her navel. Her clitoris was larger than normal. Rectal examination revealed a rather small uterus. There was no other pelvic abnormality. Nothing was shown by abdominal examination. The physical findings were otherwise normal. The laboratory examinations were all negative. The basal metabolic rate was normal. A kidney function test was normal. X rays of the skull, kidney and urinary tract showed no lesions. The eye grounds and visual fields were normal. Pelvic examination under an anesthetic showed no abnormality except a small, hypoplastic uterus.

We thought of a tumor of the adrenal cortex, a tumor of the ovary and possibly a tumor (basophilic) of the pituitary gland or one of the pineal gland, but there was nothing upon which we could establish a diagnosis. The patient was kept under observation for a year, and her condition remained essentially the same. At the end of that time she was seen by the late Dr. D. L. Jackson, who thought there was sclerosis of the ovarian cortices. Exploration revealed a small uterus with no endometrium. The ovaries were also small. There was retroversion of the uterus, the tubes were normal, the ovaries were smooth, with thickened cortices, and were packed with small cysts which were evacuated. The left kidney was normal on palpation, no abnormality of the right kidney was found, although the operator was not sure he had felt the adrenal. There was an uneventful recovery and no change in the symptoms. The patient was seen at 6-month intervals for the next 6 years, with no significant development until September, 1934, 5 years after operation. At that time she had developed moderate dyspnea and palpitation on vigorous exertion. This was the first new sign after the original development of masculinization. The systolic blood pressure, which had been normal, rose to 180. The renal arteries were not found to be narrowed. Hair appeared around the areolae.

An abdominal examination was negative. Pyelograms showed the right kidney to be larger than the left. The infundibuli and calices filled well. Neither Dr. G. C. Prather, who saw the x rays, nor Dr. L. R. Morrison felt that there was enough evidence of tumor to justify an operation. In April, 1935, x rays were again taken. The slight hypertension persisted. On palpation a definite mass was felt in the left flank. Pyelograms showed numerous areas of calcification in the region of the tenth lumbar vertebra and the tenth rib. There was a suggestive mass overlying the left kidney. The patient was operated on, and a tumor of the left adrenal was removed. It was completely encapsulated, and scattered throughout were small spicules of bone. Because of the size of the tumor it was necessary to remove both the adrenal gland and the kidney. Soon after the operation there was a fall in blood pressure. Many generous doses of Eschaun were given. The blood pressure stopped falling, and the level of the blood pressure readings seemed to depend upon the size of the doses of Eschaun. There is some difference of opinion as to the physiologic action of products of the adrenal gland now on the market, but Eschaun did seem in this case to have some effect in raising the blood pressure.

Before the patient left the hospital the umbre of her voice returned markedly to the feminine, and in 2 months it was back at normal. She began to menstruate in September. From that time she has continued to menstruate perfectly normally. This is interesting in the light of her ovarian lesion and the operative trauma to the ovary.

One year after operation examination showed some little gain in weight, which had been normal. Although there was a marked degree of hypertrichosis, this was not bothersome because the patient shaved daily. A year later it had practically disappeared. Only a little hair was left on the face.

It seems interesting that the tumor must have been there for at least 5 or 6 years before definite symptoms allowing diagnosis could be made, although clinically the diagnosis was determined before operation.

Case 2 A 24-year-old woman was first seen in March, 1934, in coma. The family history was negative and the past history not remarkable, except that she did not menstruate until she was nearly 16. Catamenia were regular

and normal for 2 years. She then developed menorrhagia with moderate secondary anemia, which persisted until the age of 21. At that time she had a flat sugar tolerance curve. Physical examination showed nothing remarkable except that the uterus, according to Dr F S Newell, was small. After 3 months of treatment with Antuitrin S the menorrhagia disappeared, it did not recur. From then until early in 1936 the patient appeared to be in perfectly normal health. Her current illness began while driving a car, when there was blurring of vision, and faintness. She was able to drive home, and after luncheon felt normal. The next night after retiring she went to her sister's room and returned to her own room. She was heard to fall, and when found, she articulated with difficulty and her speech was incoherent. After drinking a glass of orange juice she seemed as normal as ever, but did not remember going into her sister's room. For a week following the bout of fainting, she was well, and then fell into a coma, from which she could not be aroused.

Physical examination showed a normally developed individual. The blood pressure was normal. The pupils reacted to light. The reflexes and heart and lungs were normal. A mass was palpated which extended from the left caudal region to the left flank, and was resilient. The blood sugar was 40 mg per cent. The plasma carbon dioxide-combining power was 51 mg per cent, and the urine acetone 4+. The administration of 1000 cc. of 10 per cent glucose was started. The patient regained consciousness after 50 cc. had been given, and was able to answer questions before the dosage was completed. She had been aware of a prominence in the left upper quadrant for 2 or 3 months, but thought it was only a roll of fat. She was seen by Dr E L Young, who suspected a pancreatic cyst because of hypoglycemia and low blood pressure. Exploration revealed a large, bluish red mass, which was highly vascular. It extended backward into the posterior abdominal wall, and appeared to be fixed. A trocar was introduced, but no fluid was obtained. Removal was impossible and a small specimen was excised and the wound closed.

Examination showed the growth to be a cancer growing with moderate speed and originating in an endocrine gland. Whether it arose from the cells of Langerhans or the adrenal cortex was not known, but the latter was considered to be more probable. There was a slow and uneventful recovery from the operation.

The blood sugar varied from 41 mg per cent to lower levels. There was a later reading of 61 mg, and the last one taken was 60 mg. The low readings were not always accompanied by clinical symptoms of hypoglycemia. The blood picture was normal. Determinations for urinary prolactin and estrin were negative. Menstruation continued for 2 months and then ceased, and has not been re-established. X ray treatment was given, during it there were no major hypoglycemic attacks, although the patient occasionally felt dizzy.

On July 10, 1936, the x ray treatment was discontinued. In October coma frequently recurred, but it invariably responded to intravenous glucose, the blood sugar content at that time was 110 mg per cent. Acne, which was present at operation, grew steadily worse, it involved the entire face, chest and back, and there was also marked acanthosis of the axillae. The tongue became thick, and so did the subcutaneous tissues of the shoulder and neck. This condition did not resemble simple obesity. The blood chemistry was entirely normal. Hormone assays were again done, but no signs of prolactin or estrin were found. Other x rays were taken but no metastases were found. On October 13, 1936, a second attempt was made to remove the tumor, by Dr W E Ladd, who used a flank in-

cision, but this was found to be impossible. Diagnosis of a tumor of the suprarenal cortex was confirmed.

There then occurred a number of interesting developments. For 36 hours after the operation the temperature rose to 104.4°F, and the pulse from 120 to 180. The blood pressure fell to 120/50. The patient became unconscious but was revived after intravenous glucose. The blood picture and the physical examination were both normal. On the 3rd day after operation there was marked improvement, the temperature was 101°F and the blood pressure returned to normal. During the next 2 weeks there was marked general improvement. The subcutaneous thickening had almost disappeared. The acne and the acanthosis also practically disappeared. The patient left the hospital in good condition, and no more hypoglycemic attacks occurred.

A month later the patient's condition grew worse. Her systolic blood pressure rose to 190, and she developed edema of the lower legs. Dullness in the lower abdomen was occasionally demonstrable. Attacks of coma became more and more frequent. During one of them delay in preparing glucose forced us to give 1 cc. of adrenalin. The effect was surprising, and before the glucose could be brought into action the patient recovered. Since that time we have repeated the adrenalin, and find that as little as 0.3 cc. of a 1:1000 solution restores the patient to consciousness just as efficiently as does glucose.

This is an interesting endocrine situation, one which we can only explain by saying that the hypoglycemia is not due to exhaustion of sugar reserve, but to a break in the chain which renders it impossible for her to take glycogen from the liver when the blood sugar content gets too low. Adrenalin seems to fuse the chain again, and the blood sugar becomes normal.

The patient showed very little loss of strength. In January, 1936, she had another exacerbation. After consultation with Dr E D Barringer and Dr James Ewing she was sent to New York and given radium packs, since then she has had x ray treatment. On April 9, 1936, I examined her because of failing vision. At that time examination of the eye grounds showed only moderate sclerosis of the arteries but no exudate or hemorrhages. Since then, I have heard, her vision has improved. The lesion is probably circulatory. I have not seen reported in the literature any disturbance of carbohydrate metabolism like that which this patient shows.

Case 3. In this case the clinical picture was difficult to distinguish from that of pituitary basophilism. The patient, a 30-year-old white woman, entered the hospital in 1934 because of blurring of vision of 18 months duration. There was a history of polyuria and nocturia of 9 months duration, and of undue fatigue for several years. The patient had always bruised easily. There was an increased growth of hair the previous year, the new hair being red and fine (she was red headed). One of her brothers had died of diabetes. Otherwise the family history was normal, as was her past history. Her periods started at 11—a bit early. They were regular until 1931, when they were irregular for a month and then stopped, the patient's voice became harsh and her hair coarse, and she gained 25 lb in weight. At that time she was seen at the Lahey Clinic and was found to be overweight and nervous. Her heart was moderately enlarged and the aortic second sound was accentuated. The blood pressure was 240/130. The pelvis was negative. There was edema of the lower extremities. The eye grounds showed no abnormality. The nonprotein nitrogen was 32 mg per cent. The blood picture was essentially normal. The specific gravity of the urine varied from

1005 to 1014. A diagnosis of primary hypertension was made.

During the next few years there was increased fatigability, and for the last year before admission it was necessary for the patient to remain in bed a day or two at a time. Blurring of vision increased steadily, and there were fixed spots before the eyes for 2 weeks before admission. Reading was difficult. The eyelids became puffy and it required effort to hold the eyes open. On admission there was an increase of the hair on the face. The skin was black and blue over the lower legs and ankles and the feet were swollen. There was reddening of the facial skin. Obesity was localized in the abdomen and breasts. There was pitting edema of the legs. Reddish-blue striae occurred on the medial aspect of the thighs. There was an increase in hair. The fundi showed characteristic choking of the disks, with exudation in the right eye. The lips were cyanotic, and the skin was dry and scaly.

There was much discussion in the hospital as to whether there was a basophilic or an adrenocortical tumor. The neurological examination was negative. The patient showed a tendency to increased production of red blood cells, and had a hemoglobin of 103 with 5,500,000 red cells. The blood cholesterol was also high. The non-protein nitrogen was 52 mg per cent. The glucose following a tolerance test, showed a high curve regaining 246 mg in half an hour. The curve remained high (172 mg) at the end of the test. The urine showed normal dilution and concentration, with a phenol sulfonphthalein of 49 per cent. The albumin was constant, between 1.0 and 1.5 per cent on numerous examinations. The sediment showed many finely granular casts. A pyelogram was negative, and x-ray photographs of the skull showed no evidence of tumor. The electrocardiogram was normal. The blood pressure was 200/160. The basal metabolic rate was normal. The general consensus myself dissenting, favored a diagnosis of malignant nephrosclerosis with pituitary basophilism. I insisted on a diagnosis of adrenocortical tumor until Dr. F. H. Lahey operated and removed a left adrenal tumor. The blood pressure fell to 120 and continued to fall in spite of intravenous injections, including Eschschin, and the patient died. Postmortem examination showed absence of the left adrenal gland and extreme atrophy of the right one which weighed less than 0.5 gm. The capsule was thickened and the medulla almost absent. A few cortical cells remained. The right gland contained cysts as well. Microscopic examination revealed an adenocarcinoma. Serial sections were made of the pituitary, but careful search failed to show any signs of basophilism.

These three cases bring out some interesting considerations regarding the endocrine glands. In the first case masculinization was marked, in the second, there was little masculinization but an odd change in carbohydrate metabolism in the third, there was masculinization, but of a moderate type. All three patients had adrenocortical tumors. The very early onset of menstruation in the first case and the definitely late onset in the second suggest that the excess of hormone may have been due to a pituitary factor long before the clinical picture had developed.

A PHYSICIAN: What was the pathological report in the first case?

DR. GEORGE C. PRATHER: Carcinoma simplex.

DR. FULLER ALBRIGHT: I should like to ask one question. We are indebted to the Presbyterian Hospital in New York City not only for knowledge concerning increased and decreased function of the adrenal gland, but also for the

fact that Loeb first called attention to the fall in sodium in Addison's disease. Have you carried out studies in order to see whether any abnormality in sodium accompanies excess adrenal function?

GROLLMAN: I believe that the androgenetic hormone is produced by another cell in the adrenals is entirely theoretical, in that the hormone is assumed to come from some remnant which yields masculinizing hormone. If this were the case, we should not find atrophy of the other gland. To do so would be strong evidence against Grollman's theory.

I was very much interested in the mention of polycythemia and decreased blood volume. We have found these at the Massachusetts General Hospital; they may constitute a very important clinical point. Many patients die in a state of shock after an operation on the adrenals. This has been explained by the fact that the other gland has atrophied. It is probable however, that some of these patients succumb to shock due to the decreased blood volume.

I was hoping to hear something about bones, for we are very much interested in this subject. The osteoporosis which occurs in some of these cases is significant. In 1 case the presenting symptom was a decrease in height. The patient eventually died from an adenocarcinoma and stones in the kidneys. There is an increased excretion of calcium in the urine in spite of the normal blood calcium and phosphorus. This patient showed a perfectly normal parathyroid post mortem so that the increase in decalcification cannot have come from that. We think that bone disease is due to senile osteoporosis, after all, it consists very largely of increased precocity. There is heightened sex development, and also mental and physical development. The same thing happens if there is an increase in secretion by the adrenals, thus, precocity in the adult results in senility, which, in turn, causes changes in the bones.

DR. JOE V. MEIGS: I should like to ask about the second slide in the case of adrenocortical tumor, may this not have been a chorioepithelioma, and was not the man demasculinized? It looked to me like a chorioepithelioma, and if it were, such a diagnosis would be very interesting. Secondly, in masculinizing tumors in the female the hormone is produced separately by the lining cells, which are present and can be seen in the arrhenoblastoma. They stain with Sudan III. It may be that the clear cells were the cells of this tumor and that the masculinizing hormone recovered in the urine was produced by them.

DR. GEORGE W. HOLMES: The roentgenological problem is to establish the presence or absence of these tumors. In order to do that one must have the best quality of films. Whether we can improve the technique by newer methods is somewhat problematic, but it is expected that we may do so with fast machines and better focus points. It may be possible for us to help more than we do at present. We depend upon the air injection, which must be properly done otherwise the x-ray is of no value.

The next problem is the interpretation of the film after we have developed it. The adrenal gland is of many shapes and sizes and when we look at x-ray pictures of it we see only the projection of the shadow in one of many planes. It is very difficult for us to describe the gland. Dr. Cahill has been able to diagnose accurately some of the larger and more characteristic tumors. I fear we shall always have trouble with the smaller and less characteristic ones. I have not had an opportunity myself to carry on this work, but I have seen others do so. Dr. Richard

Schatzki is here and can probably give a better interpretation than I can.

DR. RICHARD SCHATZKI I should like to ask two questions. Has Dr. Cahill any standards as regards the size of a normal adrenal x ray picture? We have had decided difficulty with borderline cases, and described one medullary tumor as an upper limit of normal, whereas it was abnormal. Has he used lateral films in order to demonstrate the thickness of adrenal tumors? We have tried them unsuccessfully.

DR. WILLIAM C. QUINBY I want first to compliment Dr. Cahill on his adept handling of a very abstruse subject. He has not described a single type of case tonight. He has described cases of the adrenogenital complex in which there apparently was no lesion in the pituitary, and in some cases I do not feel that he has succeeded in demonstrating adrenal lesions either. This is a very complicated subject, and one on which we have been privileged, tonight, to hear the most advanced opinion.

To take up the subject serially, the injection of air around the kidney in order to demonstrate either renal or adrenal tumor I tried out a number of years ago. It is not an accurate method of examining either type of tumor, especially the adrenal. Everything depends upon the situation in the given case. In the first place, the injection must be made into the renal fossa. There are no results if it is made in the substance of the psoas muscle. The amount of air injected must be in excess of that which one would ordinarily inject for the demonstration of renal tumors. Furthermore, air is much better than oxygen, and nitrogen is better than air, the point being that one should inject a gas which is slowly absorbed, and make x ray observations at stated intervals afterward. One usually gets a very confusing picture of either renal or adrenal tumor within five or six hours after injection of atmospheric air around the kidney or into the renal fossa. The injection in every case, so far as the procedure goes, is similar. It makes no difference whether you are trying to outline the adrenal or the kidney.

The interpretation of x ray films is still somewhat questionable. The roentgenologist is doing his best to help us, but we must make many more injections before standardization becomes possible. The opinion in any one case may be either for or against the possibility of a tumor. A good many cases in which the adrenal is definitely at fault, as has been shown by Dr. Cahill, do not show a definite enlargement of the adrenal in the x ray films. Similarly, conditions in the pancreas or the parathyroids can well cause overfunction, which produces the symptoms of disease, without very much in the way of a demonstrable tumor. It is absolutely impossible in cases of hypoglycemia that have been successfully operated on, and that have been demonstrated by surgeons. An analogous situation probably exists in regard to the cortex of the adrenal gland. I am in doubt as regards tumors of the medulla, which are quite different in their clinical manifestations. What we are discussing, as I understand it, is tumors of the cortex of the adrenal. Undoubtedly a good many start or remain as adenomas, and only later do they become definitely invasive neoplasms. To be able to demonstrate such a condition in the adrenal in the early stage is beyond the reach of any roentgenological procedure that I know about. We must therefore depend largely on clinical manifestations. The reports of increasing numbers of patients—and, as Dr. Cahill tells me, they are large—will eventually bring a certain amount of clarity to a state of mind which in my opinion is still chaotic.

In the first place, we must eliminate tumors of the pituitary, because we know that this gland is probably primarily at fault in a good many variegated conditions affecting the secondary sex sphere. These have largely been excluded by x ray of the sella turcica. We next come to the question of what sort of adrenal the patient has. Within our present limitations we must be willing to investigate the adrenal by open operation. There are definite instances in which the clinical picture is characteristic, in spite of the fact that we may not be able to demonstrate any very striking differences from the normal through such procedures as the injection of air.

I call to your attention also the fact that, speaking clinically, most tumors of the adrenal cortex, so far as we know them today, have as their clinical effect an increase in masculinization. In women the changes lie in the direction of virilism. In men they lie in the direction of precocious puberty or hypervirilism. In many such cases the condition can be made clear by the pediatrician. My experience has been with individuals in whom the diagnosis should have been made while they were under the care of the pediatrician, not that of the urologist.

Two or three years ago I reported a case in which a child had been born and bred under the best possible circumstances and had been known to be precocious from his second year of life. He had gone through school at an early age, and was prematurely developed in body as well as in mind. He received no medical attention until, at the age of ten, while running a race, he had an acute abdominal crisis. Investigation revealed an abdomen full of blood, and it was later found that the free hemorrhage had been caused by rupture of an adrenal tumor as large as the patient's head. There were present hypertrichosis, acne, a decreased amount of sugar in the blood, hypertension, and every other condition needed for a diagnosis of adrenal tumor, but in that day it was not appreciated that the child probably had an adrenal tumor which eventually became malignant, and which might have been removed before it had become invasive, his life thus being saved. There was a perfectly normal adrenal on the other side. In many other instances, of course, the other adrenal is atrophied.

DR. CAHILL (closing) I am in accord with Dr. Quinby's statements in their entirety. I have taken special care to limit my statements to known facts. I gave no hypotheses and no theories, and I said that we used only the tools available at present in trying to arrive at a diagnosis. In 27 of the cases we diagnosed tumors in only 6, although the others had symptoms. I operated on many of them, following Dr. Quinby's idea exactly.

In making x ray pictures we take them serially, injecting air one day and taking them the next, we then repeat the procedure, looking for a lead, and that is all we do. The technic is imperfect, but at present it is the only means we have of detecting adrenal tumors.

In answer to one question, collapse occurs in some cases from hemorrhage into the abdominal cavity, in other cases I believe that collapse and death are the results of handling of the adrenal gland. In about 15 per cent of the entire population only one adrenal gland is functioning normally.

There are many functions of the adrenal gland, and many hormones. As shown by some of the reported cases, there are hormones producing masculinization and maturity, the latter is a tremendous force in the body, closing off the epiphyses and producing old age rapidly. There is the famous case in France of a patient who advanced from childhood to adulthood, became a father, and died of old age within ten years.

Dr Loeb studied all our cases with us. We could not demonstrate any abnormality in the sodium balance, and apparently there was none. In the adrenal cortex there must be cells with many different functions, and the final result depends upon the interrelation of the whole. We are just trying to make hypotheses in the direction in which it goes. We have tried to determine the particular change in salts which produces collapse. This factor is apparently known in animals, but whether it exists in human beings we are not aware. A woodchuck whose kidneys and adrenals are removed can live for four to six weeks in the winter, but only two days in the summer. What has hibernation to do with such things? The question is a fascinating one. I did not indulge in those phenomena but only

tried to call attention to the observations which seemed unassailable to ourselves.

In the second slide, it is true, the cells resemble those of a chorioepithelioma. In our experience these produce gynecomastia and large amounts of prolactin A. In fact, one can make the diagnosis of testicular tumors according to the amounts of prolactin.

What constitutes a normal x-ray picture I do not know as yet. I have made over one hundred so as to see what improvement can be made in present methods, and to gather experience and determine whether the glands are normal or abnormal. I admit that we may never get anywhere, but we are only using these tools to see how far we can go. We have not had very much success with lateral films.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 24191

PRESENTATION OF CASE

First admission A sixty-two-year-old Russian Jewish woman entered the hospital with the complaint of fluid in the right chest of three years' duration.

Seventeen years before entry the patient began to have a persistent nonproductive, brassy cough and felt that there was "something in her chest that should be coughed up." She had no hematemesis, hemoptysis, dyspnea, orthopnea or peripheral edema. She was treated by her physician for six months without appreciable benefit and at the end of that time entered an outside hospital where by x-ray a large substernal mass was found. Bronchoscopy showed evidence of marked pressure on the trachea at its bifurcation. A biopsy of an axillary gland showed no evidence of metastasis. She refused operation and went to another hospital where she was given a course of radiation lasting over a period of many months. This gave her prompt relief, and she had no symptoms until three years before entry, when she had pneumonia which lasted about a month. She lost about 25 or 30 lb. in weight and did not seem to recover completely from the illness. She had difficulty in breathing and orthopnea, and her physician found a right-sided pleural effusion, which he tapped. From that time until the time of entry she had repeated reaccumulations of fluid, which were tapped on nineteen occasions. As the fluid accumulated she had dyspnea, orthopnea, some distention and tenderness in the region of the liver and spleen, but no peripheral edema. Her appetite was rather poor, but her stools were normal, and there was no tendency to constipation. She had no other significant symptoms except weakness and a total weight loss of 40 lb. during her entire illness. One year before entry she was given another course of radiation by deep x-ray, which was carried out over a period of nine months. The treatment had no apparent effect and did not decrease the size of the mass. The fluid withdrawn at the various taps was yellowish in color and on one occasion bloody, search for tumor cells in it was negative. Guinea-pig tests were negative. Her past and family histories were entirely negative.

Physical examination revealed a fairly well-

developed but poorly nourished woman in no great discomfort. There was marked dilatation of the superficial veins on the upper arms and anterior aspect of the chest. In the lower anterior part of the neck a smooth, symmetrical, moderately firm mass was palpable extending down into the neck. There was dullness over the lower two thirds of the right chest, with practically absent breath sounds at the right base. A few moist rales could be heard at the left base. The heart was slightly displaced to the left, and there was a harsh apical systolic murmur. The blood pressure in the right arm was 195 systolic, 80 diastolic, in the left arm 190 systolic, 80 diastolic. The liver edge was palpable two fingerbreadths below the costal margin. There was no edema of the extremities.

The temperature was 98°F, the pulse 80. The respirations were 22.

The urine examination was negative. The blood showed a red-cell count of 5,090,000 with 80 per cent hemoglobin, and a white-cell count of 7700 with 75 per cent polymorphonuclears. The Hinton test was negative. An attempt to determine the basal metabolic rate was unsuccessful because of lack of co-operation by the patient. An electrocardiogram showed slight tendency to left axis deviation and T waves which indicated a possible digitalis effect.

X-rays of the chest showed a large fairly symmetrical mass occupying the upper mediastinum and displacing the esophagus to the left and the trachea to the right. The trachea was considerably narrowed in the region of the thyroid, but neither it nor the esophagus showed any evidence of intrinsic disease. The mass lay chiefly in front of the trachea but extended posteriorly to press on each lateral wall. The margins of the mass were smooth, except for a slight nodular projection opposite the arch of the aorta. The lower two thirds of the right lung were obliterated by homogeneous dullness. The upper margin of this shadow was convex upward suggesting a mass surrounded by fluid. The heart and mediastinum were markedly displaced to the left, the displacement being out of proportion to the amount of fluid present. The left lung was clear, but there were fine linear areas of density extending outward from both lung roots. Films brought in by the patient taken over a period of two years showed very little change in the appearance of the mediastinal mass.

On the seventh day a right chest tap was done, and 750 cc. of amber blood-tinged fluid was removed. Its specific gravity was 1.010. No tumor cells could be identified in the fluid, and aerobic and anaerobic cultures and a smear were negative for bacteria. An x-ray of the chest taken after the tap showed no evidence of tumor in the right lung.

She was discharged unimproved on the eleventh day.

Last admission (four months later) During the interval her symptoms continued unchanged, and it was necessary for her to have repeated chest taps. She lost about 10 lb. more in weight.

Physical examination revealed a poorly nourished, orthopneic woman. The physical findings were essentially the same as on the previous entry. The blood pressure was 150 systolic, 90 diastolic, and pistol-shot sounds were heard over the brachial and femoral arteries. No enlarged lymph nodes were palpable. There was slight pitting edema of the legs, more marked on the right.

The temperature was 99°F., the pulse 104. The respirations were 25.

The urine examination was negative. The blood showed a red-cell count of 4,400,000 with 80 per cent hemoglobin, and a white-cell count of 3700 with 80 per cent polymorphonuclears.

She was found dead in bed on the evening of the second day. She had been seen two hours previously, and at that time her condition seemed to be as it had been on entry.

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES: These films cover a period of a little over six months and show what is described in the text. There is certainly a mass here, and the esophagus is obviously displaced to the left. One might question whether the trachea is actually displaced to the right, it may be, but there is quite a variation in the position of the normal trachea. A mass which displaces the trachea in one direction and the esophagus in the other would have to lie between the two, and one would have to think of an aneurysm. I do not see any indication of that here, however, we have a fairly good view of the aorta, and it does not seem to be dilated or deformed in any way. Aneurysm of a branch of the aorta is certainly rare without some change in the aorta itself. The lesion appears to be noninfiltrating.

DR. FREDERICK T. LORD: Where is the x-ray without the fluid?

DR. HOLMES: This shows the area of the tumor mass, and it is pretty free from fluid. There is a lot of fluid at the bases, however.

DR. LORD: It says in the record. The trachea was considerably narrowed in the region of the thyroid.

DR. HOLMES: This first film does not seem to show much narrowing of the trachea. The patient had a good deal of radiation and some of these changes may be due to fibrosis. In this second film, however, the trachea is narrowed in the upper portion. The mass lies more anterior than

posterior, although it occupies the whole upper part of the chest.

DR. AUBREY O. HAMPTON: One of the most interesting features in the case is that the size and shape of the mass have not changed appreciably in two years.

DIFFERENTIAL DIAGNOSIS

DR. LORD: The history suggests an origin in the mediastinum, later there was enlargement which resulted in the tumor that appeared in the neck. The mass did not respond to x-ray in the second instance, it may have in the first. It was probably not a lymphoblastoma. It was almost certainly not a malignant neoplasm originally but a benign tumor of some sort might have become malignant. Of course the difficulty which arises under such circumstances is to determine the nature of the process. There are many chances. It might be a fibroma, lipoma, chondroma, myoma, cyst adenoma, thymoma or, more plausibly, a substernal goiter. It might be an aneurysm, but the negative Hinton renders this unlikely.

Let us consider for a moment the pleural fluid. The specific gravity of such samples is often of considerable value. This one at 1010 was low. That is suggestive of a passive transudate rather than an inflammatory process but it might nevertheless be due to cancer. Some of the fluids secondary to cancer may be low in specific gravity.

This may be a substernal goiter. It is not an aneurysm, from what Dr. Holmes said about the x-ray and because of the negative Hinton test. Echinococcus cyst is a possibility, it cannot be dismissed. Then there is the dermoid, or the teratoma, and I feel confident that if I keep on making this diagnosis I shall eventually be right according to any system of chances. It is a little suggestive that she had a bronchostenosis because of the practically absent breath sounds at the right base, in spite of the fluid. Fluid does not give absent breath sounds. They may be very much diminished, but they are likely to be bronchial. We do not know whether these were bronchial. I cannot escape the thought that she might have bronchostenosis of the right lower-lobe bronchus.

It is of considerable interest to speculate as to the nature of the fluid. It might be tuberculous but she had no evidence in the lung of a tuberculous process, it is unlikely. It might be secondary to cancer, or to chronic passive congestion from pressure on the azygos vein. If this is a neoplasm which started as a benign growth and has now become malignant, the chances would seem to be that this fluid is of carcinomatous origin. Do intra-thoracic tumors, either benign or malignant, give

rise to pleural fluid by pressure and not always by extension of the growth or metastases? So far as my experience is concerned, pleural fluid in connection with tumors has invariably been due to the latter, so I am disposed to guess that the fluid is of such origin, but it would be of considerable interest to know whether it could follow passive congestion.

In addition to these matters she had hypertension, and a wide pulse pressure—195 systolic, 80 diastolic. Such a high pulse pressure with a pistol-shot sound over the brachial and femoral arteries is suggestive of aortic regurgitation. The harsh apical systolic murmur suggests mitral insufficiency. The immediate cause of death is hard to explain. She had hypertension. At sixty-two one should think of arteriosclerosis and cerebral hemorrhage or coronary disease. I submit as diagnostic possibilities a mediastinal dermoid or teratoma and carcinomatous pleural effusion.

DR TRACY B MALLORY: There is always a wide field for suggestions in these mediastinal tumors. Dr. Churchill, have you anything to add?

DR. EDWARD D. CHURCHILL: I saw this patient and know the results of the autopsy, so all I shall add is that I was brave enough to recommend operation at the time of the first admission and to recommend her second admission with a view toward reconsideration of operation which had been refused the first time.

DR. LORD: What did you think it was?

DR. CHURCHILL: Our reasoning was a good deal like yours in relation to the chest fluid. We thought that it was suggestive of cancer, but with the long duration of this illness and also that of the pleural effusion we decided that there was a possibility that it could be simply a substernal goiter and that her only chance was to treat it as such and operate through the neck to see if it could be removed. The whole thing might have been due to simple substernal goiter, the picture being confused by the radiation therapy which she had had before we saw her.

DR. BERNARD JACOBSON: I think the statement about the diastolic pressure being 80 does not do justice to the situation. We could hear the diastolic sounds going down to about zero, but never heard a diastolic murmur in the heart. At the time when we did not know anything about the diagnosis of the mass we were still puzzled about the accumulation of the fluid. I should like to ask Dr. Lord if he has any other suggestion for the extremely large pulse pressure.

DR. LORD: I do not know of any relation between pleural fluid and high pulse pressure.

CLINICAL DIAGNOSES

Mediastinal tumor
Pleural effusion, right
Hypertensive and arteriosclerotic heart disease

DR. LORD'S DIAGNOSES

Mediastinal tumor, dermoid or teratoma?
Pleural effusion, secondary to cancer?

ANATOMICAL DIAGNOSES

Substernal colloid goiter with compression of innominate veins
Hydrothorax, bilateral
Pulmonary atelectasis, left
Pleuritis, chronic fibrous, bilateral

PATHOLOGICAL DISCUSSION

DR. MALLORY: What we found at autopsy was an extremely large substernal goiter. The entire thyroid was enlarged and was made up of multilobular masses of which one in particular projected down through the suprasternal notch and appeared to press upon the innominate vein and the innominate artery. Histologically, it was a benign colloid goiter. There was virtually nothing else found at autopsy except an effusion. At the time of death there was nearly 3000 cc of fluid in the right pleural cavity, and about 800 cc in the left. The heart, in spite of the blood pressure, was practically normal. It weighed only 310 gm, certainly a minimal degree of hypertrophy, and the valves were entirely negative. How this woman's peculiar pulse pressure is to be explained, I have no idea. I was inclined to believe there was enough pressure upon the great veins in the mediastinum to account for the accumulation of fluid.

DR. WYMAN RICHARDSON: Why did she die?

DR. MALLORY: There was no explanation why death should have been so sudden. Her vital capacity must have been reduced. She had nearly 4000 cc. of fluid in the chest. It is only fair to point out that very large amounts of pleural fluid can accumulate within a very few hours, so that that does not necessarily mean negligence when the physician has found no evidence of it. We have seen cases which have been checked by x-ray examination where as much as 4000 cc of fluid has accumulated within twelve hours.

DR. HOLMES: Did the lungs show any evidence of fibrosis from radiation?

DR. MALLORY: We noticed some fibrosis of the pleural surfaces, but we did not examine them particularly with that in mind, so we may have missed diffuse intrapulmonary changes.

DR. GEORGE W. W. BREWSTER: Could the goiter

have been removed by operation at any time?

DR. MALLORY It certainly could have been removed during the first fifteen years, possibly on the first admission.

DR. HOLMES Do we know how much radiation she had?

DR. JACOBSON There is some statement about it in the record. She apparently had regression of the substernal goiter after the first x-ray treatment seventeen years previously.

DR. MALLORY You would not expect x-ray treatment to have much effect on a colloid goiter, I should imagine.

DR. HOLMES Not if it were colloid. I think it is justifiable to treat if you have a correct diagnosis. If you knew that the patient had intrathoracic goiter and operation were refused or not considered justifiable, the proper amount of radiation to the gland would be considered good treatment, but the trouble in all these cases is that you are never sure of the diagnosis. Radiation may be the wrong thing to do.

CASE 24192

PRESENTATION OF CASE

A seventy-year-old, white, Canadian foreman entered the hospital with the complaint of loss of function of his legs of three weeks' duration.

He was entirely well until three months before entry when he wrenched his back while lifting a crate of eggs. He had a sudden sharp pain localized in his left hip which lasted for a few minutes. He finished his work that day but had difficulty in walking home because of stiffness and soreness in his legs. However, his legs were not numb. These symptoms persisted, and he remained away from work for five weeks. At the end of that time there was only a little residual soreness. Two weeks later, five weeks before entry, he was struck in the side and pinned against a wall by a cart containing twenty-five crates of eggs. The ribs of his right side were damaged but not severely enough to keep him from work. His physician strapped his chest, and in the course of a few days the pain wore off. However, at the time of entry he still had pain in his side when he laughed or coughed. Three weeks before entry he began to have dull pain in the upper lumbar region when he sat down, but which disappeared on walking about. About a week later he began to have a dull heavy feeling in his left foot, in the course of three days this spread to both legs with almost complete loss of their function. If he attempted to stand, his knees buckled under him. There was no pain or coldness in his legs, but they felt heavy and numb, with prickling sensations in the

feet. He also had a scalding sensation in the middle of his back when he became overheated, which radiated in a band around his chest. For the week before entry he had involuntary jerking and twitching movements of his legs, which sometimes kept him awake at night. About four days before entry his feet became somewhat swollen. He had no other symptoms of any kind. At the time of entry he was still able to move both legs. He had not lost any weight.

His first wife and two of his siblings had died of tuberculosis about forty years before his present illness. His past history and family history were otherwise negative.

Physical examination revealed a well-developed and nourished man in no apparent discomfort, showing occasional involuntary flexion of his legs. There was marked tortuosity of the retinal arteries, and edema of both lower legs. The general physical examination was otherwise essentially negative. The blood pressure was 170 systolic, 70 diastolic. Neurological examination showed an area of hypesthesia ending at the level of the second lumbar vertebra with absent position and vibration sense in both ankles and feet. Both legs were spastic, and voluntary muscle contractions were weak. The leg reflexes were hyperactive. There was bilateral ankle clonus, and bilateral Babinski signs were present. The examination of the upper part of the body and of the upper extremities was negative. Rectal examination was negative. The prostate felt normal in size and consistence.

The temperature was 98.6°F, the pulse 80. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 4,100,000 with 90 per cent hemoglobin and a white-cell count of 10,900 with 69 per cent polymorphonuclears, 26 per cent lymphocytes and 5 per cent monocytes. The serum protein was 7.8 gm per cent, and the blood Hinton test was negative. A lumbar puncture showed an initial pressure of 50 mm of water, with respiratory oscillations but without pulse oscillations. Jugular compression elevated the pressure to 60 mm and abdominal compression elevated it to 210 mm. The lumbar spinal fluid was yellow, contained 1200 mg per cent of protein, and had a goldsol curve of 0000022553. A cisternal puncture showed an initial pressure of 80 mm., with normal dynamics except for an elevation to only 110 mm on abdominal compression. The cisternal fluid was clear, contained 12 mg per cent of protein and 83 mg of sugar, and had a 0000000000 goldsol curve. The spinal-fluid Wassermann test was negative. X-ray examinations of the spine showed disappearance of the right pedicle of the eighth dor-

sal vertebra The right side of the body of this vertebra was deformed and less dense than the left side There was thickening of the soft tissues opposite the least dense area There was extensive spur formation about the margins of the lumbar vertebrae, and the right twelfth rib showed evidence of an old fracture Lipiodol injected into the cistern descended to the level of the seventh dorsal vertebra where it met a definite block, the column ending in a pointed extremity The film showing this also showed partial destruction of the pedicles of the seventh and eighth vertebrae and slight wedging of the body of the eighth

On the sixth day he began to have abdominal distention and retention of urine Catheterization yielded 750 cc of urine An operation was performed on the thirteenth day

DIFFERENTIAL DIAGNOSIS

DR SUMNER M. ROBERTS The sudden pain in the patient's left hip is perfectly consistent with a back strain To the layman the hip region includes the whole buttock as a rule, and pain in the buttock, if this is where it was, is a common accompaniment of low-back injuries Soreness in both legs is not so common following injury, but often there is soreness in both buttocks and upper thighs as the result of a fascial strain of the low back His improvement under a five weeks' rest is again consistent with a simple strain

By damaged ribs I suppose they mean broken ribs We are taught that ribs heal in four weeks, but discomfort after five weeks is not unusual, particularly in an elderly man, and injury to the rib cartilages persists much longer than this

He had dull pain in the upper lumbar region, which was improved by walking This is a common story with any mild irritation, infectious or mechanical The patients feel better while walking about, but they pay for their activity later by stiffening up when they sit down So far, except for the soreness in both legs, the history suggests nothing unusual that might not happen to any elderly man with a back strain

Then things began to get serious, and there was rapid loss of power in the legs, with sensory disturbance The scalding sensation in the mid back with radiation around the chest is the first sign we have of any trouble higher than the low-back region His feet became swollen Does this mean any cardiac or renal condition? Not necessarily Swelling and edema are common accompaniments of paralysis, especially of the central-nervous-system type It is particularly common following cerebral accidents

From the history alone we can tell that he has some lesion in the spinal cord or close to it and pressing upon it, with preliminary symptoms simulating a back strain and possibly aggravated by his crushing injury Can he have tuberculosis? This can be dormant for some time with a fairly sudden onset of symptoms, and we know that tuberculosis can cause cord compression This disease is rare at seventy, and all the cases I have seen at this age have had a long history of previous tuberculous trouble in the back A fresh focus at this age is so unlikely that this diagnosis can be ruled out

Paget's disease can cause partial collapse of the vertebrae, but seldom, if ever, results in neurologic symptoms Even if Paget's disease is picked up later on physical examination, I do not think it is the cause of his trouble Senile osteoporosis can cause the collapse of multiple vertebrae The symptoms sometimes are very slight and sometimes very severe Again, however, this condition does not cause cord compression

The most likely explanation for his symptoms is a tumor of or close to the cord and causing pressure symptoms His age and previous good health both support this conjecture The family history of tuberculosis forty years ago does not alter my opinion as to the unlikelihood of this disease's being the cause of symptoms

The general physical examination was negative The apparent normality of the prostate is important Neurological examination suggests trouble at the second lumbar vertebra or a little higher There was nothing neurological to suggest trouble in the dorsal region or to explain his radiating chest pain His general good health is against any generalized metastatic lesion, at least involving important organs The physical examination therefore helps us to localize at least one level of disease in or about the spinal cord, but does not help in making a more detailed diagnosis, and we shall have to depend upon more technical examinations

His lumbar puncture showed block The color and chemistry of the fluid confirm this The lipiodol injection, however, apparently localized the block at the seventh dorsal and not in the upper lumbar region where we rather expected it to be

The x-rays show a destructive process of the seventh and eighth dorsal vertebrae with thickening of the soft tissues on one side The destruction is definite, but covers only a small area, and might well have been missed by a less acute examiner Has he another spinal lesion lower down than the seventh dorsal vertebra? Because of his story of back strain and pain in his hip improving with rest, and because of the sensory disturbance ending

at the level of the second lumbar vertebra, we have had the lumbar region more in mind than the dorsal, which only had one symptom pointing to it. Possibly he has two lesions of a metastatic nature, but the lower lesion is not absolutely necessary. Pressure on the dorsal cord can give leg paralysis without involving the lower trunk or sphincters. This is often seen with tuberculous lesions higher than this. The original hip pain may have been the pain that is sometimes associated with the onset of paralysis due to cord pressure. The ending of the sensory disturbance at the level of the second lumbar vertebra does not fit entirely into the picture, but the definition of sensory levels is not always so accurate as we think it is. Distention and retention of urine simply indicate increasing cord pressure. Operation was done for two purposes—in the hope of relieving cord pressure by laminectomy and for the purpose of biopsy and diagnosis.

We are definitely dealing then with a tumor pressing upon the cord. Is this a metastatic lesion or is it a primary growth? Two metastatic lesions are common at this age—hypernephroma and carcinoma of the prostate. Hypernephroma is an old-age tumor. The spine is the second most frequently involved region, and the presence of metastases may be the first sign of disease. Carcinoma of the prostate commonly involves the spine, and is again a tumor of old age. This patient, however, shows no signs of general metastasis, as is usually the case, and the x-rays are not typical of metastatic carcinoma. They do not show the multiple mottled areas and increased density one would expect to find with a spreading prostatic lesion.

On a percentage basis alone a metastatic tumor, probably hypernephroma, would seem the best bet. However, I think we have no right to argue that way, but must make our deductions entirely on the evidence at hand. Since there is no evidence of any generalized disease, I should prefer to consider a primary tumor to be the cause of his symptoms. The most likely tumors are fibrosarcoma and a very similar tumor of the same group, a neurogenic sarcoma. Both of these tumors erode bones from without inward. Both of them, when occurring in suitable areas, can be shown to cause soft-tissue shadows. The one thing against them is that lesions in the spine are rare. Fibrosarcoma, therefore, is my diagnosis.

PREOPERATIVE DIAGNOSIS

Cord tumor, metastatic?

DR. ROBERTS'S DIAGNOSIS

Fibrosarcoma

ANATOMICAL DIAGNOSIS

Plasma-cell myeloma

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: That this man suffered from a tumor of, or in the neighborhood of, the spinal cord with secondary pressure upon it was fairly obvious when the findings were all in. The question, of course, concerned the type of tumor. Dr. Roberts has placed his bet upon a primary tumor of a spinal nerve root or the dura, whereas the members of the Neurosurgical Service placed theirs upon a metastatic lesion.

The patient was explored by Dr. Jost Michelsen who did a laminectomy of the sixth, seventh and eighth thoracic vertebrae. He found a soft pinkish extradural tumor about 5 mm thick which was compressing the cord from the outside at this level. A frozen section was made by Dr. Charles S. Kubik who was able to give an immediate diagnosis of myeloma. Dr. Michelsen, therefore, removed as much of the tumor as he could but did not attempt any radical surgery. Since the tumor seemed to be entirely extradural and the dura was pulsating normally he did not open it.

The subsequent fixed sections of the tumor confirmed the diagnosis of plasma-cell myeloma. The tumor is made up almost entirely of rather small, round cells with eccentric round nuclei showing the typical cartwheel distribution of the chromatin. As is often the case, many of the cells contain two and three of these nuclei. Following operation the patient was referred to the X-Ray Department for treatment. He received 2400r in eight 300-r doses, but failed to show any improvement in his symptoms. Perhaps Dr. Hampton will say a word in regard to the treatment.

DR. ALBREY O. HAMPTON: The treatments were given through an 8 by 10 cm. field, centered over the eighth dorsal vertebra, and were completed twenty-two days after the operation. The patient has not been observed since that time.

Some cases of plasma-cell myeloma are quite sensitive to radiation, but many others show very little response. This patient is probably in the latter group.

PURE FOOD, DRUG AND COSMETIC BILL

THE House Committee on Interstate and Foreign Commerce has reported favorably a highly undesirable bill for the control of foods, drugs and cosmetics—a bill so bad with regard to method of enforcement that it ought to be entitled “a bill to perpetuate impure foods, drugs and cosmetics.” In it, great ingenuity has been shown in making the legal processes so complex and devious that it will be very difficult to get satisfactory enforcement and almost impossible to obtain quick action on any food, drug or cosmetic that is likely to cause serious disease or even death.

The bill is so impracticable in this feature that the Secretary of Agriculture has written a statement including these vigorous words

If a bill containing this provision were enacted, it would not constitute any material contribution to the public protection that the department cannot now extend under the existing law. In some respects it would afford even less protection than that afforded by the existing law, which is broad and general in its terms and is to some degree applicable and effective in the fields covered by the sections involved in this discussion.

It is the department's considered judgment that it would be better to continue the old law in effect than to enact Senate 5 with this provision.

I am of the opinion that if Section 701 (f) remains in the bill its effect would be to hamstring its administration so as to amount to a practical nullification of the substantial provisions of the bill.

If there is to be exploration into new fields of administrative law, may I urge that it not be in the field of vitally important public health legislation.

The above is quoted from the minority report of the House Committee on Interstate and Foreign Commerce, which was signed by six of its members. (It is pleasing to us that the Honorable Pehr G. Holmes, of Worcester, Massachusetts, the only New England member of this committee, signed this minority report.)

In the minority report the following sentence also appears:

Weighing the advantages and disadvantages for the protection of consumer welfare presented by the terms of this bill, we are unable to escape the conclusion that because of the extraordinary provision for court review of regulations in Section 701 (f), which would postpone indefinitely the consumer protection that can now be afforded in some degree by the present law in much of the field to be covered by these regulations, it would be better to continue the old law in effect than to enact Senate 5 with this provision.

It would be to the advantage of the medical profession and lay public to have this present house bill (Senate 5, Report No. 2139 Union Calendar No. 770) defeated unless these objectionable features are eliminated. The original bill as passed by the Senate on March 9, 1937, is greatly to be preferred to the bill as amended in House committee. If the former cannot be passed, then no bill is greatly to be desired. This would leave legislation on pure foods and drugs in its existing form.

Physicians in New England can help to right a bad situation, if they write promptly to their senators and representatives protesting against the ac-

tion of the committee as outlined above and asking a vote against this bill, unless the section dealing with enforcement be restored to the form contained in Senate 5, as already passed by the Senate

JOSIAH MACY, JR., FOUNDATION

THE Josiah Macy, Jr., Foundation in a recent release reports in a six-year review that from its incorporation until December 31, 1936 it has made three hundred and twenty-four grants totaling \$806,681.75. These grants have been made to thirty-four different universities and twenty-seven other agencies of research in the United States, Belgium, Czechoslovakia, France, Germany, Hungary, Netherlands and U S S R.

Dr Ludwig Kast, president of the Foundation, stresses in his foreword to the report the necessity of preserving the unity of the patient as a psychosomatic entity. In the long run, he believes, the effectiveness of any planning depends upon free and enlightened progress within the medical profession. With the increasing number of processes and reactions to be observed and evaluated and the ever-enlarging number of specialists required to observe and evaluate them, the task of adequate diagnosis and effective health care requires a concern for the patient as an individual personality and the sympathetic insight that the family physician of old was able to offer.

There is, moreover, a great need for the further study of growth, development, maturation and aging, not only as a medical problem but as a social and economic one. The trend is now toward the elimination of the older worker from employment, not only because he cannot sustain the pressure of modern occupations, but also because of the availability of younger men and women for a limited if not, indeed, a rapidly diminishing supply of jobs. This situation, it is believed, will give rise to emotional conditions which must find some release and which, in the older group, will probably be expressed in mental and psychosomatic disorders. This—the health care of the aging individual—is one of the most severely challenging medical, social and economic problems that must be faced in future years.

MASSACHUSETTS MEDICAL SOCIETY

GOLF TOURNAMENT

Due to the fact that there has been so much demand for a Golf Tournament to be held in connection with the annual meetings, the Committee of Arrangements has planned to hold one at the Commonwealth Country Club, 91 Algonquin Road, Newton Center, on Wednesday afternoon, June 1.

One group will consist of those members who hold either state or club handicaps, while a Kickers Tournament has been arranged for those who have no handicaps. A trophy, the Massachusetts Medical Society Golf Challenge Cup, presented by one of the members, will be awarded for the low net score, this must be won three times to obtain permanent possession. Other suitable prizes have been secured for net and gross scores in both divisions.

The details of the tournament itself will be attended to by Mr. John Corcoran, of the Massachusetts Golf Association, thus assuring efficient management.

It is hoped by many of the members that a permanent golf organization may be formed within the Society, and some action will undoubtedly be taken during or following the tournament.

PROPOSED AMENDMENTS TO THE BY-LAWS

Due to a typographical error in the pamphlet announcing proposed amendments to the by-laws, Amendment No. 7 reads "Chapter VII, Section 2." This should have read "Chapter VII, Section 11."

CASE HISTORY No 71 LOW-ATTACHED PLACENTA AT TERM

Mrs. V. D., a twenty-five-year-old multipara, was admitted to the hospital on February 7, 1938, for induction.

The family history was negative and her past history was not important except for a moderately severe attack of pyelitis four weeks after her last confinement in 1936. Catamenia began at thirteen, were regular every twenty-eight days,

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

and lasted four or five days. There had been two previous normal pregnancies. Her last period was April 22, 1937, making her due for delivery on January 29, 1938.

The prenatal course was normal throughout. She was seen at regular intervals of three weeks.

Upon physical examination at admission she was found to be a well-developed and nourished woman. The lungs were clear and resonant, there were no rales. The heart was not enlarged, and there were no murmurs. The blood pressure was normal. The uterus was enlarged to a size consistent with her dates. The urine was free of albumin. As the patient had gone ten days over term, induction was decided upon. When the patient entered the hospital the evening before induction was planned, she was completely symptom free. She was put to bed after a perineal preparation had been done and promptly went to sleep.

At 2 a. m., five hours after admission, the patient called the nurse and said that her membranes had ruptured. On examination the nurse found the bed soiled with bright-red blood, sufficient to make a stain 30 cm. in diameter. The attending obstetrician was called and found the patient in good condition: the blood pressure was 120 systolic, 70 diastolic, the pulse 90, the fetal heart tones regular, at a rate of 140. The fundus was soft, and there was a small amount of bright-red flow from the vagina. A tentative diagnosis of partial separation of the placenta was made. Immediate grouping of the patient's blood was done, and compatible donors were on hand in case of need.

One-quarter grain of morphine was given, and an abdominal binder was firmly placed over the fundus. The patient was then brought to the delivery room where a careful vaginal examination was done under routine precautions. The cervix was two fingers dilated, soft and nearly completely taken up. Careful examination of the lower segment revealed no placenta and confirmed the diagnosis of separation. The vertex was fitting into the inlet with some forebag, and rupture of the membranes to stimulate labor was decided upon. About 200 or 300 cc. of clear amniotic fluid escaped after puncture of the membranes. To take up the slack after the fundus had decreased in size an additional binder was put over the first one to insure its being held securely and to cause pressure on the cervix. Labor began in about half an hour and progressed steadily. The cervix was fully dilated two and a half hours later, and after one hour of ineffectual second-stage labor a low mid forceps was done, the head being posterior on the right and somewhat extended. A healthy male child weighing 8 lb., 8 oz., was delivered. Pituitary solution, 1 cc., was given intramuscularly, the fundus contracted well, and the placenta was ex-

pressed fifteen minutes after the delivery of the child. There was no unusual flow after the third stage, the fundus remaining firm with no need of further stimulation. The placenta was examined carefully and one-third of the outer margin, to a depth of 1 cm., showed evidence of separation. This apparently was the lower margin since it was nearest the point of rupture on the membranes. The postpartum convalescence was uneventful.

Comment. Because a patient has gone ten days over the expected date of delivery is no real reason for induction. The time of induction should always be based upon the condition of the cervix. Had this patient been examined before she went into the hospital, it would have been determined that the cervix was ready for labor. Many cases ten days before the computed day of labor are not ready to have a baby, as is determined by vaginal examination, which fails to show an obliterated and open cervix. The amount of external bleeding would lead one to infer that a partial separation of a low-attached placenta was the cause of the hemorrhage. It is uncommon to have a large amount of external bleeding when a normally situated placenta becomes separated. A vaginal examination is the only way to determine specifically the source of the bleeding. In this case no placenta was felt, and the diagnosis of partial premature separation was made. The treatment was ideal. As it is not stated that the patient was definitely in labor, it is fair to infer that she was not in labor, the vaginal examination which showed the cervix to be dilated two fingers is perfectly compatible with the physiologic change that occurs late in pregnancy. The separation of a low-attached placenta is undoubtedly the commonest cause of bleeding in cases that are close to term.

DEATH

MORROW — CHARLES H. MORROW, M.D., of Gloucester, died May 2. He was in his seventy-eighth year.

A native of Gloucester, he received his medical degree from the University of Pennsylvania School of Medicine in 1885, went to Gloucester shortly afterward and practiced there for fifty-three years. Dr. Morrow was at one time on the staff of the Addison Gilbert Hospital. He was a fellow of the American Medical Association and

of the Massachusetts Medical Society and a member of the Masonic Order

MISCELLANY

PETER BENT BRIGHAM HOSPITAL ANNIVERSARY

On May 5, 6 and 7 a celebration of the twenty fifth anniversary of the opening of the Peter Bent Brigham Hospital for the reception of patients was held at the hospital in conjunction with a reunion of graduates of the professional and nursing services of the hospital

On each of the three days up to 10 30 a. m. various hospital demonstrations ward visits and surgical operations were conducted. After this there was a program of scientific and nursing papers,—more than one hundred in number,—presented by graduates and present members of the hospital professional and nursing staff

On the forenoon of May 7 there was a very large public meeting at which the Rt. Rev. William Lawrence Bishop Emeritus of the Episcopal Diocese of Massachusetts, gave the invocation, His Excellency Charles F. Hurley, Governor of the Commonwealth, gave the Greetings of the State, His Honor Maurice J. Tobin Mayor of Boston, the Greetings of the City of Boston, Dr. Dean Lewis, first surgeon-in-chief pro tempore of the Peter Bent Brigham Hospital, surgeon-in-chief of the Johns Hopkins Hospital, the "Greetings of the Medical Profession," and President James B. Conant, Harvard University the "Greetings of the University." Dr. Henry A. Christian, physician-in-chief of the Peter Bent Brigham Hospital and Hersey Professor of the Theory and Practice of Physic in the Harvard Medical School, made an address entitled "A Hospital Comes to Town. The story of the Peter Bent Brigham Hospital in Boston." Dr. Elliott C. Cutler, surgeon-in-chief of the Peter Bent Brigham Hospital and Moseley Professor of Surgery in the Harvard Medical School, an address entitled "A Surgeon Looks at the Record" and Dr. C. Sidney Burwell, physician at the Peter Bent Brigham Hospital and dean of the Faculty of Medicine of Harvard University, one entitled "The Future of the Hospital." The benediction was pronounced by the Rt. Rev. Francis L. Phelan, chancellor of the Archdiocese of Boston. These exercises were followed by a luncheon on the hospital grounds for all invited guests.

On each afternoon of these three days, tea was served on the hospital lawn. On the evening of May 5 a musical comedy was given at the hospital by the resident professional staff. On the evening of May 7 there was a dinner for four hundred at Vanderbilt Hall, Harvard Medical School, followed by a dance at Longwood Towers, Brookline. At all these events of the celebration the graduates were the guests of the trustees of the Peter Bent Brigham Hospital.

FOURTH ANNUAL RURAL HEALTH CONSERVATION CONTEST

In the Rural Health Conservation Contest, conducted annually by the Chamber of Commerce of the United States in co-operation with the American Public Health Association, the winner for 1937 in the Northeastern Division was recently announced to be Columbia County, New York, and awards of merit go to Barnstable County, Massachusetts Saginaw County, Michigan Southern Berkshire District, Massachusetts Cortland County, New York

Macosta-Osceola Health Unit, Michigan, Richland County, Ohio, and Ottawa County, Michigan.

Some of the points considered by the committee of health experts entrusted with making the awards are (1) the extent to which the water supply is protected, (2) the point at which sanitation has advanced in rural homes, (3) the safety of the milk supply, (4) adequate care of prenatal cases, (5) medical supervision of infants, (6) the availability of well trained nursing service, (7) the degree in which local physicians and dentists aid in the public health program (8) activities to control tuberculosis and syphilis.

9 15 a. m. — Operations.
First Surgical Service, Dr. A. McH. Fraser
Gynecological and Obstetrical Service, Dr. L. E. Phaneuf.
Urological Service, Dr. Roger C. Graves.
10 00 to 11 30 a. m. — Medical ward rounds, Dr. L. F. Curran and associates.
2 00 to 4 45 p. m. — Series of short papers will be read by various members of the several services at the hospital.

WEDNESDAY

9 15 a. m. — Operations.
Second Surgical Service, Dr. W. E. Browne.
Orthopedic Service, Dr. W. R. MacAusland.

10 00 to 11 30 a m — Medical ward rounds, Dr L F Curran and associates.
 2 00 to 4 45 p m — Series of short papers
 8 15 p m Dr Henry A Christian will read a formal paper "Glomerular Dominance in Bright's Disease." This meeting will be held at John Hancock Hall, 90 St. James Avenue, Boston.

Members of the medical profession are cordially invited to attend these exercises. Further information concerning this program can be obtained by calling SOU 2070

WILLIAM E BROWNE, M.D., *Secretary*,
 Advisory Board, Carney Hospital

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The annual meeting of the New England Society of Physical Medicine will be held at the Hotel Kenmore, Boston, on Wednesday evening, May 18, at 8 o'clock.

The council will meet at 6 00, and the informal dinner will be held at 6 30

PROGRAM

Reports of officers and committees.

Election of officers

Address After-Treatment of Poliomyelitis Dr Kristian G Hansson, director of physical therapy, New York Hospital

All members of the medical profession are cordially invited to attend

WILLIAM D McFEE, M.D., *Secretary*

BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

The next meeting of the Boston Society of Psychiatry and Neurology will be held at the Boston Medical Library, on Thursday evening, May 19, at 8 15

PROGRAM

Intracranial Aneurysms Dr C A McDonald and Mr Milton Korb

The Vascular System of the Human Spinal Cord Dr T H Suh

A Method of Measuring Consciousness in Petit Mal Epilepsy Dr R S Schwab

A Case of Mucous Colitis Its psychiatric manifestations Dr M Yorshis

H. HOUSTON MERRITT, M.D., *Secretary*

NEW ENGLAND PATHOLOGICAL SOCIETY

The annual meeting of the New England Pathological Society will be held at the University Club, Thursday, May 19, at 6 30 p m.

Dr Robert A Moore of Cornell University Medical College will speak on Benign Enlargement of the Prostate.

J B HAZARD, M.D., *Secretary*

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, MAY 16

TUESDAY MAY 17

Clinical exercises in observance of the seventy fifth anniversary of the founding of the Carney Hospital

*9 10 a m Boston Dispensary Pathogenic Fungi Dr Jacob Swartz
 9 30 a m Massachusetts General Hospital Thoracic clinic Ether Dome
 *10 a m 12 30 p m Tumor clinic Boston Dispensary
 *12 m South End Medical Club Headquarters of the Boston Tuberculosis Association 554 Columbus Avenue, Boston

WEDNESDAY MAY 18

*Clinical exercises in observance of the seventy fifth anniversary of the founding of the Carney Hospital

8 a m Massachusetts General Hospital Grand rounds Orthopedic Department

*9 10 a m Boston Dispensary Hospital case presentation Dr S J Thannhauser

12 m Boston Society for the Advancement of Gastroenterology Cheever Amphitheater Boston City Hospital

*12 m Clinicopathological conference. Children's Hospital amphitheater

*8 p m New England Society of Physical Medicine. Hotel Kenmore.

THURSDAY MAY 19

8 a m Massachusetts General Hospital Circulatory clinic rounds.

*9 10 a m Boston Dispensary Erythema Nodosum Dr George E. Currier

11 a m Massachusetts General Hospital Medical grand rounds

12 m Massachusetts General Hospital Clinicopathological conference.

6 30 p m New England Pathological Society University Club

8 15 p m Boston Society of Psychiatry and Neurology Boston Medical Library

FRIDAY MAY 20

*9 10 a m Boston Dispensary Hemolytic Streptococcal Infections Factors of Significance in Prognosis and Treatment Dr Chester S Keefer

10 a m Massachusetts General Hospital Fracture rounds

*10 a m 12 30 p m Tumor clinic Boston Dispensary

SATURDAY MAY 21

*9 10 a m Boston Dispensary Hospital case presentation Dr Thannhauser

*10 a m 12 m Staff rounds at the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

*Open to the medical profession

NUMBER 20

SOME NEWER ASPECTS OF THE ALCOHOL PROBLEM

TIMOTHY LEARY, M.D.*

BOSTON

RECENT developments in our scientific knowledge of the effects of alcohol, and the increase in the mortality from alcoholism in this jurisdiction since the repeal of prohibition, make it desirable to review the subject again.

The effects of alcohol in general are referred to in an earlier paper, and need not be considered in detail here.¹ It is now generally accepted that alcohol is a narcotic and not a stimulant. Its apparent stimulant action arises because of its narcotic effect on the cerebral cortex, which serves as an inhibiting brake on the lower cerebral centers. The release of this brake, which is responsible for our conventionalism, our self-consciousness and our inferiority complexes, frees the emotional centers, which then come into control of the activities of the individual. Judgment is warped, muscular co-ordination and technic are lowered.

The term "narcotic" has a sinister connotation to the average mind. It suggests opium, cocaine, chloral and other habit-forming narcotics, but it includes the more benevolent barbiturates and similar agents, to which the world turns, perhaps too constantly, for relief.

Animal experimental evidence of the harmful effects of alcohol is quite limited. Pearl, who in 1914 was a biologist at the University of Maine, had a group of pedigreed chickens on which he studied the toxic effects of alcohol. The exposure was to an atmosphere of alcohol vapor for one hour a day, six days per week. At the end of fifteen months 41 per cent of the control animals were dead, owing largely to an epidemic of roup. None of the alcoholized animals had died. The experiment terminated in 1917, at which time all but one of the alcoholized animals survived. 'Meantime,' said Pearl, "all of their control brothers and sisters had long since died." The control animals, on the other hand, were more fertile than the alcoholic group.

A further study was made of the character of the offspring, thirteen desiderata being considered. Of these useful qualities the alcoholic offspring were superior in nine, the nonalcoholic in two, and in relation to two there were no differences. Chicken fanciers who were called upon to pick the superior animals among the offspring of both groups made selections without knowing the sources of the animals. Ninety per cent of their selections were from the offspring of alcoholic animals.

Pearl² concluded that the lowered fertility of the alcoholic group was due to a selective toxic action on feeble germ cells. Only strongly resistant germ cells produced fertile eggs.

Stockard³ repeated these experiments with guinea pigs. There was a higher mortality in the young among the alcoholic offspring in the early generations and some defective animals in the third generation. In the fourth generation and thereafter, however, there was produced a superior race of guinea pigs, whose mortality was only 64 per cent of the controls. He agreed with Pearl that alcohol apparently had a toxic action upon feeble germ cells, leaving the stronger cells to produce offspring. Stockard concluded:

If we should desire to apply these experimental results to the human alcoholic problem it might be claimed that such elimination of unfit individuals had benefited the races of Europe, since all of the dominant races have a definite alcoholic history.

Apart from the evidence of the toxic influence of alcohol on feeble germ cells, the only effects of ethyl alcohol on experimental animals are as follows: (1) acute intoxication, which may be carried to a fatal issue, (2) a lowering of the resistance to infection in rabbits fed concentrated alcohol by mouth (see below), and (3) an apparent activating influence on the toxic effect of certain poisons.

The dosage of carbon tetrachloride necessary to produce fatal results is markedly lowered in ani-

*Medical examiner, Southern District of Suffolk County, Massachusetts.

imals which have been fed alcohol Mallory⁴ has found that alcohol lowers the dosage of phosphorus necessary for toxic action. Carbon tetrachloride is soluble in water only in traces. Phosphorus (yellow) is practically insoluble. Alcohol is a perfect solvent of carbon tetrachloride, and dissolves phosphorus in amounts adequate to produce toxic action. It is strongly suggested that the solvent action of alcohol is the factor responsible for the increased toxicity of both these agents.

On the other hand, mice may have as their only source of fluid from birth 35 per cent alcohol, and still develop equally with normal controls.⁵

In contrast to the limited effects created in experimental animals, alcohol has been accused of producing in man a great series of pathologic conditions, as follows:

- 1 Acute intoxication—which need not be discussed
- 2 Delirium tremens

There is doubt whether this symptom is of purely alcoholic causation. It does not arise commonly in relation to simple acute alcoholism. Prolonged usage with limitation of diet is the usual history. (See alcoholic neuritis, No 4.) In the chronic alcoholic, delirium tremens may be precipitated by minor injuries or shocks.

3 Alcoholic epilepsy

Alcoholism can precipitate epileptic attacks in old epileptics, and may possibly initiate attacks in individuals who never had attacks. In practically all such cases the subjects are chronic alcoholics. (See psychoses, No 6.)

4 Alcoholic neuritis

In this group, modern thought tends to accuse B₁ avitaminosis as the factor responsible for much if not all the symptom picture. The alcoholic who exhibits these symptoms usually eats little during his debauches or limits his diet to single foods, for example baked beans or spaghetti. The development of avitaminosis may arise from interference with absorption of vitamins in food. The condition may be due to the combined effects of alcohol and avitaminosis, but the cures of neuritis in patients under treatment with vitamin B₁ and given their usual daily intake of large amounts of whisky⁶ do not support these theories.

5 Korsakoff's syndrome

The neuritic elements in this condition apparently owe their origin to B₁ avitaminosis. For discussion of the psychoses see No 6.

6 Psychoses

The evidence signifies that an impaired mental mechanism tends to lead to alcoholic excess. Drunkenness may be merely the herald—the only obvious sign—of incipient mental disorder. Alcohol may be the intensifier, perhaps, but not the cause. Experience in England suggests that intolerance to small amounts of alcohol may be considered a fairly certain sign of impaired mental equilibrium. English inland and agricultural counties show a low incidence of alcoholism and a high insanity rate. In contrast, maritime, manufacturing and mining counties, above all others the most intemperate, have the lowest rates for insanity.

Pearson and Elderton⁷ concluded that the family histories from the Galton Laboratory studies of adult alcoholism “seemed to indicate definitely that *extreme* alcoholism was only consequent on the pre-existing degeneracy of the stock, it was not in itself an antecedent to such defectiveness.”

7 Degeneracy of offspring

Pearson, with Elderton⁸ of the Galton Laboratory, made a study of random samples of normal children and the offspring of alcoholics in Edinburgh and Manchester. The children of alcoholic parents showed a higher mortality, probably due to lack of care. There was a greater fertility, or at any rate a higher birth rate, in the families of alcoholics, and the surviving families were hardly smaller than those of the sober. Children of alcoholic parents were more healthy (perhaps more hardy) than those of abstainers. He concluded “Parental alcoholism is not the source of mental defect in the offspring.” The relationship between parental alcoholism and filial intelligence is so slight that even its sign cannot be determined in the present material. These findings resulted in bitter attacks on the Galton Laboratory, and on Pearson, by the organized “temperance” groups. They quoted from MacNicholl,⁹ Laitinen,¹⁰ Bezola¹¹ and Demme,¹² who had found apparently conclusive evidence in the opposite direction. I recommend highly the study of Pearson's reply,¹³ which is a brilliant piece of medical polemic. He dissected the statistics of the above-mentioned writers and demonstrated that their studies were not made scientifically, that deductions were in many cases absurd on the basis of the material studied and that their work was valueless. Since Pearson's studies we have heard less of the influence of alcoholism in producing degeneracy.

8 Various central nervous lesions

The standard textbooks in neurology are filled with accusations that alcohol is the cause of multiple lesions. Many of the imputations are pal-

pably absurd. For example, thickening and sclerosis of the skull, atrophy of the brain, decrease in the size of the corpus striatum and atrophy of ganglion cells can hardly be ascribed to alcoholism. To one who has seen a brilliant lawyer go through an amazing number of debauches during which the evidence of acute mental upset was complete, and then has observed his return to the courtroom with his cleverness unimpaired, the indictment of alcohol as a cause of definite organic changes in the brain is difficult to accept. Grinker¹⁴ includes *plaques jaunes* as of alcoholic origin. These are of course traumatic in origin. Myelin sheath degeneration suggests B₁ avitaminosis. Optic neuritis is related to methyl alcohol rather than to ethyl alcohol. Proliferation of glia is usually a repair phenomenon which may be due to many causes. To assign its causation to alcohol without supporting data is unjustifiable. In a word, there is little evidence that alcohol per se is the cause of any organic lesions of the central nervous system. Its functional effects may be very great, but the production of permanent lesions is from the modern viewpoint not proved.

9 Subarachnoid hemorrhage

10 Subdural hemorrhage (without contusion or laceration of the brain)

11 Hemorrhage into mammillary bodies

12 Wernicke's polioencephalitis hemorrhagica superior

This group (Nos 9 to 12) of hemorrhagic conditions is often assigned to alcoholism. The evidence with reference to alcoholic association with subarachnoid hemorrhage is weak. Hemorrhages in this condition are commonly arterial, while the hemorrhages in the other conditions are of venous or capillary origin. Recent investigations indicate that in the latter three conditions we are dealing with C avitaminosis usually accompanying alcoholism and arising because of the limited diet. In subdural hemorrhage, which is by far the commonest of these conditions, the usual source of the bleeding is the rupture of a bridging or arachnoid vein, and falls usually precede the hemorrhages. Changes in the vessel wall, such as are met with in scurvy, predispose to rupture of vessels from minor traumatism such as are frequently sustained without hemorrhage by the average individual.

13 Pellagra

The causal relation of this disease to alcoholism was negatived by the finding of widespread pellagra in fanatical Volstead communities in the South. The limited diet of the chronic alcoholic may lead to B₂ (G) avitaminosis, as is true of the limited

diet of poverty, notably the corn-meal diet in the South.

14 Atrophic gastritis and pernicious anemia

Achlorhydria may arise in chronic alcoholics, possibly because of the insult to the gastric mucosa by the ingestion of concentrated alcohol. Atrophy of the gastric mucosa is not found in most cases of chronic alcoholism. Evidence that pernicious anemia occurs more commonly in alcoholics than in the rest of the population is lacking.

15 Increase in the efficiency of poison agents

The solvent action of alcohol is probably accountable for the apparent increased toxicity. (See above.)

16 Laceration of the cardiac orifice with hemorrhage

17 Pancreatic necrosis

Laceration of the cardia may arise from forceful vomiting and may lead to serious or fatal hemorrhage.¹⁵ This condition, fortunately, is not common. That violent vomiting may be a causative factor in relatively rare cases of pancreatic necrosis would appear from the studies of Myers and Keefer.¹⁶ Readers should be warned, however, that pancreatic malacia, as well as gastric malacia, arises rapidly post mortem in alcoholic bodies, and postmortem gas-bacillus activities are common and early.

18 Lowered resistance to infection

Abbott¹⁷ demonstrated that prolonged alcoholic intoxication (50 per cent alcohol per os) caused a marked increase in the susceptibility of rabbits to certain types of infection, and others have confirmed his findings. With Bergey¹⁸ he later demonstrated that in alcoholized rabbits there was a reduction of complement and specific hemolytic receptor. From personal observation I can support these conclusions with reference to increased susceptibility to infection in rabbits fed concentrated alcohol. This is in contrast to the observations of Pearl in chickens exposed to alcohol vapor.

It is recognized that acute lobar pneumonia occurs frequently in alcoholics. Whether exposure or other factors, including avitaminosis, contribute to this apparent susceptibility is not determined. The high mortality in pneumonia in alcoholics is well known, and routine treatment of pneumonia with alcohol apparently adds to the death rate.

19 Cirrhosis of the liver

20 Chronic nephritis

21 Arteriosclerosis

For years these diseases (Nos 19 to 21) were

looked upon as of alcoholic causation Welch¹⁹ said in 1903 "The experimental reproduction in animals of certain of the more characteristic diseases of human beings, attributable to the abuse of alcohol, such as cirrhosis of the liver, chronic Bright's disease and arteriosclerosis, has not been satisfactorily attained"

The work of Mallory¹ demonstrates that ethyl alcohol is not the cause of so-called alcoholic cirrhosis, either the pure type or the pigment type The indications are that alcohol serves as a solvent carrier of the toxic agent, which proved to be copper in the pigment type

The claim that chronic nephritis may be caused by alcohol has been practically dissipated by modern studies of nephritis Indeed some writers believe that alcohol, while an intoxicant, is also a detoxicant, ridding the body of deleterious catabolic poisons (Hultgren²⁰) There is no acceptable evidence that ethyl alcohol produces nephritis, all the supporting data being based upon inference and not on fact However, MacNider,²¹ while unable to produce any evidence of kidney injury in dogs with pure ethyl alcohol, did produce kidney damage with a *fresh* distillate of fermented corn meal and sugar This may be significant in the period since the repeal of prohibition, as so-called whisky even no older than one month has been sold freely in the market

It is perhaps unnecessary to deal with the evidence that has accumulated which indicates that alcohol is not only not the cause of arteriosclerosis but may even have preventive action on its development¹

22 Shortening of life expectation

The studies of Pearl in this relation are well known and need little comment here His studies of random samples of the population led to the conclusion that while the excessive drinker tended to have a shorter life, owing to fatal acute intoxication or accidental causes, the work "gave no evidence that the expectation of life from age 30 on is in any case impaired by the moderate consumption of alcoholic beverages" These findings have been criticized with apparent justice on the ground that the teetotaler was frequently a strenuous, active, driving sort of fellow—an intemperate enthusiast—while the moderate drinker was a person exhibiting self-control, and should have a higher expectation of life than the immoderate zealot

23 Hemorrhagic gastritis

For years so-called "temperance" literature was illustrated by pictures of the horrible hemorrhagic

changes produced in the stomach by alcohol These changes arise post mortem in the form of a malacia, which the gastric mucosa and the pancreas undergo frequently in alcoholics It is not a vital picture

24 Spontaneous combustion

In the *Thousand and One Nights* it is recorded that jinns and afreets together with their victims sometimes suffered death by spontaneous combustion That this form of death should be seriously accepted as a method of termination of life among alcoholics is on the face of it absurd Charles Dickens, however, approved of it as a perfectly reasonable phenomenon *Bleak House*, as with his other books, was published in installments The description of the death of the alcoholic law writer, Krook, nicknamed the Lord Chancellor, from spontaneous combustion led to criticisms of the creditability of this chapter In his preface to the completed work Dickens attempted to answer these criticisms He asserted that about thirty cases of spontaneous combustion were on record He cited the famous case of Countess Cornelia de Bandi Cesenati in 1731 and stated "The appearances beyond rational doubt observed in that case are the appearances observed in Mr Krook's case", and again "I shall not abandon the facts until there shall have been a considerable spontaneous combustion of the testimony on which human occurrences are usually received"

Oliver²² has recently looked into the literature of this subject, which received much attention during the latter part of the eighteenth and the early part of the nineteenth century Women were the usual subjects, fat, asthenic and over sixty years of age Kopp²³ cited eighteen cases, three or four of which he had personally known about He believed that the fire was started by an electric spark such as could be produced by rubbing fur in the cold Dupont²⁴ asserted that some men could send forth light and sparks from their eyes, and concluded that an internal fire producing these phenomena ignited the body

It is presumable that the common use of candles and open fires, the carelessness of the alcoholic with reference to lights and fires, the tendency of alcoholic bodies to undergo rapid postmortem changes, with the evolution of inflammable gas from gas-bacillus activities, and the imagination of observers are accountable for the reported cases At any rate, cases of spontaneous combustion have not been recorded in the modern period

With the exclusion of the organic lesions attributed to alcohol without adequate basis, and the elimination of the bogeys of hemorrhagic gas-

tritis and spontaneous combustion, it becomes evident that the conditions due to alcoholism in the human being correspond to those which can be produced in experimental animals, namely, acute intoxication, lowering of resistance to infection (concentrated alcohol by mouth) and reinforcement of the action of certain poisons by favoring solution

Now that we are on a firm basis with reference to what alcohol directly does in the human body, we may consider more honestly the injury which it is proved to cause in humankind. It should be kept in mind that alcohol is responsible for estab-

injuries (other than automobile) directly resulting from alcoholism. The years 1916 and 1917 were the "silk shirt" period, when wages were high and employment in producing war supplies for the Allies and ourselves was at its height. We had entered the War in 1917. In 1918 and 1919 patriotic demands for retrenchment and temperance led to a marked lowering of the death rate. A man who became drunk publicly was ostracized, and a drinker could not hold a job. We became one of the most temperate people in the world. Then prohibition was established. The low death rate in 1920 was due to the nonavailability of supplies of liquor. The demand was met in 1921 and 1922 by home-brewing and the use of alcoholic extracts (Jamaica ginger, vanilla, bay rum, and so forth). By 1923 an efficient, if illegal, supply of bootleg alcoholic fluids was available, and this continued during the prohibition era. It was as easy to smuggle a bottle of whisky or concentrated ethyl alcohol as it was to smuggle a bottle of beer,

Chart 1

lishing the conditions which favor the production of avitaminoses, it may precipitate the development of psychoses, it is the carrier of the agents producing cirrhosis, it alone or with avitaminosis is accountable for the vomiting which may cause lacerations of the cardia and pancreatic necrosis.

The social effects upon the victims of alcoholism and their families we need not review. However, the tremendous local increase in alcoholism since the repeal of prohibition and the evidence that this increase is largely among the poor present a problem that must be met. This evidence appears in the accompanying charts.

Chart 1† gives the record of annual deaths from alcoholism at the Boston City Hospital, and illustrates the abnormally high death rate in 1934 and 1935, since the repeal of prohibition. (Compare Chart 4.)

Chart 2 shows the annual deaths from conditions related to alcoholism in the Southern Medical Examiner District of Suffolk County, it illustrates the increased number of deaths arising in my personal service as medical examiner*. In the period up to 1915 there was a quite standard low death rate from conditions related to alcohol—including pure alcoholism, alcoholic pneumonias, and

DEATHS RELATED TO ALCOHOLISM

MEDICAL EXAMINER SERVICE — SUFFOLK COUNTY—SOUTH P.

Chart 2

and the profits were greater with concentrated liquors. Prohibition developed in the American people a taste for hard liquor and a disrespect for law.

With the repeal of prohibition there was an increase in local deaths in contrast to a lowering of the mortality from alcoholism in other parts of the country. From police reports and the liquor bottles found on alcoholic patients it became evi-

†Reprinted through the courtesy of Moore M. and Gray M. G. The problem of alcoholism at the Boston City Hospital. New Eng J Med 17:351-358 1937.

*Because of illness in 1936 I saw fewer cases. The percentage of cases of alcoholism actually seen applied to the average number of cases seen per annum would indicate a mortality of 315 for 1936.

dent that this increase in mortality was due largely to the drinking of grain alcohol, though some of the makeshift whiskies sold since the repeal of prohibition played an important part. Massachusetts law permits the sale of 95 per cent alcohol (190 proof) over the counter in drugstores without a prescription. Properly diluted at the beginning of a debauch, this was frequently used in greater strength as drunkenness came on. The presence in the blood or brain of 0.5 per cent of alcohol ensures a fatal outcome.

Chart 3* gives the record of deaths from alcoholism in New York City and shows a drop in the

Chart 3

mortality since prohibition. (The low death rate in 1932 was probably due to the widespread publicity given to the deaths resulting from drinking methyl [wood] alcohol, which occurred during 1930 and 1931.)

These charts indicate a marked *increase* in the mortality from alcoholism at the Boston City Hospital since the repeal of prohibition (Chart 1), a marked *increase* in the mortality from conditions related to alcoholism in the Southern Medical Examiner District of Suffolk County since the repeal of prohibition (Chart 2), and a *decrease* in the deaths from alcoholism in New York City since the repeal of prohibition (Chart 3). Ethyl alcohol can be purchased in New York State only on a physician's prescription.

The conclusions are obvious. The drugstore sale of ethyl alcohol over the counter in Massachusetts should be stopped.

A second series of charts illustrates the contrast between admissions for alcoholism to a free public clinic and the admissions to a pay clinic.

Chart 4 presents the Boston City Hospital's record of admissions for alcoholism. It illustrates the continued high curve since the repeal of prohibition, necessarily limited since repeal by the crowded condition of the institution.

Chart 5 shows admissions to the Washingtonian Home, an institution for inebriates with a curve contrasting with that of Chart 4. In 1928 a rule was put into effect that inmates should pay twenty dollars per week in advance. In 1929 and since

that time the home has been closed one month each year. That month was August, the month in which there were fewest admissions. I have divided the eleven-month record of admissions by 11 and multiplied the quotient by 12, placing dots

ADMISSIONS FOR ALCOHOLISM BOSTON CITY HOSPITAL.

Chart 4

above the curve of actual admissions. It will be noted that granting full allowance for the twelve-month period there is no essential change in the curve.

These charts demonstrate a *high* incidence of admissions for alcoholism to the Boston City Hos-

ADMISSIONS FOR ALCOHOLISM WASHINGTONIAN HOME.

Chart 5

pital since the repeal of prohibition (Chart 4), and a *low* incidence of admissions to the Washingtonian Home under requirements of payment for service in advance (Chart 5).

These contrasting records indicate that the increase in alcoholic admissions to the Boston City Hospital is due to alcoholism among the poor. There is supporting evidence that cash advanced by the City of Boston under welfare provisions is used to buy the ethyl alcohol responsible for

*Reproduced through the courtesy of Dr. Thomas A. Gonzales, chief medical examiner, New York City.

much of this increase in drunkenness. Again the conclusions are obvious. That money advanced by the Welfare Department of the City of Boston should be the means of debauching and killing among the poor is monstrous.

It has been assumed by superior persons that the deaths in this series occurred only among derelicts—human outcasts, for whom nobody cared. Out of 310 deaths in 1937 the bodies of all but 18 were buried by relatives, their estates or their friends. The depression has been an important factor in undermining character, and alcohol as an escape mechanism has been too readily available for all groups, including often the former wage earner of a family.

ALCOHOLISM A PUBLIC HEALTH PROBLEM

In colonial and provincial times, and in the post-revolutionary period as well, the drinking of alcoholic beverages was common and proper. Cider of varying degrees of hardness was supplied to students at Harvard as a matter of course. Rum, for whose manufacture New England was famous, was used freely.

The so-called "temperance" movement began in the decade 1830-1840. Pews in the churches were not filled, and a new slogan was needed to awaken the apathetic public. Bradford has said "The puritan cultivates a sense of sin as the artist cultivates a sense of beauty." And so there was born a new sin—not drunkenness, but drinking. The "temperance" movement became a total abstinence crusade.

It was in this period that De Tocqueville wrote (in *Democracy in America*) "If an American were condemned to confine his activity to his own affairs he would be robbed of one half of his existence, he would feel an immense void in the life which he is accustomed to lead and his wretchedness would be unbearable."

Alcohol the *spirit* by its narcotic action on the cortical brake leaves the drunkard dominated by his emotions. Alcohol the *word* seems to have the same effect on the cortical brain cells of the extreme wets and dries, who cease to be rational beings in discussing the subject, and are swayed solely by their emotions.

Irving Cobb in his series of *America Guyled Books* takes as the motto of Kansas "Am I my brother's keeper?" You bet your sweet life I am." And so every American whose emotions are stirred by the evil effects of alcohol, seems to believe him or herself divinely constituted, ipso facto, to be an expert on alcoholism. Carrie Nation has many sisters who only lack her daring.

They do things differently abroad. When England entered the World War she decided wisely to investigate all agencies which might interfere with the efficiency of the nation. She therefore ap-

pointed a scientific commission to study the subject of alcohol. That commission was made up of a pharmacologist (Cushney), a physiologist (Sherrington), a pathologist (Mott), a biological chemist (Dale), two alienists (Sullivan and McDougall) and a statistician (Greenwood), with Lord D'Abernon as chairman. The findings of this commission, practically applied, resulted in a marked increase in temperance in Great Britain.

Similarly in Denmark when the blockade during the war limited supplies, prohibition was tried for one month and abandoned. Dr. Hindhede then established a system of restriction which has practically eliminated delirium tremens as a problem in the hospitals of Copenhagen. Sweden actually voted for prohibition, but common sense prevented its being put into practice. Under the system of restriction instituted by Dr. Bratt, and bearing his name, Sweden has been converted from one of the most alcoholic nations in the world into a temperate people.

It is too much to hope that with our heterogeneous population we can equal in a few years the efficient results obtained in Great Britain and Scandinavia, with their homogeneous populations. It is my opinion, however, that until we approach the study of alcoholism from the standpoint of a public-health problem we shall fail in its solution. Sane legislation based upon scientific knowledge offers the greatest hope for successful control of chronic alcoholism, which is, in the last analysis, a disease.

NEPHRITIC TOXEMIAS OF LATE PREGNANCY

A Clinical Study

LOUIS E PHANEUF, MD,* AND MAURICE O BELSON, MD†

BOSTON

THE Carney Hospital, established seventy-five years ago, maintained a separate gynecological service during the first fifty-seven years of its existence. In 1919 an obstetrical service was established and combined with the gynecological. The combined service consists of twenty-eight gynecological and twenty-one obstetrical beds. By moving women who are out of bed and almost ready to go home to one of the small gynecological wards, we are able to care for twenty-five obstetrical patients when conditions so demand. This department has derived its clientele from three sources: the hospital's prenatal clinic, patients referred by physicians, largely those practicing near by the institution, and private patients. The largest group comes from the prenatal clinic.

From 1919 to 1936 inclusive there were 6909 deliveries. Of these there were 88 cases with nephritic toxemia of late pregnancy, an incidence of 1.28, or 1.3 per cent. All patients registering at the prenatal clinic are advised to report for examination every two weeks, and oftener if any complications arise. With such a small service only a limited number of patients can be treated, but the great advantage is that the service can be closely supervised. Our toxemias came from the three sources already mentioned, the more severe ones and those admitted in a moribund condition being referred to the hospital by physicians who usually had been called for the emergency and had not seen the patient before. Since the financial depression of 1929 many of the patients who formerly came to us have been referred to hospitals where no charge was made for ward beds, so that during the last seven years of our study the largest number of admissions came from our own prenatal clinic. During the seventeen years covered, there were only 6 cases of toxemia of the convulsive type or true eclampsia (4 antepartum cases and 2 postpartum), an incidence of 1/1151, or 0.1 per cent. (Stander's¹ collected cases give an incidence of 1/254, or 0.4 per cent.) A number of interns who have spent a year on the service have not seen a woman in convulsions. This has been due in large measure to prenatal care,

which has become well standardized in all clinics. The foregoing is in contrast to the experience of one of us (L. E. P.) who, while serving as indoor house surgeon at the New York Lying-In Hospital in 1914, saw patients with eclampsia admitted almost daily.

Eclampsia has been called the disease of theories. Despite the tremendous amount of research which has gone on and is still going on, the etiology remains obscure. The management of nephritic toxemias has undergone a marked change since the beginning of the present century. It was felt then by many accoucheurs that a woman suffering from severe toxemia and even having convulsions should be delivered at once. This belief was responsible for *accouchement forcé* with resulting deep lacerations of the cervix, sometimes rupture of the uterus, and septic phenomena frequently followed this forceful and brutal method of delivery. At this period a certain school of obstetricians favored immediate delivery by cesarean section—usually performed under full ether anesthesia—for the gravida admitted in convulsions and without labor, this anesthetic added a severe load on already badly damaged kidneys, and the operation superimposed marked shock on a very sick patient. During this same period of time chloroform, known to have extremely toxic effects on the liver, was given by inhalation to arrest the convulsions. The work of Stroganoff² and others in the medical or conservative treatment of eclampsia showed such improved results over the radical methods of immediate delivery by operative procedures that nowadays conservatism is resorted to in all well-conducted clinics, cesarean section playing but a small role in the management of this disorder.

The treatment, as applied now, is directed to the toxemia, and the pregnancy is disregarded for the time being, delivery being accomplished by one means or another only after the patient has improved from her toxic state or when the convulsions have subsided. Labor is usually induced by the simplest means at our command, namely the administration of castor oil, quinine in small doses and the rupture of the membranes. In the management of this malady cesarean section is reserved for primigravidas with long, rigid cervixes who fail to respond to medical treatment, in order to de-

Read at the annual meeting of the New England Obstetrical and Gynecological Society, Boston, December 1, 1937.

Professor of gynecology, Tufts College Medical School.

Attending physician of gynecology, Tufts College Medical School.

liver them before the onset of convulsions, and for those who have a definite indication for the operation on the basis of pelvic contraction and disproportion. Statistics have shown that the highest maternal mortality occurs during convulsions, the cause of death being ascribed in large measure to cerebral hemorrhage. Admittedly there are still a small number of women who develop toxemia and even eclampsia despite the best prenatal care we are able to give them. However, most of the severe cases we encounter occur in women who have had no prenatal care. Our own experience has been that it is sometimes extremely difficult to make patients who live almost next door to the clinic report for their bimonthly examinations.

We considered patients as toxemic when one or more of the following findings were present: elevated blood pressure, heavy trace of albumin, urinary casts, pitting edema of extremities or face, or both, associated with subjective symptoms of persistent headache, blurring of vision, dizziness or epigastralgia.

Seasonal Incidence The incidence of the cases according to season was as follows: spring, 23 per cent, summer, 25 per cent, autumn, 23 per cent, winter, 30 per cent. The largest number of cases occurred in October and December, each month having 15 per cent. The smallest incidence was in September, 2 per cent.

Age Tabulating the patients according to ages in five-year groups, we found 11 per cent from twenty-one to twenty-five years, inclusive, 30 per cent from twenty-six to thirty, 31 per cent from thirty-one to thirty-five, 25 per cent from thirty-six to forty, and 3 per cent from forty-one to forty-five. Combining these into ten-year groups gave an incidence of 41 per cent for the third decade, as compared with 56 per cent for the fourth decade, making a 15 per cent increase in incidence in the older group.

Parity Fifty per cent (44 patients) were primigravidas.

Duration of Pregnancy When Toxemia Was Noticed The percentage of the toxemic patients increased markedly as term was approached: from 11 per cent at twenty-two to twenty-six weeks to 20 per cent at twenty-seven to thirty-one weeks, and 68 per cent at thirty-two to thirty-six weeks.

Prenatal Care These cases were analyzed as to the type of prenatal care received, and divided into three groups, as follows: adequate care, inadequate care, no prenatal care. The patients who registered before the fifth month of pregnancy and who were regular in attendance were considered as having had adequate care. Those who registered

late in pregnancy or those who did not make regular prenatal visits were placed in the inadequate-care group. Those who had seen no physician, who were beyond the fifth month of pregnancy and who were toxemic or moribund when admitted were considered as having had no prenatal care.

Analysis of the cases showed that 36 per cent had adequate care, 55 per cent inadequate care and 9 per cent no care. Almost two thirds (64 per cent) of these toxemic patients had either inadequate or no prenatal care. This is a rather high percentage in this day and age, when we are constantly preaching about prenatal care to medical students, physicians and the laity. But we must take into consideration the fact that these cases go back to 1919, when prenatal care was not expounded to the laity so strenuously as it is today.

Onset of Labor Labor began spontaneously in less than one third (30 per cent) of the patients. It was induced medically (castor oil and quinine) in 1 per cent, and by the artificial rupture of the membranes either alone or with an additional procedure, such as the use of a Voorhees bag, bougie or gauze pack, in 42 per cent. The low transverse cervical cesarean section was employed in 20 per cent, Hirst cesarean in 1 per cent (1 case), and vaginal cesarean section in 6 per cent.

In no case was a cesarean section performed during the active stage of eclampsia or during convulsions.

In evaluating these statistics we must take into consideration the fact that many of these abdominal cesarean sections and all the vaginal ones were done at a period when the rapid emptying of the uterus as a means of treatment was still in vogue with some obstetricians.

Method of Delivery A little over one third (37 per cent) of the patients delivered spontaneously. The remaining women were delivered as follows: by forceps, 13 per cent, by internal podalic version, 14 per cent, by breech extraction, 6 per cent, by low transverse cervical cesarean section, 20 per cent, by Hirst cesarean, 1 per cent, by vaginal cesarean, 6 per cent, and by postmortem cesarean, 4 per cent.

Fifty per cent of the abdominal cesarean sections were performed under local anesthesia.

Infant Mortality A little more than one half (55 per cent) of the babies were born alive, 10 per cent died of prematurity within three days, 1 per cent (1 case) died of hemorrhagic disease of the newborn.

Slightly under one half of the stillborn were macerated fetuses. Included in the stillborn were 3 postmortem cesarean babies, at twenty-two, thirty-three and thirty-six weeks of pregnancy, respectively. The chance for a living baby in a toxemic

patient, as shown by this group of cases, is a little better than 1 2

Maternal Mortality Five deaths occurred, an uncorrected maternal mortality of 6 per cent. All these women had had inadequate prenatal care. 4 died undelivered, and 2 were admitted in moribund condition and died within twenty-four hours.

Case 1 A primigravida, aged 35, was 7½ months pregnant. She had a blood pressure of 250/120. The urine examination revealed 3+ albumin, with hyaline and granular casts and blood cells in the sediment. She had had four antepartum convulsions. Her prenatal care was inadequate. The diagnosis was eclampsia, acute nephritis and hypertension. She died undelivered and a postmortem cesarean section was performed. The fetus was stillborn.

Case 2 A primigravida, aged 40, was at term. She had had inadequate prenatal care. Her blood pressure was 200/120. Examination of the urine revealed 3+ albumin. The diagnosis was eclampsia. A first cesarean section was performed, a stillborn fetus being obtained.

Case 3 A quintgravida, aged 40, was 5 months pregnant, on admission she had a blood pressure of 266/104 and marked edema of the lower extremities. Examination of the urine revealed 2+ albumin, and hyaline and granular casts in the sediment. Her prenatal care was inadequate. In addition to toxemia of pregnancy she had hypertension, renal and pulmonary tuberculosis and aortic regurgitation. She died undelivered, and a macerated fetus was obtained when a postmortem cesarean section was performed.

Case 4 An octogravida, aged 38, was 6 months pregnant. She had a blood pressure on admission of 250/130. Examination of the urine revealed 3+ albumin, and hyaline and granular casts. Her prenatal care was inadequate. She had had a cerebral hemorrhage, and when admitted to the hospital was in a moribund condition and died within 24 hours.

Case 5 A primigravida, aged 36, was 8 months pregnant. She was admitted in a moribund condition. Her blood pressure was 182/120. Urine examination revealed 2+ albumin and hyaline casts. She had had inadequate prenatal care, and died within 24 hours. A postmortem cesarean section was performed, and a stillborn fetus was obtained.

Previous History of Toxemia Fifteen patients, or 17 per cent of our series, had had toxemia of pregnancy previously, 2 of them twice. When we remove from this group the primigravidas, who constituted 50 per cent of the entire number, and who ipso facto could not have had a previous toxemia, the percentage rises to 34.

In these multigravidas we were able to determine the condition of the kidneys in the intervening period between the previous toxemic condition and the present illness, and found that chronic nephritis was the underlying cause of these repeated toxemias. Chronic nephritis with hypertension accounted for 9 per cent of the entire group, or 18 per cent of the multigravidas, and chronic nephritis alone for 8 and 16 per cent, respectively.

Accidents of Labor There were 2 cases in which accidents of labor occurred.

Case 6 A primigravida, aged 24, was 6 months pregnant. She had had inadequate prenatal care. On admission examination revealed a premature separation of the placenta associated with hydramnios. Her blood pressure was 172/108. She had 3+ albumin in her urine. The membranes were ruptured artificially and she was delivered normally of a stillborn fetus. She had an uneventful recovery.

Case 7 A quintgravida, aged 39, was at term. She had had adequate prenatal care. On admission a diagnosis of marginal placenta previa was made. Her blood pressure was 185/100. Urine examination showed a trace of albumin. She was delivered by version and extraction. The baby died in 2 days and the mother made an uneventful recovery.

Treatment We did not adhere rigidly to any one regime. Our treatment consisted of a combination of sedation, elimination and diet. Sedation was obtained by the moderate use of morphine, bromides, chloral hydrate and the barbiturates.

For elimination, colonic irrigations and gastric lavage were used. In addition magnesium sulfate was given by mouth, or 20 cc of a 10 per cent solution intravenously, or 20 cc of a 25 per cent solution intramuscularly every hour for five doses, and repeated as necessary. We also used hypertonic glucose solution intravenously. A low-protein and low-salt diet was also utilized.

If the patient was in labor she was delivered as soon as possible, normally, by forceps or by version and extraction. Spontaneous delivery was preferred if she was having active labor and was progressing rapidly, but we did not allow a long second stage of labor, terminating such cases by forceps or version and extraction.

In multiparas, if the patient was not in labor it was induced by the artificial rupture of the membranes, either alone or in combination with the insertion of a Voorhees bag, a bougie or a gauze pack. The primigravidas who did not improve under the medical regime, and in whom we feared the onset of convulsions, the elderly women who had long rigid cervixes and the younger group who had some pelvic contraction or disproportion between the pelvis and the fetal head, were delivered by the low transverse cervical cesarean section, preferably under 1 per cent novocaine local anesthesia.

CONCLUSIONS

Careful supervision of pregnant women (prenatal care) has greatly improved results in nephritic toxemia of pregnancy.

An occasional patient develops eclampsia even

though she has had what is considered adequate prenatal care

Since the early part of this century the management of the toxemias of pregnancy has changed from radical to conservative

The treatment should be directed to the toxemia, and the pregnancy should be disregarded for the time being

Delivery through the pelvis by the simplest means possible has shown far better results than were obtained by radical abdominal delivery

Accouchement forcé is a relic of the past, and should have no place in the management of the toxemic patient

Cesarean section is but rarely indicated, and should be employed only in the delivery of a primigravida with a long rigid cervix who fails to improve under medical regime, in order to termi-

nate pregnancy before the onset of convulsions. The operation has to be considered in the presence of a contracted or malformed pelvis

Vaginal cesarean section, devised for the immediate delivery of a toxic patient, has been almost entirely discarded

In seventeen years at the Carney Hospital there were 6909 deliveries with 88 cases of late nephritic toxemia of pregnancy, an incidence of 1.78, or 1.3 per cent

Six women in the series had convulsions or eclampsia (4 antepartum and 2 postpartum), an incidence of 1.1151 or 0.1 per cent

CASE 24201

PRESENTATION OF CASE

First admission A twenty-nine-year-old, white, American woman entered the hospital with the complaint of skin eruptions of two weeks' duration

About ten months before entry she began to have intermittent cough productive of moderate amounts of white sputum. She had lost about 10 lb. in weight during the two months previous to that time, and she noticed that she was gradually beginning to tire easily. About six months before entry she began to have pain in both knees and in her left hip. They felt hot and slightly tender and appeared to be swollen. Application of local heat gave complete relief after a few days. Six weeks before entry the joint pains returned with greater severity, and she also had soreness in the calves of both legs. The pain was not sufficiently severe to interfere with her work. Two weeks before entry small, reddish-purple, non-tender, maculopapular eruptions appeared on the exterior surfaces of her arms and thighs and spread to her face. Four days later ecchymotic areas about the size of a fifty-cent piece appeared on her arms and on the flexor surfaces of her legs, which gradually increased in size. One week before entry she had a temperature of 100°F, without chills, and for the two days before entry she had repeated nosebleeds. She had no hematemesis, hemoptysis, hematuria or melena, but her last menstrual flow three weeks before entry had been very profuse, with clots. During the two weeks before entry she lost about 5 lb. in weight and had had moderate malaise.

About a month after she was married, which was twelve years before entry, she had had attacks of severe dysuria and frequency which subsided after a period of treatment with douches. About one and a half years later while at a sanatorium for a "nervous breakdown" it was discovered that she had syphilis. For the year after that she had weekly arm and hip injections, and for the four months before entry she had again been given weekly hip injections. She stated that she had never been in very good health and that she had always had vague spells of difficulty in breathing.

She had no other cardiorespiratory symptoms or any history of previous blood dyscrasias or skin diseases. Her family history was essentially negative.

Physical examination revealed a well-developed and nourished woman in no apparent discomfort. There was slight pallor of the mucous membranes. On the face there were many papular urticaria like lesions with denuded surfaces, and a few similar lesions on the chest. On the left wrist and lower legs there were several ecchymotic areas, and there were petechiae on the lower legs, arms and buccal mucosa. There was a systolic apical heart murmur, and the blood pressure was 120 systolic, 86 diastolic. The abdominal and pelvic examinations were negative.

The temperature was 99°F, the pulse 85. The respirations were 20.

The urine had a specific gravity of 1.016 and was negative. The blood showed a red-cell count of 3,260,000 with 60 per cent hemoglobin, and a white-cell count of 4000 with 48 per cent polymorphonuclears, 43 per cent lymphocytes, 8 per cent monocytes and 1 per cent eosinophils. The platelets were greatly diminished. There were 12 per cent reticulocytes. The guaiac test on the stool was negative. The blood Hinton test was twice positive, and the blood Wassermann negative. The van den Bergh on the blood serum was normal, indirect. The bleeding time was 2 minutes, the clotting time 12 minutes. A lumbar puncture was entirely negative. The spinal-fluid Wassermann was negative.

An electrocardiogram showed a tendency to slight right-axis deviation, upright T₁, low T₂, inverted T₃ and T₄ and short Q₄. An x-ray of the chest showed no evidence of disease in the heart or lungs.

A tourniquet test done on the third day was positive. On the eleventh day the bleeding time from the ear was 15½ minutes and from the finger 16½ minutes. The clotting time was about 13 minutes and there was no clot retraction after sixteen hours. A sternal biopsy done on the fourteenth day showed hyperplasia of the marrow. There was increased cellularity, particularly evident in the granulocytic series. Megakaryocytes were also increased, the older forms being predominant. After the biopsy the patient vomited about an ounce of material which appeared to be changed blood. She had begun her menstrual period on the eighth hospital day and continued to flow quite profusely for two weeks. On the fifteenth day the red-cell count was 2,460,000 with 55 per cent hemoglobin. On that day her temperature rose to 101.5°F. Two days later she was given a transfusion of 550 cc of blood, and following that her temperature rose to

103°F It gradually fell to normal, but after another transfusion three days later, on the twenty-first day, she had chills and her temperature rose to 103.4°F Her red-cell count that day was 1,850,000 with 40 per cent hemoglobin, and the guaiac test on the stool was 4+ The stool was tarry in appearance In the next five days she was given three more transfusions totaling 1550 cc, at the end of which time her red-cell count was 1,970,000 with 45 per cent hemoglobin Her bleeding time on the twenty-fourth day was 20½ minutes, and a catheter urine specimen on the twenty-sixth day was grossly bloody The patient had refused to have a splenectomy but finally consented to the operation, which was done on the thirty-fourth day Preoperative and postoperative transfusions were given The bleeding time immediately after the operation was 9 minutes, and the following day it was 3½ minutes The clotting time was 4 minutes On the second postoperative day all bleeding from the gastrointestinal and genitourinary tracts had stopped Two days later the bleeding and clotting times were both 3 minutes, and there was slight clot retraction at the end of twenty hours The red-cell count was 2,450,000 with 46 per cent hemoglobin, and the white-cell count was 11,000 with 86 per cent polymorphonuclears, 10 per cent lymphocytes, 3 per cent monocytes and 1 per cent eosinophils The serum protein was 4 gm per cent On the eighth postoperative day the bleeding and clotting times were 3 and 4 minutes respectively, and clot retraction was complete in two hours She was discharged on the fifty-fifth day Her red-cell count at that time was 3,250,000 with 65 per cent hemoglobin, and the white-cell count was 8500 The platelets were still apparently reduced in number

Final admission (eleven weeks later) After discharge she went to a convalescent hospital, where she remained for two weeks She was very weak and still had a blotchy macular eruption on her face, arms and chest, which was crusted and itched a good deal She also had daily nosebleeds which were scant in amount, not nearly so profuse as before her first entry About six weeks before re-entry she again began to have joint pains which were much more severe than any she had had before and were her chief complaint at the time of re-entry One joint after another in her legs became swollen and painful and remained so for about a week when the process would gradually subside, only to recur later Her knees were most constantly affected She never noticed redness or discoloration of the joints The tendons of the middle two fingers of each hand periodically contracted so that she was unable to straighten the fingers and remained in that condition for several days The

skin lesions had gradually become more advanced, and the patient felt that during the month before re-entry she had lost a good deal of strength and weight After the splenectomy her menstrual periods had been regular but quite scanty, lasting only three days During her last period before re-entry she had noticed some small black and blue spots on her buttocks, these promptly disappeared During the entire period between entries she had taken daily doses of codeine and aspirin She had had no hematemesis, melena, hematuria, hemoptysis, nausea, vomiting, diarrhea or abdominal or chest pain She had had no pains in her muscles and no neurologic symptoms

Physical examination showed a fairly well-developed and nourished woman, who did not appear to be acutely ill There was a blotchy macular and papular skin eruption on the face, neck, anterior midchest and arms, with a shiny atrophic surface and some scaling and induration Many of the lesions had been excoriated There were similar lesions on the labia majora, and there were a few small petechiae on the inner aspects of the thighs There was slight generalized enlargement of the lymph nodes The heart, lungs and abdomen were negative, except for the splenectomy scar The uterus was enlarged to about the size of an orange and was freely movable The blood pressure was 115 systolic, 80 diastolic

The temperature was 99°F., the pulse 90 The respirations were 20

The urine had a specific gravity of 1.018, and contained a very slight trace of albumin The sediment contained many white cells and occasional hyaline and granular casts A urine concentration test gave a maximum specific gravity of 1.016 The blood showed a red-cell count of 3,600,000 with 65 per cent hemoglobin, and a white-cell count of 9500 with 78 per cent polymorphonuclears, 21 per cent lymphocytes and 1 per cent monocytes The guaiac test on the stool was negative The bleeding time was 1½ minutes, the clotting time 14½ minutes, and the tourniquet test negative The sedimentation rate was 1.99 mm per minute A blood culture gave no growth

An x-ray of the chest on the fifth day showed definite change from the last examination four months previously The transverse diameter of the heart was about 3 cm larger, and there was diffuse dilatation There was a little passive congestion in the lung fields X-ray photographs of the hands showed tufting of the terminal phalanges suggesting pulmonary osteoarthropathy X-rays of the sinuses were negative

A urine specimen on the ninth day contained a trace of albumin, and all subsequent urine speci-

CASE 24201

PRESENTATION OF CASE

First admission A twenty-nine-year-old, white, American woman entered the hospital with the complaint of skin eruptions of two weeks' duration

About ten months before entry she began to have intermittent cough productive of moderate amounts of white sputum. She had lost about 10 lb in weight during the two months previous to that time, and she noticed that she was gradually beginning to tire easily. About six months before entry she began to have pain in both knees and in her left hip. They felt hot and slightly tender and appeared to be swollen. Application of local heat gave complete relief after a few days. Six weeks before entry the joint pains returned with greater severity, and she also had soreness in the calves of both legs. The pain was not sufficiently severe to interfere with her work. Two weeks before entry small, reddish-purple, non-tender, maculopapular eruptions appeared on the exterior surfaces of her arms and thighs and spread to her face. Four days later ecchymotic areas about the size of a fifty-cent piece appeared on her arms and on the flexor surfaces of her legs, which gradually increased in size. One week before entry she had a temperature of 100°F, without chills, and for the two days before entry she had repeated nosebleeds. She had no hematemesis, hemoptysis, hematuria or melena, but her last menstrual flow three weeks before entry had been very profuse, with clots. During the two weeks before entry she lost about 5 lb in weight and had had moderate malaise.

About a month after she was married, which was twelve years before entry, she had had attacks of severe dysuria and frequency which subsided after a period of treatment with douches. About one and a half years later while at a sanatorium for a "nervous breakdown" it was discovered that she had syphilis. For the year after that she had weekly arm and hip injections, and for the four months before entry she had again been given weekly hip injections. She stated that she had never been in very good health and that she had always had vague spells of difficulty in breathing.

She had no other cardiorespiratory symptoms or any history of previous blood dyscrasias or skin diseases. Her family history was essentially negative.

Physical examination revealed a well-developed and nourished woman in no apparent discomfort. There was slight pallor of the mucous membranes. On the face there were many papular urticaria like lesions with denuded surfaces, and a few similar lesions on the chest. On the left wrist and lower legs there were several ecchymotic areas, and there were petechiae on the lower legs, arms and buccal mucosa. There was a systolic apical heart murmur, and the blood pressure was 120 systolic, 86 diastolic. The abdominal and pelvic examinations were negative.

The temperature was 99°F, the pulse 85. The respirations were 20.

The urine had a specific gravity of 1.016 and was negative. The blood showed a red-cell count of 3,260,000 with 60 per cent hemoglobin, and a white-cell count of 4000 with 48 per cent polymorphonuclears, 43 per cent lymphocytes, 8 per cent monocytes and 1 per cent eosinophils. The platelets were greatly diminished. There were 12 per cent reticulocytes. The guaiac test on the stool was negative. The blood Hinton test was twice positive, and the blood Wassermann negative. The van den Bergh on the blood serum was normal, indirect. The bleeding time was 2 minutes, the clotting time 12 minutes. A lumbar puncture was entirely negative. The spinal-fluid Wassermann was negative.

An electrocardiogram showed a tendency to slight right-axis deviation, upright T₁, low T₂, inverted T₃ and T₄ and short Q₄. An x-ray of the chest showed no evidence of disease in the heart or lungs.

A tourniquet test done on the third day was positive. On the eleventh day the bleeding time from the ear was 15½ minutes and from the finger 16½ minutes. The clotting time was about 13 minutes and there was no clot retraction after sixteen hours. A sternal biopsy done on the fourteenth day showed hyperplasia of the marrow. There was increased cellularity, particularly evident in the granulocytic series. Megakaryocytes were also increased, the older forms being predominant. After the biopsy the patient vomited about an ounce of material which appeared to be changed blood. She had begun her menstrual period on the eighth hospital day and continued to flow quite profusely for two weeks. On the fifteenth day the red-cell count was 2,460,000 with 55 per cent hemoglobin. On that day her temperature rose to 101.5°F. Two days later she was given a transfusion of 550 cc of blood, and following that her temperature rose to

acterized by depressed function, particularly so far as platelets are concerned. The petechiae, hemorrhagic skin lesions, profuse menstruation, nosebleeds, hematemesis, hematuria, positive guaiac tests of the stools, positive tourniquet test, prolonged clotting time and lack of clot retraction are part of the syndrome of thrombocytopenic purpura—an organ manifestation of the disease. Thrombocytopenic purpura commonly occurs in lupus erythematosus, and it demonstrates the fact that this type of purpura is but a syndrome of a disease.

So far as involvement of the heart is concerned, there is generalized dilatation. This may have been caused by a pericarditis which is commonly present in the disease. There is no evidence of valvular deformity, nevertheless, nonbacterial verrucose endocarditis (Libman-Sachs syndrome) may well be present. These vegetations may be the result of sensitivity of valves to pressure along the line of closure. The probability of this is about 50 per cent. Whether the right ventricular preponderance is caused by pericarditis or by right-sided hypertrophy and dilatation due to involvement of the vascular and bronchial systems of the lungs cannot be stated with any degree of certainty.

The affection of the kidney is probably caused by arteritis, arteriolitis and vascular thrombotic lesions of the vessels of the glomeruli. I assume that, in spite of the coma, the patient did not die from uremia caused by the nephritis of visceral lupus erythematosus, but rather from a terminal pneumonic process.

I shall now comment on certain instructive features of the case. I am glad to note that the patient did not have a "butterfly distribution" of the skin lesions. This description is overemphasized, and we see it in but one group. The distribution and the sequence of involvement of various skin areas vary considerably. The moist surfaces, including the labia majora, may become involved, as in this case. At times the skin lesions may closely imitate those occurring in acute pellagra. In both diseases there is sensitivity of the skin to certain rays, to pressure and to inflammation in general.

Temperature reactions following transfusion, as in this case, are common in patients with severe blood dyscrasias. At times they precipitate pulmonary edema and coma.

I assume that splenectomy was undertaken because of the presence of thrombocytopenic purpura. This has been done in other cases in the past. It is usually, as in this case, of but temporary benefit. The platelets remained low after splenectomy, but nevertheless the bleeding stopped, indicating that the influence of splenectomy on bleeding does not depend entirely on changes in the number of the platelets.

DR. TRACY B. MALLORY: Dr. Holmes, would you care to commit yourself about the heart—whether it is hypertrophied or whether the apparent enlargement is due to pericarditis?

DR. GEORGE W. HOLMES: The general shape of the heart is that of a dilated heart. A considerable period of time has elapsed since she first began to show enlargement. It certainly is not the shape one would expect to see with hypertrophy of the ventricle. I do not believe we have sufficient evidence to distinguish between fluid and a dilated heart. My guess would be that there is more dilatation than fluid. These films were taken at close range and the heart probably is not nearly so large as it appears to be. One other point—I personally would not make a diagnosis of pulmonary heart disease from these films.

DR. JACOB LERMAN: I first saw this patient in the Out Patient Department, after the initial entrance, merely in a routine check-up. My attention was attracted by the fact that the rash, joint pains and facial swelling persisted. During this time she had taken considerable medication, such as codeine, aspirin and mandelic acid. Dr. Austin W. Cheever was called in to see her. We both agreed that the rash was not a drug eruption but probably of the same nature as the one present during her hospital stay. Consequently a diagnosis of lupus erythematosus was entertained and she was readmitted to the hospital with that diagnosis for further treatment and study.

I agree with Dr. Weiss that she developed the characteristic picture of lupus erythematosus. It was a surprise to hear him discuss the similarity between disseminated lupus erythematosus and pellagra. We have also entertained that idea and feel that a nutritional factor may be of importance in this disease. However, it is difficult to prove.

Another interesting point about lupus erythematosus is the following. Two years ago a patient with the characteristic picture of disseminated lupus erythematosus was found to have lymphoma, post mortem. More recently Dr. Myles P. Baker had a patient with the lesions similar to those of lupus erythematosus, but biopsy of a node showed multiple myeloma. It is possible that disseminated lupus erythematosus may be a manifestation of many diseases and not a disease entity.

DR. JACOB H. SWARTZ: I am not familiar with the case except from the discussion this morning. I am in accord with Dr. Weiss's complete discussion of the case, but I still wonder about drug eruptions. Drugs could give both the blood picture and the skin picture of lupus erythematosus with mucous membrane involvement.

DR. MALLORY: There was no history of taking drugs except what Dr. Lerman has mentioned.

mens likewise contained large amounts. An electrocardiogram on the ninth day showed definite but slight, right-axis deviation. A phenolsulfonphthalein test of kidney function on the eleventh day showed an excretion of 30 per cent in one hour with only 5 per cent excreted in the first fifteen minutes. On the following day the non-protein nitrogen of the blood was 31 mg per cent. Her temperature rose to 101.5°F on that day and until her death, eleven days later, ranged between 100 and 103.5°F. On the fourteenth day her face was somewhat puffy, and she complained of persisting headache. During the next three days the nonprotein nitrogen of the blood serum rose to 58 mg per cent. The blood chlorides were equivalent to 104 cc of N/10 sodium chloride. An x-ray picture of the chest on the sixteenth day showed further marked increase in the size of the heart on both sides. There was slight haziness over the left lower lung field. She became somewhat drowsy, and her heart had a gallop rhythm with many irregular beats. She finally lapsed into coma and died on the twenty-third day.

DIFFERENTIAL DIAGNOSIS

DR SOMA WEISS* In the diagnosis of a case with symptoms and signs related to many organs, three methods of approach are available. In the first place, one can undertake the differential interpretation of a single presenting symptom or sign, drawing in other findings thereafter through a similar analysis. The parallel direction of the interpretations of the clinical findings analyzed suggests the diagnosis. The second method is followed if the entire clinical picture can be translated at once into a single, well-understood physiologic or morphologic mechanism. Finally, there are cases in the diagnosis of which we still follow the time-honored nosologic correlation of clinical symptomatology with postmortem findings. This method is apt to be practiced in the diagnosis of diseases whose nature we do not understand.

In the interpretation of this case I shall follow the last method, first, because after reading the record of this patient a specific diagnosis forced itself upon me and, secondly, because the nature of the disease in question, if I am correct, is but poorly understood and vaguely defined.

A young woman develops fatigue, loss of weight, cough, attacks of tender, hot, swollen joints, sore muscles, fever, persistent skin lesions as described and a hemorrhagic tendency, which is at first slight and later more pronounced. The heart is normal except for a systolic murmur. In the late stage of the disease it becomes enlarged

and right-axis deviation develops. There is secondary anemia with reduced platelets. The bone marrow is hyperactive. Splenectomy is performed, which temporarily abolishes the hemorrhagic tendencies. For several months the patient remains weak, with remissions. Meanwhile, the skin lesions persist and advance. Gradually the hemorrhagic tendency and joint involvement return. Subsequently, generalized lymphadenopathy develops. Density of the basal portions of the lungs increases. Changes in the terminal phalanges of the fingers suggest osteoarthropathy. The sedimentation rate of the blood cells is increased. Blood culture is negative. Albumin appears in the urine and increases in amount. There is a tendency to fixation of the specific gravity of the urine. The nonprotein nitrogen becomes elevated, and the kidney functions impaired. The patient dies in coma after a progressive illness of over a year's duration.

The diagnosis is acute *disseminated lupus erythematosus*. At least, one can state with a considerable degree of clinical certainty that all the features in the case are entirely compatible with this disease. Indeed, it is difficult to find another disease which can explain more than part of the symptoms. Thus I believe, for reasons which because of lack of time I shall omit, that this patient did not suffer from rheumatic fever, subacute bacterial endocarditis, aplastic anemia, nonleukemic myelosis, lymphoma, Boeck's sarcoid or periarteritis nodosa. There may be further discussion about periarteritis nodosa later, but I do not believe that is the diagnosis in a clinical sense. I should prefer to discuss what is meant by the diagnosis of acute disseminated lupus erythematosus and what is the interpretation of the apparently bizarre features of the case in terms of morbid functions and structures.

The diagnosis of acute disseminated lupus erythematosus indicates a disease of unknown etiology with disseminated proliferative lesions of the minute blood vessels and lymphatics with a tendency to secondary thrombosis in these vessels. The disease is often associated with inflammation and proliferation of the surfaces of the serous cavities and the endocardium, and with thrombopenia.

In this particular case the lesions of the skin were rather widespread and characteristic, those of the bone marrow resulted in the clinical picture of thrombopenic purpura, those of the lymphatic system caused generalized lymphadenopathy, those of the heart resulted in dilatation, and those of the kidney produced a special form of vascular nephritis with glomerulitis, perhaps the disease also affected the lungs and certain serous surfaces.

Many of the outstanding features of the case are referable to disturbances of the bone marrow char-

*Associate professor of medicine Harvard Medical School assistant director Thorndike Memorial Laboratory Boston City Hospital

rule, and I back up this statement by the following facts. I am glad that Dr. Lerman has raised the question whether lupus erythematosus is anything but a reaction of the body to different agents. There is considerable evidence for that concept, nevertheless, as we see it clinically, lupus erythematosus is characterized by such widespread and specific involvement of internal organs and of the skin that it deserves the distinction of being called a syndrome or a disease. In this disease, vascular lesions are known to occur, and they can be one or another form of arteritis. A few cases of lupus erythematosus disseminatus with periarteritis-nodosa-like lesions have been reported in the literature. Therefore, the question arises whether it is more justifiable to correlate all the changes and make one diagnosis, or to pick out a few scattered vascular lesions and call that a disease. Certainly periarteritis nodosa is much less of a specific reaction than the syndrome of lupus erythematosus, because the more we see of periarteritis nodosa, the more we are impressed by the fact that it can occur as widespread lesions or as a local manifestation in one organ. It is found in rheumatic fever and frequently the patient recovers. I should like to know whether Dr. Mallory agrees with this reasoning.

DR. MALLORY: I believe that the question has to be left open. I think it is utterly impossible from a postmortem examination to rule out lupus erythematosus.

CASE 24202

PRESENTATION OF CASE

A thirteen-year-old, white, American schoolgirl entered the hospital with the complaint of cough and chest pain of nine weeks' duration.

Nine weeks before entry she began to have pleuritic pain in the right upper chest anteriorly, accompanied by a mild unproductive cough and beginning weakness. The symptoms continued for two weeks, and during that period she lost about 12 lb in weight. Her physician made a diagnosis of pneumonia and kept her in bed. At the end of the two weeks her chest pain disappeared entirely, but the cough, although lessened, continued practically unchanged. For the next month she was studied in an outside hospital. During that time she gradually regained some of her strength and weight. No treatment was given to her during that period. Three weeks before entry she returned home feeling reasonably well except for some persisting weakness and the continued cough. However, her physician would not allow her to return to school, and she was finally referred to this hospital for treatment. Her past history and family history were essentially negative.

She did not have frequent colds or sore throats, and she had not been exposed to tuberculosis.

Physical examination revealed a well-developed but somewhat undernourished girl in no apparent distress. The trachea was in the midline but moved to the right on deep inspiration. The right chest expanded less than the left, and breath sounds and resonance were diminished over its entire area. No definite dullness or rales could be heard. The heart was apparently shifted to the right but was otherwise negative. The blood pressure was 116 systolic, 70 diastolic. The abdomen was negative.

The temperature was 98.6°F., the pulse 90. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 4,830,000 with 89 per cent hemoglobin, and a white-cell count of 6400 with 50 per cent polymorphonuclears. The blood Hinton test was negative.

An x-ray of the chest showed displacement of the heart to the right and a definite expiratory shift to the left. There were bands of increased density in the right apical field. Within the right main bronchus there was a mass measuring 1.0 by 1.5 cm. which protruded far into the bronchus. Lipiodol studies were somewhat unsatisfactory because most of the lipiodol lodged below the mass. However, the mass seemed to be coated by it and appeared to arise from the right anterior aspect of the right main bronchus at the level of the carina with perhaps some protrusion into the trachea. Its lower margin lay close to the upper lobe bronchus.

On the eleventh day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. CHARLES L. SHORT: This patient's history is essentially that of a pulmonary infection and does not give us much of a lead in diagnosis. Of course, such a history could be presented and often is by a patient who has a new growth in the lung. New growths, by obstructing the bronchi, frequently are the indirect cause of persistent infection in the distal portions of the lung. There is no mention of how much fever she had during her illness previous to admission. It says she had no sputum, which would be against a suppurative lesion of any extent, such as lung abscess, either with or without a foreign body, or bronchiectasis. She apparently had no hemoptysis. The physical examination is essentially that of partial obstruction to the right main bronchus. We find the right chest expanding less than the left. We have less air coming into the right lung and a shift of the heart to the right and some shift of the trachea to the right on inspiration. I think that is about

DR. JAMES H. MEANS It is interesting that she had syphilis. I suppose it had nothing to do with the present situation, but I should like to take note of it. At least she had positive Hinton and negative Wassermann tests, and is known to have had syphilis. I am also interested in what Dr. Lerman has said about this disease that we call lupus erythematosus to the effect that it may be a symptom of various diseases. I wonder if it ever might be a symptom of syphilis or of the combination of syphilis and toxic effect from anti-syphilitic treatment. I do not know why it should. I simply mention the possibility.

CLINICAL DIAGNOSES

Disseminated lupus erythematosus
Uremia
Terminal pericarditis
Latent syphilis

DR. WEISS'S DIAGNOSES

Acute disseminated lupus erythematosus with thrombocytopenic purpura, cardiac dilatation, vascular nephritis with arteritis and glomerulitis, mediastinopericarditis (?), nonbacterial verrucose endocarditis (?) and pulmonary involvement with vascular changes (?)
Terminal pneumonia

ANATOMICAL DIAGNOSES

(Acute disseminated lupus erythematosus)
Periarteritis nodosa
Bronchopneumonia
Hydrothorax
Hydropericardium
Purpura
Operation wounds: splenectomy, sternal biopsy, liver biopsy

PATHOLOGICAL DISCUSSION

DR. MALLORY From the pathologist's point of view lupus erythematosus is one of the most unsatisfactory diagnoses that he is ever called upon to confirm at autopsy. Dr. Weiss has mentioned a variety of vascular lesions which have been reported from time to time. Very few of them, however, are to be found in the average case. There is no visceral lesion as yet recognized which is constantly present in every case. A significant proportion show a lesion in the kidney which Baehr and Klemperer described and called a "wire loop lesion,"—a thickening of individual capillary walls in certain portions of each glomerular tuft,—but in my experience many fatal cases of lupus erythematosus do not show it. Indeed we have found it in less than half of ours, whereas Baehr

and Klemperer found it in considerably more than half of theirs. Also in the disease one finds lesions of larger blood vessels but they are not particularly common or at least in the course of looking through the average number of routine sections from an autopsy one is not apt to find such lesions. When one does find them they are somewhat variable in character, and I do not believe that anatomically they are specific. It is therefore impossible for the pathologist to say that Dr. Weiss's diagnosis is wrong, and yet I reached another diagnosis, which was periarteritis nodosa.

During the patient's life we had had opportunity to examine the spleen and also biopsies from the liver and the bone marrow. We could find no significant abnormalities.

Grossly, at autopsy, we found a normal-sized heart and a large pericardial effusion, which consisted of slightly turbid fluid. The kidneys showed slight abnormalities. The radial arteries seemed to be particularly prominent, and we found scattered petechial hemorrhages in the kidneys, throughout the gastrointestinal tract, and of course also in the skin, where they had been noted before autopsy. We were unable to make a diagnosis grossly and adopted the clinical diagnosis of lupus erythematosus which seemed to cover very satisfactorily all features of the case, but when the histologic preparations came through we found multiple arterial lesions in virtually every organ in the body. There were one or more involved vessels in every section of tissue which we made except in the lungs and in the skin. There I could find no arterial lesions. There was also a terminal pneumonia. The skin changes of edema, keratosis of the mouths of the coil glands, degeneration of the basal layer and slight lymphocytic infiltration are characteristic of lupus erythematosus. Since I am no dermatologist I should like to record that Dr. Hamilton Montgomery of the Mayo Clinic confirmed my impression of the skin slides. The lesions in the blood vessels were those of a periarteritis. There was necrosis of the media, intimal proliferation and sometimes thrombosis, and a small periarterial accumulation of cells, chiefly plasma cells, some monocytes, some erythrocytes, but very few eosinophils. So far as one individual lesion is concerned, I have seen something much like it in lupus erythematosus but I have never heard of lupus erythematosus with such extensive involvement of vessels.

DR. WEISS At times the question arises whether we should accept the pathologist's or the clinician's diagnosis. We usually accept the pathologist's diagnosis as the final verdict. Without presumption on my part, however, I venture to say that in this instance the clinical diagnosis should

nite diagnosis of fibrosarcoma by biopsy, the only possible treatment seemed to be extirpation, probably of the entire lung. The girl was anesthetized and the right pleural cavity opened. The right lung was found to be blown up as tightly as a drum, and no air could be pressed out of it. I was beginning to worry about what I was going to do in order to reach the hilum around this tightly blown-up lung when the patient had a profuse hemorrhage from within into her bronchial tree which flooded the other lung with blood. She died, presumably of a hemorrhage originating at the point of the endobronchial tumor. In retrospect or in facing another case with retention emphysema of the lung, I think that I certainly should make every effort to have the bronchus cleared by bronchoscopy before attempting pneumonectomy. However, the fatal hemorrhage might very well have followed bronchoscopic removal of the growth.

PREOPERATIVE DIAGNOSIS

Fibrosarcoma of right main bronchus (by bronchoscopic biopsy)

DR. SHORT'S DIAGNOSIS

Adenocarcinoma of the bronchus

ANATOMICAL DIAGNOSES

Fibrosarcoma of right main bronchus with ulceration

Chronic pneumonitis, slight

Fatal bronchial hemorrhage

Functional emphysema

PATHOLOGICAL DISCUSSION

DR. MALLORY: At postmortem examination we found the cause of the sudden hemoptysis or at least what seemed so to us. The major part of

the tumor, which was 5 mm. in diameter was lying perfectly free in the bronchus. It had evidently ulcerated off its base, and I think we have reason to believe that it had done so in the last few minutes before death because the cells in it were perfectly preserved. If the ulceration had occurred a few hours before, the tumor would probably have been expectorated, or if it had been retained in the bronchus, it would have begun to show signs of cytolysis or postmortem degeneration, which was not present. We found an erosion in the mucosa of the bronchus, which I think was without question the point at which the tumor had broken off, since in the bronchial wall beneath it there was persistent tumor. Our sections of the tumor are essentially the same as those of the bronchoscopic specimen removed at the other hospital. It was quite evident that it was a spindle-cell sarcoma growing at a moderate rate. It was definitely invasive at the base. There could be no question of its malignancy, and there was no possibility of cure except by pneumonectomy.

A PHYSICIAN: Were the glands involved?

DR. MALLORY: They were negative, as you would expect with sarcoma.

A PHYSICIAN: Were they enlarged?

DR. MALLORY: Yes, and throughout the right lung there was evidence of a certain amount of chronic infection. The lymphoid tissue in the parenchyma of the lung, for instance, showed definite hypertrophy, and the interlobular septa were edematous.

DR. CHURCHILL: About how far below the carina of the trachea was the point of attachment?

DR. MALLORY: It was just at the first bifurcation of the right bronchus.

DR. CHURCHILL: We could have reached it?

DR. MALLORY: Yes.

as far as we can go without the aid of the x-ray. We can simply say that the patient has a story which suggests an infectious pulmonary lesion but does not rule out a neoplastic process, and that on physical examination she has signs of partial obstruction of the right main bronchus.

X-RAY INTERPRETATION

DR AUBREY O HAMPTON These films were taken at intervals over a period of two months. The first ones were taken at another hospital before bronchoscopy and show collapse of the right upper lobe and partial collapse of the right middle and lower lobes. The interspaces are narrowed on the right. The diaphragm is elevated, and the heart is displaced to the right. Nine days later the picture has changed. There is a little more collapse of the right lung, and a film six days later shows a further change—the right lung shows more air than it did. Then after bronchoscopy at another hospital these final pictures were obtained at this hospital. This first film was taken at expiration and shows quite a normal-looking chest, in fact if only that view had been taken the chest would have passed as normal with the exception of a few lines at the right apex. But the precaution was taken of making a second film on inspiration, and it shows shift of the mediastinum on the right side. Finally, if you look at the lateral view you can faintly see a round white mass in the region of the bifurcation of the trachea.

DR SHORT Is that before lipiodol?

DR HAMPTON Yes.

DR SHORT That was not clear in the record.

DR HAMPTON It was more distinctly seen before lipiodol injection because of the quality of the film and the position in which it was taken. With the catheter in position at the time they injected lipiodol you can see that the catheter meets an obstruction in the right main bronchus. A smooth round mass extends from the carina downward.

DIFFERENTIAL DIAGNOSIS (continued)

DR SHORT The story of the bronchoscopy at the other hospital introduces an additional element which was not in the history, but I shall go ahead, without paying any attention to it, with the facts that are in the history here. The x-rays certainly bear out the clinical impression that she had obstruction to the right main bronchus and, furthermore, establish the fact that there was an actual mass in the bronchus. I think that this positive finding rules out any of the ordinary pulmonary infections, and we do not have to consider pneumonitis, lung abscess or bronchiectasis. To take up some other infections, I believe it is pos-

sible for syphilis to give a granulomatous type of mass in the bronchus, but I am sure it is very rare, and this patient had a negative Hinton test. I do not believe that sarcoid or yeast infection could give this picture. I think we do have to pause for a while on tuberculosis. She had no signs by x-ray of any parenchymatous involvement. She could conceivably have tracheobronchial tuberculosis with a granulomatous type of lesion in the main bronchus causing a partial bronchial obstruction. I believe, however, that she should show other signs of tuberculosis if that were the case, probably parenchymal tuberculosis, and have a positive sputum. So I think we can mention that in passing as an interesting possibility.

Could this mass represent a foreign body? There is no history of aspiration of a foreign body, no history of operation on the upper respiratory tract before the onset of symptoms, and if she had had a foreign body, she would probably have had more of a suppurative process. We are left with a consideration of this mass as representing a neoplasm in the bronchus. I do not know how we can say what type of neoplasm it is without more definite information. Perhaps this was discovered at the other hospital by biopsy at the time of bronchoscopy. She has had no bleeding, which would be somewhat against her having a benign polyp. Of course, the child's age is against a malignant growth of the bronchus, but I believe such cases have been reported in children and in young adults. We have no evidence as to whether she had a benign growth, such as a fibroma or lipoma, or the so-called benign adenoma. The most common new growth in this situation would be an adenocarcinoma of the bronchus. The history, as I mentioned before, is not against this diagnosis. She may have had the tumor a long while before she had symptoms, as we sometimes see metastases in the brain in patients with carcinoma of the bronchus before any suspicion has been directed toward the lung. If this is the diagnosis, there are no signs or evidence of metastases. Simply because this is the most common new growth in such a situation, I will say it is an adenocarcinoma of the bronchus.

DR TRACY B MALLORY The case was presented to us in slightly different form, the patient was sent to us with the diagnosis already made by bronchoscopy. The diagnosis was fibrosarcoma, which seemed very astonishing as we had never seen or heard of primary fibrosarcoma of the bronchus, but an excellent slide which was sent to us enabled us to confirm the diagnosis.

DR CHURCHILL, would you like to make a comment?

DR EDWARD D CHURCHILL Having the defi-

nite diagnosis of fibrosarcoma by biopsy, the only possible treatment seemed to be extirpation, probably of the entire lung. The girl was anesthetized and the right pleural cavity opened. The right lung was found to be blown up as tightly as a drum, and no air could be pressed out of it. I was beginning to worry about what I was going to do in order to reach the hilum around this tightly blown up lung when the patient had a profuse hemorrhage from within into her bronchial tree which flooded the other lung with blood. She died, presumably of a hemorrhage originating at the point of the endobronchial tumor. In retrospect or in facing another case with retention emphysema of the lung, I think that I certainly should make every effort to have the bronchus cleared by bronchoscopy before attempting pneumonectomy. However, the fatal hemorrhage might very well have followed bronchoscopic removal of the growth.

PREOPERATIVE DIAGNOSIS

Fibrosarcoma of right main bronchus (by bronchoscopic biopsy)

DR. SHORT'S DIAGNOSIS

Adenocarcinoma of the bronchus

ANATOMICAL DIAGNOSES

Fibrosarcoma of right main bronchus with ulceration

Chronic pneumonitis, slight

WHEELER-LEA ACT

THE Wheeler-Lea Act to control false and fraudulent advertising of foods, drugs and cosmetics was recently passed by Congress and signed by the President. This bill is complex and difficult to understand. It would seem to control satisfactorily, with proper penalties, this extremely important matter of false and fraudulent advertising, but there is considerable doubt as to whether the purpose of the bill will be accomplished. In the first place it brings in a divided responsibility inasmuch as the enforcement of the provisions of this bill is placed in the hands of the Federal Trade Commission, while the other control of drugs, foods and cosmetics presumably will remain in the hands of the Food and Drug Administration of the Department of Agriculture, where it was placed in 1906 under the original

Food and Drug Act. In the second place it seems that the procedures to be followed under this proposed bill by the Federal Trade Commission lend themselves particularly well to delay and evasion. In the third place past experience suggests that the Federal Trade Commission will not enforce the necessary procedures effectively.

Why was such a bill written and approved? The proper answer seems to be that powerful business interests of the trade in drugs and cosmetics saw in this method an escape from the more effective provisions contained in a bill (Senate 5) passed in the Senate, which placed all phases of control under the Food and Drug Administration. Perhaps the trade thought it wiser not to antagonize the medical and lay public by an open attack on the latter bill and to seem to favor control without actually allowing control. If so, they could hardly have taken a better way. The medical profession has used its influence for an adequate control; it seems that it has lost out. Even the provisions of the old Food and Drug Act were better than those of the new, unless the Federal Trade Commission awakens to the fact that the trade has pulled its leg and vigorously enforces these regulations against false and fraudulent advertising by minimizing the possible delays and by imposing maximal penalties. We await with curiosity to see how this new act will be made to work.

THE COMMONWEALTH FUND

THE Commonwealth Fund of New York has recently released its nineteenth annual report. Originally endowed by Mrs. Stephen V. Harkness in 1918, the fund has, during the past year, been the recipient of two gifts from its president, Edward S. Harkness, totaling \$8,000,000 and bringing the total endowment of the fund to over \$50,000,000. Of Mr. Harkness's recent gifts it is planned for the present to devote the income from \$3,000,000 to the development of rural hospitals, and that from \$5,000,000 to medical education and research.

Grants of approximately \$1,800,000 were made from current income in the year ending Septem-

ber 30, 1937, going toward a variety of useful purposes. The fund has already been responsible for the building of ten community hospitals in rural communities, eight of which are already in operation. These well-equipped hospitals of approximately fifty beds are located in Maine, Ohio, Virginia, Kentucky, Mississippi, Oklahoma, Kansas and Utah, with two in Tennessee.

The value of these hospitals to their communities can hardly be estimated, but they are also serving another purpose in which the fund is keenly interested—the attracting to small communities of well-trained young physicians. Fifty young physicians have already settled in the vicinity of the first six of these institutions, and as a further step in this direction a number of scholarships have been provided at Vanderbilt University, Tulane University and Tufts College medical schools. In addition more than 400 fellowships have been made available to older men in practice who wish to brush up on current medical information.

In the department of medical education, funds have been provided to strengthen the teaching of preventive medicine at Vanderbilt, Tulane and Tufts, at Tulane the expansion of the Department of Pediatrics has been aided, at Cornell, Columbia and Harvard the fund has helped to finance teaching clinics for emotional and behavior problems. The teaching and the study of psychiatry have been assisted at the University of Louisville, Johns Hopkins and the University of Colorado.

The fund has aided medical research in general in a number of medical schools and hospitals, selecting problems that give promise of contributing sooner or later to better medical practice. Thus, during the past year, seven new undertakings have been selected for subsidy in addition to those carried forward from previous years. Public health

has been aided in Tennessee and Mississippi by the provision of traveling units to advise local health units, and in Massachusetts by a tuberculosis eradication campaign in a Berkshire County district.

These activities do not close the list of the fund's philanthropies. A child-guidance clinic is still being supported in London, problems in legal research are being studied, and a number of Brush fellowships are supported.

The time may be at hand when it will be necessary for public funds to underwrite medical education and scientific research, but if the independence, initiative and integrity of private philanthropy that are exemplified by the activities of the Commonwealth Fund disappear, medicine will be the loser.

MASSACHUSETTS MEDICAL SOCIETY

ANNUAL MEETING OF THE COUNCIL

The annual meeting of the Council will be held in the Penthouse of the Hotel Bradford, Boston, on Wednesday, June 1, at 10.30 a m.

Business

- 1 Reading record of last meeting in abstract
- 2 Nominating Committee retires to deliberate
- 3 Report of Committee on Membership and Finance
- 4 Reports of committees to consider petitions for restoration to the privileges of fellowship and new committees to be appointed
- 5 Reports of standing committees and special committees
- 6 Election of officers and orator by ballot
- 7 Appointment of committees for ensuing year, both standing and special
- 8 Proposed changes in by-laws
- 9 Incidental business

ALEXANDER S BEGG, *Secretary*

Councilors are asked to sign one of the two attendance books before the meeting. The Cotting Luncheon will be served immediately after the meeting.

WHEELER-LEA ACT

THE Wheeler-Lea Act to control false and fraudulent advertising of foods, drugs and cosmetics was recently passed by Congress and signed by the President. This bill is complex and difficult to understand. It would seem to control satisfactorily, with proper penalties, this extremely important matter of false and fraudulent advertising, but there is considerable doubt as to whether the purpose of the bill will be accomplished. In the first place it brings in a divided responsibility inasmuch as the enforcement of the provisions of this bill is placed in the hands of the Federal Trade Commission, while the other control of drugs, foods and cosmetics presumably will remain in the hands of the Food and Drug Administration of the Department of Agriculture, where it was placed in 1906 under the original

Food and Drug Act. In the second place it seems that the procedures to be followed under this proposed bill by the Federal Trade Commission lend themselves particularly well to delay and evasion. In the third place past experience suggests that the Federal Trade Commission will not enforce the necessary procedures effectively.

Why was such a bill written and approved? The proper answer seems to be that powerful business interests of the trade in drugs and cosmetics saw in this method an escape from the more effective provisions contained in a bill (Senate 5) passed in the Senate, which placed all phases of control under the Food and Drug Administration. Perhaps the trade thought it wiser not to antagonize the medical and lay public by an open attack on the latter bill and to seem to favor control without actually allowing control. If so, they could hardly have taken a better way. The medical profession has used its influence for an adequate control, it seems that it has lost out. Even the provisions of the old Food and Drug Act were better than those of the new, unless the Federal Trade Commission awakens to the fact that the trade has pulled its leg and vigorously enforces these regulations against false and fraudulent advertising by minimizing the possible delays and by imposing maximal penalties. We await with curiosity to see how this new act will be made to work.

— ASSIGNMENTS OF COMMITTEEMEN AND AIDS

TUESDAY — MAY 31

MORNING

Section of Surgery—Dr. Augustus Thorndike, Jr., in charge.

Aids—Dr. J. A. Halsted, Dr. Harrison Kennard

Section of Pediatrics—Dr. R. P. Stetson, in charge.

Aids—Dr. J. R. Graham, Dr. G. P. Sturgis

AFTERNOON

Section of Dermatology and Syphilology—Dr. W. T. O'Halloran, in charge

Aids—Dr. F. M. O'Connor, Dr. William Egan

Section of Obstetrics and Gynecology—Dr. E. J. O'Brien, Jr., in charge.

Aids—Dr. T. E. Caulfield Jr., Dr. J. A. Hennessy

EVENING

Shattuck Lecture—Dr. W. S. Burrage, in charge

Aids—Dr. G. D. Krumbhaar, Dr. Lendon Snedeker

— WEDNESDAY — JUNE 1

MORNING

Council Meeting—Dr. E. J. O'Brien, Jr., in charge.

Combined Clinical Meeting—Dr. Augustus Thorndike, Jr., *Chairman*

Dr. W. T. O'Halloran, in charge of morning session

Aids—Dr. F. M. O'Connor, Dr. William Egan, Dr. G. D. Krumbhaar, Dr. Lendon Snedeker

Dr. R. P. Stetson, in charge of afternoon session

Aids—Dr. J. R. Graham, Dr. G. P. Sturgis, Dr. J. A. Halsted, Dr. Harrison Kennard.

AFTERNOON

Golf Tournament—Dr. W. T. O'Halloran, in charge.

EVENING

Annual Dinner—Dr. R. P. Stetson, in charge.

Aids—Dr. J. R. Graham, Dr. G. P. Sturgis

THURSDAY — JUNE 2

MORNING

Section of Medicine—Dr. W. T. O'Halloran, in charge.

Aids—Dr. F. M. O'Connor, Dr. William Egan

Section of Radiology and Physiotherapy—Dr. R. P. Stetson, in charge.

Aids—Dr. J. R. Graham, Dr. G. P. Sturgis

NOON

Annual Meeting and Oration—Dr. W. S. Burrage, in charge

Aids—Dr. G. D. Krumbhaar, Dr. Lendon Snedeker

— GENERAL INFORMATION —

All meetings, commercial and scientific exhibits, clinical meetings, luncheons and dinner will be held in the Hotel Bradford.

A *Bureau of Information* will be maintained at the Registration Desk on the stage of the Ballroom. Physicians expecting to receive telephone calls should leave proper information with the hotel operator.

Fellows are requested to register as soon as they arrive and to get tickets for the Annual Dinner and for the Thursday Luncheon. The charge for the Annual Dinner will be \$1.00 to those who are not in arrears and the Thursday Luncheon will be without charge to those whose dues have been paid.

The *scientific exhibits* are located in the balcony of the Ballroom.

The *commercial exhibits* are all located in the Ballroom.

The *Physicians Art Society* will hold an exhibition throughout the meeting in both the Men's and Women's Lounge.

Free parking for members' cars has been provided in the parking lot on Hollis Street, directly opposite the hotel.

Golf Tournament There will be a golf tournament for members on Wednesday afternoon, June 1, at the Commonwealth Country Club, 91 Algonquin Road, Newton Centre. Information and instruction sheets may be procured at the Registration Desk.

MEETINGS OF THE COUNCIL

The annual meeting of the Council, Wednesday, June 1, at 10.30 a m., in the Lobby Salon Other stated meetings in John Ware Hall, Boston Medical Library, 8 Fenway on the first Wednesdays of October and February

CENSORS MEETINGS

The censors for the several districts will meet for the examination of applicants for fellowship on the first Thursdays of May and November

The censors for the Suffolk district will examine applicants residing in that district and also applicants who are nonresidents of Massachusetts

Applicants for fellowship should apply to the secretary of the district society of the district in which they reside (have a legal residence), at least six weeks before the date of a given examination, taking with them their diplomas

SECRETARY S NOTICE

All communications as to membership, especially changes of residence and address, should be sent to the Secretary, who keeps a constantly corrected official list of the fellows and their addresses

Fellows are requested to see that their names and addresses are entered correctly in the *Annual Directory* and when they move to notify the Secretary The *Annual Directory* will be sent only to paid up fellows who request it.

TREASURER'S NOTICE

Assessments, payable in advance, should be paid to the district treasurer, or, in the case of nonresidents, to the Treasurer

Assessments were due January 1 For the convenience of fellows who have not yet paid, such assessments will be received for the Treasurer at the Registration Desk.

COMMERCIAL EXHIBITS

Table No

1 The Alkalol Company, Taunton, Massachusetts

Alkalol is an alkaline, saline solution. The pH test shows that the hydrogen ion concentration of Alkalol closely approximates that of the blood plasma. Alkalol is hypotonic. Alkalol does not irritate. Its use is indicated in inflammatory lesions of the eye, ear, nose, throat, bladder and vagina. It is a mucus solvent.

Irrigol is a carefully blended powder which dissolved in recently boiled water makes an alkaline, aseptic, non toxic and slightly astringent solution. It is a cleansing and soothing irrigant for vaginal douching, colonic flushing, rectal enemas or wherever copious irrigation is desired.

2. Baby's Dy Dee Service, Incorporated, Brookline, Massachusetts

This exhibit will explain in detail the specialized equipment and the methods used in sterilizing and supplying diapers to homes in Greater Boston. Starting a fifth year this service has relieved hundreds of mothers and nurses of the daily drudgery of washing diapers and baby clothes, at the same time protecting baby's health by a scientific process impossible at home. An economical service devoted exclusively to the baby.

3 The Liebel Flarsheim Company, Cincinnati, Ohio

Will exhibit short-wave generators as well as Bovie electrosurgical units. L-F equipment is the product of electromedical specialists in business over twenty years. L-F electrosurgical apparatus has for many years been regarded generally as most dependable and is now in use by leading institutions and surgeons throughout the world.

Mr Arnold Williams will be in charge.

Booth No

1 The C B Fleet Company, Incorporated, Lynchburg, Virginia

Phospho-Soda (Fleet) has come to occupy a significant position wherever sodium phosphates or other laxative salines are indicated. It is a pure, stable aqueous concentrate of sodium phosphates with a history of forty-five years of manufacture.

The C B Fleet Company takes this opportunity to thank the medical profession for the broad usage and increasing recognition given to their single product, Phospho-Soda (Fleet). It is offered as an eliminant, with the advantages of ease of administration, rapidity and smoothness of action, and of being a buffer solution.

Mr R. S. Carman, New England representative, will be in charge.

2 Mead Johnson & Company, Evansville, Indiana

Mead Johnson & Company are distributing this year an unusually fine souvenir item. It is not only beautiful but extraordinary because it contains no advertising. Ask for your copy of 'Paragon'.

The complete display of Mead products includes two new ones.

3 Winthrop Chemical Company, Incorporated, New York City

Details regarding the new specifics for streptococcal, meningococcal, gonococcal and nonspecific urinary infections, Prontosil and Prontylin, will be available in the Winthrop Chemical Company's booth. Other new Winthrop preparations to be displayed: Betaxin, synthetic vitamin B₁, Drisdol, crystalline vitamin D₂, Evicyl, sedative analgesic, Iocapral, vasodilator for hypertension and angina pectoris, Campolon, injectable liver concentrate.

4 American Hospital Supply Corporation, Chicago

If you are planning to visit the annual meeting of the Massachusetts Medical Society be sure to save plenty of time to see what is waiting for you at Booth 4. The American Hospital Supply Corporation is showing an unusually interesting array of brand new specialties in surgical and hospital equipment. You are sure to come away with some new ideas about oxygen therapy, intravenous solutions, blood transfusions and a lot of other important phases of your work. Mr. Watson E. Hovis will be glad to see you and show you around. Remember you have an appointment at Booth 4.

5 Libby, McNeill & Libby, Chicago

Baby's first solid foods should be well tolerated and easily digested. Libby's Homogenized Baby Foods are ideal for early feeding because in addition to being strained they are given an extra process—homogenization. We invite you to visit the Libby exhibit to sample fruit juices and to register for samples of Libby's Baby Foods.

6 Rudolph Beaver, Incorporated, Waltham, Massachusetts

The important things that make good surgeons' knife blades are proper heat treating of steel, and a good sharpening process. These have been achieved in the Beaver Knife, made by Rudolph Beaver, Incorporated. Beaver blades are not wafer blades, but are strong and thick blades. The mechanism is the simplest and best. All the various blade shapes fit the different stainless steel handles. They are approved by the American College of Surgeons.

7 Surgeons and Physicians Supply Company, Boston

The Surgeons and Physicians Supply Company will exhibit the Comrex Short Wave Outfit, manufactured by the American Cystoscope Makers, Incorporated, and also a line of cystoscopes and catheters manufactured by them. They will also exhibit the new McKesson Pneumothorax, the new Castle office light and a line of new and interesting instruments and accessories.

8 Jones Metabolism Equipment Company, New York City

The Jones Motor Basal is the only waterless metabolism machine on the market. These features enable us to guarantee the machine for the life of the original purchaser. No corrections or calculations for barometric pressure or room temperature are required. No calculations are required to determine the basal metabolism. An exclusive geometric device checks the accuracy of each test. Saving in cost of oxygen, soda lime and tracing sheets pays for the entire cost of the machine.

9-10 United Fruit Company, New York City

You are cordially invited to visit the United Fruit Company's booths and sample a refreshing, banana milk shake, made before your very eyes from fresh ripe bananas mixed with cold milk and vanilla ice cream. Here also you will find the latest information, developed by research, on the food value and the varied uses of bananas.

11 Merck & Company, Incorporated Rahway, New Jersey

Vitamin C, an essential dietary constituent, will be the featured display at the Merck booth.

Individuals who are on a restricted diet frequently require a supplemental quantity of vitamin C. To be positive that they obtain the necessary amount and to be assured that the benefit of accurate dosage is derived, vitamin C is best prescribed in the form of Cebione. Cebione is the only vitamin C available that is Council accepted.

For information regarding Cebione, please register at the Merck booth.

12 The Macmillan Company, New York City

Our representative will be glad to discuss with you any of our recent books in the fields of medicine and surgery. You will want to see particularly our three new Macmillan medical monographs—*Digestive Tract Pain* by Chester M. Jones of the Massachusetts General Hospital, *Leukemia and Allied Disorders* by Claude E. Forkner, and *Orthodiagnosis* by Chester M. Kurtz. Also a Macmillan surgical monograph published recently—*Arteriovenous Aneurysm* by Emile Holman. You will be interested, too, in many of our new books of a more general nature, such as *Syphilis, Gonorrhea and the Public Health* by Nels A. Nelson and Gladys L. Crain, both of the Massachusetts Department of Public Health, *Alcohol One man's meat*, by Edward A. Strecker and Francis T. Chambers, Jr., *The Conquest of Cholera* by J. S. Chambers, and *The Life of Chevalier Jackson—An autobiography*.

Mr. Frank G. Hatfield will be our representative.

13 The DeVilbiss Company, Cleveland, Ohio

The complete DeVilbiss line of atomizers, steam vaporizers and nebulizers will be on display. Specially featured in the exhibit are illustrations graphically showing the superior coverage afforded by the atomizer in the application of solutions to the nose and throat. These illustrations are based on x-ray research.

Copies of the illustrations, for reference, may be secured from Mr. E. Manning, DeVilbiss representative in charge of the display.

14 Lederle Laboratories, Incorporated, New York City

Lederle Laboratories, Incorporated, will exhibit biological and pharmaceutical specialties of particular interest. Featured biologicals will be the newer types of pneumonia serum available and scarlet fever antitoxin. The pharmaceuticals to be emphasized will be liver extracts showing the new U.S.P. units.

15 Allerga Products Company, Newton, Massachusetts.

The exhibit of Allerga Bedding intended for the relief of sufferers from asthma, hay fever and related disorders will include a demonstration of dust pro-

duced by ordinary bedding fillers—cotton, kapok, feathers and hair—and will, by comparison, show the dust-free qualities of Allerga pure silk, filling material.

The exhibit will also feature full sized, non-atopic dust-free Allerga Pillows and a model of the dust-free Allerga Mattress.

We shall invite physicians to avail themselves of free vials of an extract made from Allerga Filling Material for their use in making scratch tests.

Of unusual interest, we believe, is our demonstration, which shows kapok (erroneously called silk floss) to be fully as prolific a dust producer as any other bedding filler, yet which for many years has been mistakenly recommended to dust sensitive patients.

Included with our showing of dust-free Allerga bedding is the Kantwet Crib Mattress, which not only offers a wetproof non rubberized infant bedding piece, but also a dustproof protection to sensitive nasal membranes.

16 Mellin's Food Company, Boston

Fitting the food to the baby, the correct approach to bottle feeding, is the underlying principle of the easily workable method that employs Mellin's Food as the milk modifier. A discussion of this matter with physicians is sincerely desired, and your visit to the Mellin's Food Company's exhibit will be greatly appreciated.

17 Bard Parker Company, Incorporated, Danbury, Connecticut

Among the Bard Parker products exhibited are rib-back blades, renewable-edge scissors, stainless steel, Lahey, lock forceps, Formaldehyde Germicide, containers for rustproof sterilization of surgical instruments and a hematological case for obtaining blood samples at the bedside.

18 Crosbie Macdonald, Boston.

Insurance service for members of the Massachusetts Medical Society.

Ask us to explain our plan for your own old age. Mr. Crosbie will be in charge.

19 E. F. Mahady Company, Boston.

The E. F. Mahady Company exhibit will include recent developments of the Burdick Company in the field of physical therapy, a display of Cutter Intravenous Solutions in Safteflask containers, and other items of interest to the medical profession.

20-21 Burroughs Wellcome & Company, Incorporated, New York City

The Burroughs Wellcome & Company exhibit presents a wide range of new and important advances in pharmacological and chemical research.

22 General Electric X-Ray Corporation, Boston

It is the policy of the General Electric X-Ray Corporation to try, at each meeting of the Massachusetts Medical Society, to have an interesting exhibit for the visiting doctor. All we ask is that he pay us a visit and meet our representatives who are very helpful in the matter of x-ray and physical therapy problems.

23 The E. L. Patch Company, Stoneham, Massachusetts

The Patch Company representatives will be on hand throughout the convention ready to greet physicians and to be of service in any way. The Patch Com-

pany exhibit will include Patch's Cod Liver Oil, as well as the other ethical medicinal specialties made in the Patch Laboratory

- 24 The Arlington Chemical Company, Yonkers, New York.

The Arlington Chemical Company will again exhibit its products at the annual meeting of the Massachusetts Medical Society. It will again feature its biological and pharmaceutical products. The company is offering a new diagnostic protein outfit that has just been released consisting of eighty of the most common causative factors in allergic conditions. The physician in charge of the booth will be happy to discuss any allergic problem.

- 25 26 Picker X Ray Corporation, New York City

The Waite Series "200" Radiographic and Fluoroscopic X-Ray Apparatus will be displayed. This is the first completely self-contained, oil immersed valve tube equipment to be presented to the radiographic profession. The new Waite Series "200" delivers 200 ma. from over as well as under the table, and is instantaneously available for radiography or fluoroscopy either in the horizontal or vertical position. It is self-contained by virtue of the fact that no overhead system is necessary as a four-valve, portable, hermetically sealed transformer is standard with the apparatus.

Other features of our display will be certain accessories, such as Keraphen (the standard gall-bladder dye), Basolac (for gastrointestinal examination), Picker lead rubber gloves and Picker fluoroscopic goggles.

As one of the largest exclusive manufacturers of x ray apparatus, we are very happy to appear at the annual meeting of the Massachusetts Medical Society in the interest of x ray therapy and radiographic advancement.

- 27 and 35 John Wyeth and Brother, Incorporated, Philadelphia.

John Wyeth and Brother, Incorporated, will exhibit a number of their pharmaceutical specialties, including Silver Picrate, Council-accepted treatment for *Trichomonas vaginalis* vaginitis, Kaomagma, the intestinal adsorbent, Amphojel, Wyeth's alumina gel (antacid), and Ergoklonin, Wyeth's preparation of the alkaloid ergonovine, the specific oxytocic principle of ergot.

One of the points of interest at the booth will be a glass model of *Trichomonas vaginalis*, which has been exhibited at several medical meetings throughout the country. This model stands approximately ten inches tall, is of sufficient size in all the delicate inner structures so that this protozoon may be studied at leisure.

- 28 Form Publishing Company, New York City

The Collens System of Diet Writing is a loose leaf system containing the Collens Diet Calculator, an obesity chart, a diet formulary and one hundred menu prescriptions.

Book reviews have uniformly acclaimed it as the simplest, most ingenious and most practical contribution to the problem of diet writing for the physician. The calculator can be used for any diet requiring a quantitative consideration of carbohydrate, protein and fat, such as in diabetes, nephritis, nephrosis and epilepsy. The menu sheets are most practical for the patient.

See this ingenious system in the Form Publishing Company booth

- 29 Campbell X Ray Corporation, Boston

We shall exhibit the latest development in shock proof x ray apparatus and accessories

- 30 The Borden Company, New York City

New, yet already remarkably successful in infant feeding, Biolac is exhibited for the first time in Massachusetts at the Borden booth. Competent representatives will gladly provide specific, helpful information on the unique virtues of this modern, complete infant food.

Also exhibited are other Borden products, notably Dryco, Klim, Beta Lactose, Merrell-Soule Products and Borden's Irradiated Evaporated Milks.

- 31 Horlick's Malted Milk Corporation, Racine, Wisconsin

Nourishing, digestible, appetizing—these are three outstanding qualities for which Horlick's Malted Milk is famous, in either the powdered or tablet form. Visit Booth 31. You will be interested in the many dietary uses—from infant feeding to old age, note especially the convenience of the tablets for interval feeding in ulcer diets.

- 32 Sandoz Chemical Works, Incorporated, New York City

We will feature Digilanid, a chemically pure and constant preparation of the three isomorphous crystal line initial glucosides of *Digitalis lanata*, designated as lanatosids A, B and C, Digilanid tablets and liquid are available for oral dosage, suppositories for rectal administration, and stable ampule solutions for intramuscular and intravenous injection. Among other products displayed will be Bellergal, a pharmacodynamically balanced association of active neurotropic drugs, for the treatment of functional nervous disorders, neuroses and imbalances of the vegetative nervous system, Gynergen, the original and only product of the specific ergot alkaloid ergotamine, in pure and stable form for dependable uterine hemostasis and the non-narcotic relief of migraine, Calglucon, the pioneer brand of calcium gluconate in chocolate flavored tablets, effervescent tablets and granules for palatable oral calcium medication, as well as 10 and 20 per cent, stable, sterile ampule preparations of Neo-Calglucon for intensive parenteral calcium therapy, Scillaren, a brand of pure squill glucosides, a reliable cardiodiuretic.

- 33 Hynson, Westcott & Dunning, Incorporated, Baltimore

We shall have an exhibit featuring Mercurochrome and various pharmaceutical specialties of our manufacture. There will also be a display of some of the diagnostic apparatus and ampule solutions which have been developed in co-operation with physicians. As usual, competent representatives of the company will be in attendance to demonstrate the products and to answer questions. Literature and samples will be available to physicians who are not already familiar with products exhibited or who wish to obtain a trial supply.

- 34 Lee De Forest Laboratories, represented by the New England X Ray Corporation, Boston

Lee De Forest Laboratories are manufacturers and distributors of radio-frequency apparatus and feel that

- it is in their province to be principally concerned in the continued and persistent efforts to develop, for this new form of therapy and surgery, apparatus which carries a guarantee that can be relied upon and also a license under existing valid patents. After many months of exhaustive research in the field of radio-electronics, Lee De Forest now offers to the profession the 1937-1938 Dynatherms. Mr. George Laben and Mr. Dean Allen will be in charge of the exhibit.
- 36 Gerber Products Company, Fremont, Michigan
Gerber invites you to inspect its strained food, which will be on display. Two kinds of literature, some for professional use and some for distribution to mothers or adult patients on therapeutic diets, are both available for your examination and will be sent to you on request.
- 37 The Medical Protective Company, Wheaton, Illinois
The Medical Protective Company's representative, thoroughly trained in professional liability underwriting, invites you to visit Booth 37. He is entirely familiar with the principles of the reciprocal rights and duties of a doctor and patient and with the circumstances peculiar to that relation. He will be glad to explain how his company meets the exacting requirements of adequate liability protection, which are peculiar to the professional liability field.
- 38 The Denver Chemical Manufacturing Company, New York City
In Booth 38, Antiphlogistine will be exhibited. This product, now in its forty-fifth year, is employed by physicians in all parts of the world. It is a really universal product. Galatest will also be exhibited; this is a new microreagent for the instantaneous detection of urine sugar. Physicians are invited to visit the exhibit.
- 39 Talby-Nason Company, Boston.
The Giant Cod and photographs of the Lofoten Fisheries in Norway will be an interesting part of the exhibit of Nason's Palatable Cod Liver Oil. Mr. Robert Nason will be in charge.
- 40 Philip Morris & Company, Limited, Incorporated, New York City
Philip Morris & Company, Limited, Incorporated will demonstrate the method by which it was found that Philip Morris cigarettes, in which diethylene glycol is used as the hygroscopic agent, are less irritating than other cigarettes.
- 41 S. Israel's Correct Shoes, Incorporated, Boston
The value of S. Israel's Correct Shoes is recognized by the medical profession at large, and they are prescribed as a mechanical medicant in assisting the doctor in the banishment of the various bodily disturbances that are largely due to tarsus misplacement from faulty and incorrect footwear. These shoes are constructed of the finest materials obtainable on lasts that were developed by scientific measurements from feet in their individual classes and their various shapes and contours. They are assembled by expert craftsmen of a well-known shoe manufacturer, who is equipped to make shoes of this nature, and who has had fifty-five years' experience in making high-grade footwear.
- 42 White Laboratories, Incorporated, Newark, New Jersey
Information covering the cod liver oil field, together with clinical and biochemical evidence of the efficacy of the company's liquid, tablet and capsule forms of cod liver oil, will be presented by White Laboratories, Incorporated. Informed representatives and descriptive booklets, reprints and excerpts from the literature will further point out the contributions of White Laboratories, Incorporated, to the field of vitamins.
- 43 E. R. Squibb & Sons, New York City
Physicians attending the Massachusetts Medical Society meeting are cordially invited to visit the Squibb Exhibit in Booth 43.
The complete line of Squibb glandular, vitamin, arsenical and biological products and specialties, as well as a number of interesting new items, will be featured.
Well-informed Squibb representatives will be on hand to welcome you and to furnish any information desired on the products displayed.
- 44 The C. V. Mosby Company, St. Louis
Among the many books to be displayed by the C. V. Mosby Company are the second edition of Watson's *Hernia Reas Neuro-ophthalmology*, the fifth edition of Porter and Carter's *Management of the Sick Infant*, the fifth edition of Crossen's *Operative Gynecology*, and the sixth edition of Clendening's *Method of Treatment*. These recent releases will be supplemented by approximately one hundred seventy-five other texts.
- 45 The Coca-Cola Company, Atlanta, Georgia
The Coca-Cola Company in serving complimentary Coca-Cola at its booth hopes that "The Pause That Refreshes" will be enjoyed by guests and visitors of the meeting.
- 46 M & R Dietetic Laboratories, Incorporated, Columbus, Ohio
M & R Dietetic Laboratories, Incorporated, will display Simlac, a completely modified milk for infants deprived of breast feeding. Representatives will gladly explain its merit and suggested application.
- 47 Davies, Rose & Company, Limited, Boston.
The preparations that this firm is exhibiting have a world-wide reputation. Physiologic or chemical tests are made to insure their standardization. Clinical experience vouches for their dependability.
- 48 Petrolagar Laboratories, Incorporated, Chicago
Physicians are cordially invited to visit Booth 48 where Petrolagar Laboratories, Incorporated, will be represented by Messrs. Larson and Schneider.
Petrolagar is an emulsion of pure mineral oil (65 per cent by volume) and agar-agar, accepted by the Council on Pharmacy and Chemistry of the American Medical Association for the specialized treatment of constipation. Scientific drawings and literature on the subject of constipation will be available in addition to samples of the five types of Petrolagar.
- 49 Ernst Bischoff Company, Incorporated, Norvton, Connecticut
In our exhibit we will feature Actavin, the first American produced, shockless, foreign protein for non

specific therapy, Alpha Lobelin, a direct stimulant to the respiratory tract and the resuscitant indicated in all forms of respiratory failure or depression, Diatussin, the original drop-nose cough remedy with a thirty-five year record of efficacy, Silvogon, an absolutely stainless silver antiseptic, an effective gonocide, Styptysate, a vegetable hemostatic for the control of all seeping hemorrhages, Viscysate, a dialysate of viscum album which lowers blood pressure and relieves the accompanying symptoms

- 50 Westinghouse X Ray Company, Incorporated, Long Island City, New York.

The latest model Diadex Portable shown by the Westinghouse X Ray Company is an excellent example of the power and flexibility which modern engineering has built into today's compact, shock proof x ray equipment.

We also have on display the new Westinghouse Bactericidal Lamp

- 51 H J Heinz Company, Pittsburgh, Pennsylvania

In order that you may see the natural fresh color and uniform consistence of Heinz Strained Foods our display presents in an attractive manner all twelve varieties. Naturally, you have some questions as to their preparation and uses. We therefore invite you to let our representative serve you, in this respect.

We shall be glad to send you a copy of the fifth edition of our 'Nutritional Chart' upon registration at our exhibit.

ROUND TABLE CONFERENCE ON HIGHWAY FIRST AID

On Tuesday, May 31, at the time of the annual meeting of the Massachusetts Medical Society, there will be a meeting of the members of the Massachusetts Fracture Committee of the New England Regional Fracture Committee of the American College of Surgeons at the Hotel Bradford in the Lounge Ballroom from 3 to 5 p. m.

This Round Table Conference is for the purpose of hearing reports from various members as to the Highway First Aid Stations of the Red Cross in their districts and as to what has been accomplished, to date, as regards first aid equipment of ambulances and first aid instruction of ambulance drivers, local police, and so forth.

There are now fifty nine members on the Massachusetts committee, which was formed in November, 1936. Further organization of the group will be discussed in order that this committee may function more adequately and thus succeed in accomplishing the end for which it was formed.

There will be a few very short talks and the remainder of the session will be taken up by open discussion in which any member with constructive ideas is urged to take part.

A. WILLIAM REGGIO, M.D., *Chairman*
Massachusetts Fracture Committee

NEW ENGLAND ALUMNI— LUNCHEON MEETING

BALTIMORE MEDICAL COLLEGE, COLLEGE OF PHYSICIANS AND SURGEONS, UNIVERSITY OF MARYLAND MEDICAL SCHOOL

The annual luncheon meeting of the New England alumni will be held at the Hotel Statler, Wednesday, June 1, at 12 30 p. m.

CHARLES E. GILL, M.D., *Secretary*

MASSACHUSETTS MEDICO LEGAL SOCIETY

There will be a meeting of the Massachusetts Medico-Legal Society on Wednesday afternoon, June 1, in the Oval Room of the Hotel Bradford, at 2 30

PROGRAM

Business Meeting

Brief Presentation of Occupational Hygiene. Dr. Arthur B. Emmons, 2nd

Medico-Legal Aspects of Diabetes and Hyperinsulinism
Dr. Shields Warren

Dr. Timothy Leary, moderator, will receive and answer questions concerning puzzling points which occur to every medical examiner, and will also interpret the laws

NATHANIEL POPE BREED, M.D.,
President,

MYRTLE M. CANAVAN, M.D.,
Secretary-Treasurer

HARVARD MEDICAL ALUMNI ASSOCIATION

The luncheon and annual meeting of the Harvard Medical Alumni Association will be held at the Hotel Bradford, on Tuesday, May 31, at 12 30 p. m. The meeting preceding the luncheon will be brief. Dean Burwell will speak.

Tickets for the luncheon will be on sale at the Registration Desk, the charge being \$1 00

TUFTS MEDICAL ALUMNI LUNCHEON

A buffet luncheon for the alumni and friends of Tufts College Medical School will be held on Tuesday, May 31, at 12 15 p. m. at the Hotel Bradford.

Those planning to attend should communicate with the secretary, Dr. Robert T. Phillips, 386 Commonwealth Avenue, Boston

OBITUARY AND RESOLUTIONS

FREDERIC JAY COTTON

1869-1938

The Massachusetts Medical Society has recently lost one of its most distinguished members, Dr. Frederic Jay Cotton.

Born in Prescott, Wisconsin, son of Joseph Potter and Isabella Cole Cotton, Dr. Cotton was educated at Harvard College (A.B., 1890, and A.M., 1894) and Harvard Medical School (M.D., 1894). He became a surgical intern at the Massachusetts General Hospital and then studied in Vienna and visited various European clinics for two years.

He was next appointed a visiting surgeon at the Boston City Hospital. Dr. Cotton advanced through various grades of rank, eventually becoming senior surgeon-in-chief and chairman of the Surgical Staff, and subsequently, consulting surgeon, in which position he served faithfully and well for many years. At one time he was surgeon-in-chief at the Beth Israel Hospital and was a teacher of surgery at both Harvard Medical School and Tufts College Medical School. For some time

he was a visiting surgeon at the Children's Hospital

Dr Cotton practiced general surgery in his early years but later became interested in fractures, bone and joint surgery, and industrial and plastic surgery. His many valuable contributions to medical literature in these fields of surgery are a monument to his skill and ingenuity. His textbook on *Fractures and Dislocations* has been used throughout the country as a standard by countless students and members of the profession, he drew practically all the illustrations in this book. His own vast experience and progressive views derived from an extensive practice were ably expressed in his writings.

He established the Bone and Joint Service at the Boston City Hospital, becoming the first surgeon-in-chief of the Sixth Surgical Service. At this time he limited his operating to bone and joint cases exclusively, and for many years personally followed up his patients in the Outpatient Department.

Doctor Cotton was particularly interested in hip fractures, and he was one of the first surgeons to abduct the leg and artificially impact the broken hip. Cotton's fracture of the ankle was ably described by him many years ago, and his classification of ankle fractures has been widely accepted. Many years ago his advanced ideas permitted him to evacuate infected joints and suture them without drainage, which was an unheard-of procedure at that time.

He originated many novel methods of operating, and was one of the first surgeons in the country to recognize the disabling character of fractures of the wrist and of the os calcis and to devise methods for their correction. Acute flexion position for elbow injuries and internal fixation for fractures were early advocated by him. He was a pioneer in creating modern gas-oxygen machines for anesthesia, in conjunction with Dr Boothby. The modern Gwathmey and Foregger machines are patterned after Dr Cotton's ideas.

Doctor Cotton served his country with distinction in the Spanish War and in the World War, being commissioned a major in the Medical Corps, United States Army. He was appointed surgeon-in-chief of the Walter Reed Hospital and subsequently acted in the same capacity in Boston at the Elks Reconstruction Hospital. He was also an assistant and a valued adviser to the Surgeon-General.

As a founder and member of the Board of Regents of the American College of Surgeons and of the American Board of Surgery, Doctor Cotton exerted a great amount of influence in raising the standards of surgery and of hospitals in America. He was also a senior member of the Ameri-

can Surgical Association and of the American Orthopedic Association.

His versatility was shown by his excellent work in sculpture, etching, and water-color and oil painting. He was a charter member of the Boston Physicians' Art Society and arranged their annual exhibits.

His widow, Jane Baldwin Cotton, and a daughter survive him, as well as two grandchildren.

Doctor Cotton endeared himself to his countless patients and associates because of his unfailing good nature and his kindly advice and generous help to those in trouble. He was always willing to lend a helping hand and to give invaluable advice to the younger generation.

Of powerful build, impressive appearance and commanding personality, Doctor Cotton combined many rare qualities which resulted in making him a skillful and successful surgeon of national reputation.

W R M

RESOLUTIONS ON THE DEATH OF BENJAMIN WHITE

WHEREAS, Dr Benjamin White was an active member of the Association for thirteen years (1921 to 1934), and

WHEREAS, in recognition of his services, he was made an honorary member of this Association when ill-health necessitated limitation of his activities, and

WHEREAS, his industry and zeal in promoting the public health of Massachusetts not only by his direction of the preparation of biologic products but also through his interest in the extension of programs for active immunization against small-pox and against diphtheria and through the initiation of a plan for the study of pneumonia and its control led to strengthening and improving public-health work in this Commonwealth, therefore be it

RESOLVED, by this Association, assembled in regular meeting, that it records in its minutes its sense of regret in the loss to the Association and to the advancement of the public health occasioned by the death of its distinguished member and be it further

RESOLVED, that copies of this resolution be transmitted to the appropriate journals for publication, and to his widow to whom the Association extends its deep sympathy.

Unanimously adopted by a rising vote at a meeting of the Massachusetts Public Health Association held April 27, 1938.

G DONALD BUCKNER

Boston

CASE HISTORY No 72 BLEEDING IN THE TWENTY-
EIGHTH WEEK OF PREGNANCY

Mrs J W, twenty-four years old, in the twenty-eighth week of her first pregnancy, passed, without any pain, what she estimated as a quarter of a cup of bright-red blood and a small clot. She was sent at once to the hospital.

Her family history was unimportant. In childhood, she had had a hemolytic streptococcus throat. In 1927 her tonsils and adenoids were removed. In July, 1935, a dilatation and curettage, plastic on the cervix, suspension and appendectomy were performed. Catamenia began at fourteen, were regular every twenty-eight days, and lasted four or five days. She had had severe cramps until the operation in 1935. Her last period began October 23, 1935, making her due for delivery July 30, 1936.

She was first seen December 17, at which time the lungs were clear, there were no rales, the heart showed no enlargement and there were no murmurs. Her blood pressure was 122 systolic, 70 diastolic. The urine contained no albumin or sugar. Abdominal examination was negative except for a median scar below the umbilicus. Vaginal examination showed a marital introitus, the cervix was soft and smooth, and the uterus in normal position, definitely a little large and globular. The vaults were free, and there was no erosion of the cervix. Her pelvic measurements were 30-24-20, the symphysis and arch were normal, and the outlet ample. She was seen routinely during her pregnancy which progressed satisfactorily and normally until the above-mentioned bleeding on May 10.

On arrival at the hospital her blood pressure was 118 systolic, 66 diastolic. The urine specimen contained no albumin or sugar. The fundus measured 27 cm above the symphysis. The fetal heart was heard in the right lower quadrant. By palpation the vertex was presenting above the brim. Her red-cell count was 3,650,000, white-cell count 11,200, and the hemoglobin 69 per cent. The patient's blood was typed and found to be incompatible with that of her husband. She was not flowing on admission to the hospital, and no vaginal examination was made. The diagnosis lay

between separation of a low-attached placenta, slight separation of a normally attached placenta, or some type of placenta previa. As the baby had a less than 50 per cent chance of survival if delivered and the patient was able to stay in the hospital until the baby was viable, it was decided to follow this course. There was no flowing after the time of her admission.

On June 11 a cystogram was taken after the injection of 40 cc of a 3 per cent solution of sodium iodide into the bladder. The x-ray plate showed the fetus presenting by the face, probably a posterior face, the distance between the bladder and the head was 18 mm. On the right side and in the central portion of the bladder outline there were two levels of density indicating that portions of the center and right side of this area were occupied by an unusual soft-tissue mass. An x-ray diagnosis was made of partial placenta previa on the left with brow presentation. On June 27 the patient was examined vaginally. Everything was in readiness for the insertion of a bag or a cesarean section. Vaginal examination showed that the head was down against the cervix and that apparently nothing was in front of it. The cervix was short and easily admitted one finger. A finger was passed through the cervix and came directly against the vertex. The finger was swept around for a distance of 5 cm above the internal os and no placenta was felt. This examination ruled out any type of placenta previa. As a result of this examination she started in labor very soon. All through that day she had definite contractions lasting from three to five minutes, but there was no show, and not much discomfort. At 4 00 p m a rectal examination showed the cervix to be short, about one and a half fingers dilated, and the head down against it. The membranes ruptured spontaneously at 9 00 p m, after which the pains became harder and occurred every three minutes. She had a normal labor which terminated at 1 14 the next morning with the delivery of a male child, weighing 6 lb, 7 oz., in excellent condition. There was a small median tear which was repaired. The placenta separated and was expressed intact with membranes complete. The placenta showed evidence of an old partial separation, the membranes had ruptured 15 cm from the edge of the placenta. There was no unusual bleeding, and both mother and baby were in excellent condition.

Comment The conservative handling of cases that bleed at a period when viability is very questionable and when the bleeding entirely ceases is well illustrated by this particular case. If an examination had been made and the finger put through the cervix for the purpose of making

an absolutely definite diagnosis and if a central placenta previa had been present, bleeding might have been so great that immediate delivery would have been indicated, if such were the case, the chance of obtaining a living child would have been small. If this patient had bled again while she was in the hospital, then an examination would have been imperative so that an exact diagnosis upon which intelligent treatment might be instituted, could be made. A patient at this stage who bleeds painlessly, may bleed from the separation of a normally situated placenta, a low-attached placenta or placenta previa of any one of the three types. Cystograms have been used for the last few years for the purpose of making a diagnosis of placenta previa. In this instance the x-ray diagnosis was definitely wrong. This patient was treated ideally and a perfect result was obtained.

THE PRE-SCHOOL CHILD

In these modern times it is a little difficult to define exactly the pre school stage of life, when so many children arrive at the nursery school door practically dragging their cradles with them. The social, if not the legal, term of infancy is construed as occupying the first two years of life, with children of three seeking and gaining admission to the nursery schools in rapidly increasing numbers. It would appear that the period of life concerning which we are to talk frequently consists of but a year in the life of the individual.

It may be just as well, however, since this is the period of the child's life that has long been termed "The Neglected Age," that it should be made as short as possible. The very fact that it is being shortened shows that we have become conscious of its needs.

During the infancy of the child its most urgent demands are physical ones. It protests when it is uncomfortable, hungry or in pain. It makes its wants felt and they are attended to. We are in danger of forgetting the fact that an infant has more needs than a stomach to be filled and a diaper to be changed, that its mind requires, from its earliest months, lessons in adapting itself to the environment in which the individual must live.

When pre school days are reached, when the quadruped infant becomes the biped runabout child, the necessity of training him forces itself upon us. Originally in danger of regarding the infant as a body without a mind, we now run the risk of regarding the pre school child as a mind without a body—an equally serious error.

Actually, at every age of childhood our obligation as parents, as teachers as nurses or as physicians is to try and maintain a just balance between those mutually reciprocal parts of the human entity—the mind and the body.

Various necessities present themselves to us in this period of rapid development of the child—the period from two to five or six, to accept the more orthodox school age. We are in danger now of neglecting the diet, which had been so carefully overseen during the child's infancy, not only in allowing unsuitable foods, but in failing to include principles necessary for healthy growth. We are a nation of carbohydrate eaters, and our appetite for this

class of foods—the starches and sugars—makes us liable to neglect the foods that contain in greatest abundance the necessary minerals and vitamins, that is, the fruits, the vegetables, milk and eggs.

A minimum basic diet for a growing child consists or at least a pint of milk a day, one or more cooked vegetables, a raw fruit or vegetable or both, eight ounces of some fruit juice, an egg or meat or fish, and some source of vitamin D, such as cod liver oil, at least during the winter and spring months. These basic requirements having been fulfilled, other foods such as the cereals, the breads, desserts, and so forth, may be used to satisfy the appetite and make up the energy requirements of the body.

I mentioned at least a pint of milk a day as a fundamental part of our basic diet. Children with normal, healthy appetites may drink as much as a quart, but I consider that the slogan "A quart of milk a day" has done considerable harm. Many children cannot take this amount of milk in a day without seriously interfering with their appetites for the other essential parts of the diet, and loss of appetite constitutes one of the major problems in dealing with many children of today.

This appetite problem must be met by reducing the quantity of milk, if milk is a food of choice, by stopping all eating between meals, by giving a well-balanced diet in small servings, but as attractively as possible, by limiting the time allowed for eating and by letting the child see plainly that his or her eating habits do not cause anyone any concern. This method of approach, however, is not tried for a day, a week or a month. It is an attitude that must be maintained permanently.

There is considerable evidence available that a sound basic diet is also a heavy contributor to the campaign for sound, healthy teeth, something in which civilized races are sadly lacking. Watch your child's six-year molars, the first of the permanent teeth that come in near the end of or soon after our pre school period. Those cavities to which they are so susceptible may be partly the result of a lack of orange juice, of milk or of cod liver oil during the years before their appearance.

Do you keep a dish of candy on the sideboard or the living room table? Perhaps this is responsible for that dental decay of his that you deplore so much, or have not even noticed, if toothache has not yet set in. Candy is permissible, yes, but only of very simple types and only after a meal that has been satisfactorily eaten.

The question of filling the cavities that have occurred in the temporary teeth is sometimes debated. Certainly there can be no reason for neglecting teeth that must serve a child during the ten or twelve years when his jaws are taking on their final shape and his life's health is in the making.

Many children will have been vaccinated against small pox and immunized against diphtheria during their first year of life, and that is the best age in which to have those immunizations performed. If they were neglected during infancy, however, they should be performed early in the pre school years, for universal immunization is a small price to pay for the practical banishment of two dread diseases. Immunization against other diseases such as whooping cough and scarlet fever may be attempted in individual instances, but is not yet being universally applied.

Those acute infectious diseases for which we have no effective immunization must, however, be guarded against by protecting our children, so far as possible, from exposure to them. The common cold in itself causes a great

A "Green Lights to Health" broadcast given by Dr. Joseph Garland on Wednesday May 4 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

er loss of time from useful activity than does any other disease, and in childhood particularly, may be the apparent forerunner of many of the more serious illnesses. While the activity of the pre school child may not be considered as useful from the economic standpoint, we nevertheless do not like to see him deprived of it for even a short time because of preventable sickness.

While we are on the subject of acute infections, it is well to bear in mind that removal of the tonsils, particularly during the early years of life, does not open the gateway to perpetual health, nor does it necessarily prevent the further occurrence of common colds, swollen glands or fallen arches. The removal of tonsils should be considered as a major operation, to be accepted only on the merits of the individual case as the result of a decision carefully rendered.

Aside from the acute infections, one of the major enemies of early childhood is chronic fatigue, and as a result of chronic fatigue we are very likely to find poor body mechanics. The sway-backed, soft muscled, flat-chested, round shouldered child with protuberant abdomen and flat feet is almost surely a victim of chronic fatigue, and his faulty posture may be a contributory factor to his fatigue.

We live in an age of speed, pressure, anxiety and almost constant emotional stimulation, and our children need protection from it. Instead we allow them to abandon their daily rests at too early an age, to stay up too late at night and to seek overstimulating forms of amusement. The result is chronic fatigue and emotional instability, both of which seriously interfere with our efforts to cultivate their bodies, train their minds and help them to establish self-control.

I would recall to your minds the first two provisions of the Children's Charter, adopted as a bill of rights for the child at the White House Conference of 1930.

1 For every child spiritual and moral training to help him stand firm under the pressure of life.

2 For every child understanding and the guarding of his personality as his most precious right.

There is no assurance in these troublous days that we can hand down to our children very much in the way of tangible securities or concrete goods. We can, however, give them certain things that cannot easily be taken from them—good habits, self reliance, self respect, a security in right thinking and right living that in later life may help them to stand firm while their world seems to be falling about them. We would have them believe, like the old character in Hugh Walpole's *Fortitude* that it isn't life that counts, it's the courage you bring to it.

To do these things we must give them homes in which they can have a sense of spiritual as well as of economic security, we must teach them emotional stability by example rather than by precept, we must recognize the fact that social adjustment begins not in the school but in the cradle.

* * *

Q How much rest does a child of four require?

A The child of four years requires about twelve hours of sleep, or a little more, which means more than this length of time in bed. An interesting study made a few years ago by the University of Minnesota Institute of Child Welfare showed that more sleep is taken in the winter than in the summer, and that country children take less than city children. The length of night sleep from the age of two years through the age of seven remains practically stationary at eleven hours, so that the diminution in total sleep beyond the age of two is accounted for largely by the shortening and gradual abandonment of the nap. However, a midday rest, even if no sleep is taken, should be continued at least through the pre school years.

Q On what basis should a decision for or against the removal of tonsils be made?

A This is frequently a difficult question to decide, and yet it is one that comes up at least once in the lives of most children. I am hopeful that we are becoming increasingly more conservative in recommending the operation. Very little help can be gained by actually inspecting the tonsils. What is of greatest importance is the past health record of the child, particularly as regards frequent attacks of sore throat or tonsillitis, frequent ear abscesses or infection of the glands in the neck. Head colds cannot be prevented by tonsillectomy, but to a certain degree their complications may be. Thus, although children without tonsils may still have ear abscesses, sinus infection and gland infections, their chances of having them are somewhat reduced after tonsillectomy, provided that they had previously been particularly susceptible to them.

Favorable results from tonsil and adenoid removal seem to last about three years, after that period of time the benefits tend to disappear. Even where the operation seems to be necessary, it is well to delay it, if possible, until after the age of five or six.

Q Do you approve of nursery schools?

A Yes, on the whole I can say that I do approve of nursery schools, although the answer deserves to be guarded. Three factors are involved, the school, the child and the home. Enthusiasm alone cannot make a good school. Combined with it must be an understanding of the obligations involved and the duties to be performed. Such a school can be of service to a child who has no natural playmates or whose home environment needs to be supplemented. Naturally, no school can replace the home.

DEATHS

McMURRAY—FRANCIS M. McMURRAY, M.D., of 101 Prichard Street, Fitchburg, died at his home, May 8. He was in his sixty sixth year.

Born in Merrimack, he attended the Fitchburg High School, graduated from Brown University and received his degree from the New York University College of Medicine in 1899.

Before beginning practice in Fitchburg, in 1899, he was a reporter for the *Fitchburg Mail* and the *Fitchburg Sentinel*. For several years he was city physician and at the close of the last century was clerk of the city's common council. Dr. McMurray was president of the staff at the Burbank Hospital for many years and had been chief anesthetist at the hospital for several years. He was a fellow of the American Medical Association and the Massachusetts Medical Society, past president of the Worcester North District Medical Society and its secretary at the time of his death.

His widow, a daughter and a brother survive him.

WHEELER—CHARLES D. WHEELER, M.D., of Worcester, died May 7. He was in his seventy third year.

Born in Worcester he prepared for college under private tutors in Marblehead, and graduated from Williams College and from the Harvard Medical School. In 1893 he began practice in Worcester. In 1906 he became associated with the State Mutual Life Assurance Company as medical examiner and rose to the position of medical director, a position he held at the time of his death. He was at one time consulting surgeon at Worcester City Hospital, and served on the Federal Advisory Board during the World War.

Dr. Wheeler was a fellow of the American Medical As-

sociation, the Massachusetts Medical Society, the Worcester District Medical Society and the American College of Surgeons. He held memberships in the Worcester Club, the Worcester Chamber of Commerce and the Williams Club of New York City and was also a member of the Masonic Order.

His widow, a daughter, a son and a granddaughter survive him.

WINN—CHARLES H. WINN, M.D., of 808 Commonwealth Avenue, Newton Centre, died May 10. He was in his seventy-fifth year.

A native of Boston, he attended the Boston public schools, later graduating from Boston College and receiving his degree from the Harvard Medical School in 1888.

The first medical examiner ever appointed by the Aetna Life Insurance Company, he served fifteen years in that capacity. He was also medical examiner for the Boston Elevated Company. For ten years he was visiting surgeon at St. Elizabeth's Hospital and was appointed by President Cleveland to the United States Board of Examining Surgeons for Pensions.

Dr. Winn was a member of the American Medical Association and a fellow of the Massachusetts Medical Society.

Two daughters, a son and a sister survive him.

YOUNG—WILLIAM B. YOUNG, M.D., of 86 Fresh Pond Parkway, Cambridge, died May 11. He was in his fiftieth year.

Born in Rockland, he attended the Rockland High School, graduated from Harvard University and received his degree from the Harvard Medical School in 1918.

Dr. Young was a former resident surgeon at the Haymarket and East Boston relief stations. During the World War he was a captain in the medical corps and later became resident surgeon of the Boston City Hospital and visiting surgeon of the Boston Lying-in Hospital. He subsequently joined the staffs of the Cambridge Hospital and Cambridge City Hospital, which posts he held at the time of his death. For many years he was an instructor in the Department of Obstetrics, Harvard Medical School.

A fellow of the Massachusetts Medical Society, he was also a member of the American Medical Association.

His widow, a daughter, four brothers and two sisters survive him.

MISCELLANY

DIFFICULTIES IN DEALING WITH THE TUBERCULOSIS PROBLEM

DIFFICULTIES ENCOUNTERED IN INDUSTRY

According to Lane (*Tubercle* 19:97-104, 1937), enlightened industry nowadays realizes that it must carry a certain number of subnormal individuals. In the long run this is sound economic policy, for industry cannot afford to lose trained employees or to breed psychological unrest of workers caused by the knowledge that loss of employment will follow serious or prolonged illness. Yet the employment of workers who have tuberculosis, or have recovered from the disease, is an exceedingly awkward problem, for tuberculosis is insidious and infectious and leaves its sufferers incapable of normal physical effort for long periods.

Economic difficulties experienced by the tuberculous wage earner are serious. They are partially relieved by

continuing part wages. Treatment in the sanatorium is rendered easier and more effective if the worker is relieved of immediate worry and is given hope for the future. It reduces the temptation to return to work too soon.

Environmental difficulties are particularly acute in working-class areas. The problems of slums, overcrowding and undernourishment are being solved by the slow social evolution now going on.

Difficulties arising out of the patient's own attitude include (a) fear of losing his income, (b) fear of losing his job, and (c) fear of the sanatorium. These fears can be greatly allayed if the policy of the firm is to take back employees when they have recovered. The dread of the sanatorium can usually be overcome by education and wise propaganda.

The difficulty of returning to a different kind of work than that to which they have been accustomed must be faced by some workers. A man must know that his job is a real one and not one created merely to find him employment.

The employer's difficulties must be faced squarely. The returning tuberculous patient has usually a greatly reduced efficiency. He is inferior to the normal worker and this inferiority is likely to persist for a few years. If he attempts to keep pace with fellow workmen he invites early breakdown. Industry quite naturally is not likely to welcome the worker who needs a sheltered life if he is a new entrant, but most employers will take back old employees if the prospect of eventual return to reasonably good health exists. Of course, industry has to deal with many employees disabled by conditions other than tuberculosis. With these crocks the returning tuberculous worker has to compete for the suitable job. Many are the employer's problems in adapting the needs of industry to the employee who cannot be subjected to strains such as overtime work, shift and night work, and competition with more vigorous workers.

It is, of course, not possible to pay higher wages to the tuberculous patient than to other workers. In fact he must often be satisfied with a lesser wage. This means that at the very time he needs a higher and better standard of living, he actually has to be content with a much lower one. This situation calls for generous co-operation between the employer and the Care Committee (well organized in England). The tuberculous patient returning to industry should be subsidized until he is able to earn a reasonable wage. Industry cannot be expected to make the subsidy directly.

The danger of infecting other employees must also receive attention. A patient with a positive sputum should not be allowed to return to surroundings where he may infect others. Certainly he should not be permitted to engage in industry involving the handling or packing of food or which requires him to come into contact with the public.

The author urges close liaison between the tuberculosis service and industry. Small firms find it particularly difficult to deal with recovered tuberculous patients but can do much if the facts about tuberculosis are carefully explained to them by the medical officer or doctor. The doctor must not only be conversant with the disease but must also possess an intimate knowledge of the industry and requirements of the workers if he is to talk reasonably and convincingly with the management.

DIFFICULTIES OF THE SUPERINTENDENT OF A MENTAL HOSPITAL

According to Cormac (*Tubercle* 19:107-113, 1937), the records of Parkside Mental Hospital show that in the

past 30 years, 340 deaths occurred in which tuberculosis was a factor. Of these, 80 per cent were sufferers from some form of dementia or a depressed state, or were imbeciles or idiots. Patients suffering from these forms of mental disorder are usually incapable of complaining of feeling ill. They are lethargic and disinclined to take exercise, indifferent to food and of degraded habits. Respiration is shallow and infrequent and circulation is poor.

The diagnosis at an early stage is not easy as the usual physical signs are not apparent. It is necessary, therefore, to record the weight weekly, to take the temperature daily, to examine regularly the feces for the presence of tubercle bacilli and to use the x-ray when indicated.

The pressure of economy weighing on public institutions leads to difficulties of providing segregation, overcrowding, poor dietary, absence of laboratory facilities, inadequate milk supply and an insufficiently trained nursing staff.

These and other difficulties, common to most mental hospitals, have been largely overcome at Parkside Mental Hospital since the appointment of the present medical superintendent in 1914. The ratio of deaths from tuberculosis at Parkside compared with (English) county and borough mental hospitals has been decidedly lowered. In 1935, for example, this ratio for Parkside was 15 deaths from tuberculosis per 1000 patients in residence as against 46 in all other hospitals.

DIFFICULTIES OF THE GENERAL PRACTITIONER

According to Jackson (*Tubercle* 19 114 117, 1937), to persuade people, especially young people, to submit to observation and treatment during what might be called the "antenatal" stage of the disease in which no certain diagnosis can be made in the face of the doctor's suspicion, is a problem of the general practitioner. The chief reasons for the reluctance of patients to seek medical aid include

- 1 The temporary improvement in their general health following treatment which lulls both the patient and the doctor into a false sense of security.
- 2 Prejudice against being regarded as a subject for notification. Patients fear the social stigma, segregation and threatened invasion of their homes by the authorities.
- 3 Alarm caused by the prospect of losing income. This is probably the greatest obstacle to continued observation. The vast majority of working-class people simply cannot afford to be ill and hesitate to seek an opinion which will run counter to their own inclinations.

Other difficulties include the isolation of the patient at home, the supervision of contacts, and the question of fitness for work. The doctor's greatest difficulties are the social environment and low standards of living of his patients. — (Reprinted from *Tuberculosis Abstracts* May, 1938.)

SYPHILIS CONTROL AND TUBERCULOSIS CONTROL HEALTH CONTEST

This year as a part of the City Health Conservation Contest conducted annually by the Chamber of Commerce of the United States in co-operation with the American Public Health Association awards are being made for the most effective community wide programs for syphilis and tuberculosis control.

The committee of health experts known as the Grading Committee recently announced the following winners in the Syphilis Control Contest

First award goes to Tacoma, Washington, with awards of merit going to Hartford, Connecticut, Newark, New Jersey, Louisville, Kentucky, and New Haven, Connecticut.

In the Tuberculosis Control Contest, the winner is Detroit, Michigan, with awards of merit going to Newton, Massachusetts, Hartford, Connecticut, and New Haven, Connecticut.

A few of the items considered by the committee were the comprehensiveness of case finding and follow up services in connection with tuberculosis and syphilis, the facilities provided for diagnostic and treatment purposes, the extent of group participation in programs of education and control.

NEW UNIT AT THE MASSACHUSETTS GENERAL HOSPITAL

The contract for the construction of the George Robert White Memorial Building at the Massachusetts General Hospital has recently been awarded. This new unit, which will cost \$2,500,000, will be located directly back of the automobile entrance on Fruit Street and will replace several obsolete buildings. It will stand thirteen stories high and is designed to conform architecturally with the other buildings of the hospital. About a year and a half will be required for its completion.

The lower five floors will be occupied by departments that serve all divisions of the hospital, and the upper floors will contain operating rooms and surgical wards. The Bulfinch Building will be remodeled to house all the medical patients and laboratories.

NOTES

The University of Oxford has conferred the degree of doctor of science on Dr. Harvey Cushing, Moseley Professor of Surgery (emeritus), Harvard University, and Sterling Professor of Neurology (emeritus), Yale University.

Dr. S. Burt Wolbach, Shattuck Professor of Pathological Anatomy, Harvard University, was elected a member of the National Academy of Sciences at its recent annual meeting.

Dr. Barbara Ring of the Ring Sanatorium and Hospital in Arlington was recently awarded the Order of Merit by the Chilean Government for furthering inter American friendship. The presentation took place at the Chilean Embassy at Washington, and was occasioned by Dr. Ring's play "O Higgins of Chile."

At the recent annual meeting of the American Association in Mental Deficiency, held in Richmond, Virginia, Dr. Neil A. Dayton, director of the Division of Mental Deficiency and of the Division of Statistics and Research, Massachusetts Department of Mental Diseases, was elected president.

Middlesex University has recently announced the following full time appointments to the faculty of its School of Medicine: Dr. David L. Davidson, Sc.B. in Chemistry (summa cum laude), Sc.M., and Ph.D. in Biology, Brown University, to the Department of Biochemistry; Dr. Nathan R. Brewer, B.S., D.V.M., Michigan State, Ph.D. in Physiology, University of Chicago, to the Department of Physiology; and Dr. Rainer Zangerl, Ph.D., University of Zurich, to the Department of Histology.

CORRESPONDENCE

A CORRECTION

To the Editor I request that the *New England Journal of Medicine* correct the statement which appeared in the issue of May 5, to the effect that I stressed the need for more free and part pay evening clinics at the annual meeting of the Hospital Council of Boston on April 26 1938, by publishing in full the following statement made at that meeting in regard to this matter

Evening Clinics At the request of the Boston Council of Social Agencies, the Executive Committee of the Hospital Council appointed a committee to determine whether evening clinics beyond those now existing were needed in Boston. The committee sent a letter to forty four health and social agencies and twenty three hospitals, asking whether, in their opinion, people were deprived of adequate medical care because of lack of free or part pay evening clinics and whether in their opinion people were paying full evening clinic rates who ought to have the service free or at part cost rather than at full rates. Fifteen replied there was no need for further facilities, four were uncertain and fifteen felt there was need for further evening clinics. The committee, in reviewing the replies, felt that the majority of the group questioned was of the opinion that more evening service was needed, although actual supporting data are rather meager.

The Boston Dispensary reported the Monday and Friday evening clinics were being crowded and it was considering re-opening Wednesday evening. The Massachusetts Memorial Hospitals felt that their clinic was too crowded and were contemplating a second evening. These clinics were opened later.

The Committee to Study the Need for Evening Clinics, therefore, recommended that, if these two additional services were established, consideration of the extension of further evening clinic facilities be deferred until it is determined whether this extension is sufficient. The committee also recommended that if this extension of the existing evening facilities proves inadequate for the demand of free and part pay evening clinic service, the advice of the Massachusetts Medical Society be sought before further evening clinics are established under the auspices of the Community Federation of Boston.

BOOK REVIEWS

Apoplexies Viscérales Sereuses et Hemorragiques (Infarctus Visceraux) Raymond Gregoire et Roger Couvellaire. 178 pp Paris Masson et Cie, 1937 50 Fr fr

This is a well-organized book in which the authors present experimental and clinical data to support their concept that so-called visceral apoplexy results from anaphylactic shock. They distinguish apoplexy from infarction, in that infarction involves a gross lesion of the vessels, whereas apoplexy does not. Infarction causes the death of a part, whereas apoplexy does not necessarily do so.

The authors emphasize that such apparently diverse conditions as hemorrhagic pancreatitis, so-called intestinal infarction without a gross vascular lesion, so-called thrombosis of the uterus and tubes, thrombosis of the testicles, pulmonary apoplexy and cerebral hemorrhage have certain characteristics common to all. They occur suddenly and the most striking general symptom is the precipitate fall in arterial tension. Certain characteristic changes occur in the various organs involved, and the authors believe that the individual variations depend upon the anatomy and function of the particular organ which is attacked.

They believe that they have been able to reproduce the general and local characteristics of the above mentioned conditions in experimental animals. Briefly, their experimental work has consisted of producing anaphylactic shock in such animals as the dog, rabbit and guinea pig

By sensitizing an organ to a foreign protein and later producing a generalized shock, they were able to reproduce the picture of hemorrhagic pancreatitis and the so-called infarction or thrombosis of either the intestine, uterus, testicles or lung. They discuss the mechanism of anaphylactic and anaphylactoid reactions and emphasize that it is a disturbance of the endothelium of the vessels, or more accurately, the result of a stimulation of the vegetative nervous system which runs in the endothelium. There is a vasodilation of the capillaries and venules severe enough to arrest or stop the flow of blood.

Surgery cannot be of much use in treating such a condition, and therapy should be directed toward limiting the general shock manifestations and combating the vasodilation existing in the involved organ. A general anesthetic is useful in decreasing a generalized disturbance of the vegetative nervous system, and the benefit which surgery seems to give to some of these cases may come from the anesthetic. Drugs such as adrenalin may be used in an attempt to overcome the local vasodilation.

The subject matter in this book is well arranged. The authors give their experimental results in considerable detail. Anyone interested in this subject should read the book.

The Laboratory Diagnosis of Syphilis The theory, technique and clinical interpretation of the Wassermann and flocculation tests with serum and spinal fluid Harry Eagle 440 pp St. Louis The C V Mosby Company, 1937 \$5.00

The author takes up in great detail in the first eight chapters the Wassermann test in its various steps from a laboratory technician's point of view. In the next four chapters he deals with the various flocculation tests from the same point of view. There are two chapters on procedures with spinal fluids and one on tests other than Wassermann or flocculation tests.

For the clinician, the successive chapters discuss the clinical evaluation and the statistical comparison of these various tests.

This book should be of great value both to the laboratory worker and the clinician and should be in a library and wherever tests are being made or syphilis is being treated. The bibliography is exhaustive.

Theoretical Principles of Roentgen Therapy Edited by Ernst A. Pohle. 271 pp Philadelphia Lea & Febiger, 1938 \$4.50

As the name implies, this volume is devoted chiefly to the physics of roentgen rays. In addition, there are some remarks on the biologic effects of radiation.

The first chapter is contributed by K. W. Stenstrom, Ph.D., it deals briefly with nuclear physics and the production, characteristics and measurement of roentgen rays. The second is by Dr. R. R. Newell, and is devoted to a description of various types of x-ray apparatus. The third, by L. S. Taylor, Ph.D., and Dr. E. A. Pohle, deals with practical dosimetry. Dr. F. C. Wood has contributed the fourth chapter, which concerns radiobiology and radiopathology. Dr. L. S. Taylor concludes the volume with a consideration of protection from roentgen rays.

The book is interestingly written and is designed for the radiotherapist who desires a thorough understanding of the theoretical principles underlying roentgen ray therapy. The need for such a work has long been felt and has been admirably met.

NUMBER 21

THE GROWTH OF THE BOSTON CITY HOSPITAL FROM 1864 TO THE PRESENT

MERRILL MOORE, M.D. *

BOSTON

SEVENTY-FOUR years ago the citizens of Boston started something new in community ventures. They built a public hospital, "designed in the words of the first annual report of its trustees, "to do the greatest possible good to the greatest possible number."

The traditional span of a man's life having passed it seems timely to try to analyze and suggest, on a statistical basis, how well the Boston City Hospital has succeeded in living up to the high purposes and hopes of its founders.

Because figures are notoriously cold, it is impossible by the geometry of a statistical curve to estimate pain allayed and suffering made supportable. But a little thought will enable any mind to penetrate through the impersonal figures recorded here and to perceive the human values they represent. In the gradual but steady expansion and improvement of the Boston City Hospital eloquent proof is offered that the founders' aim, while always falling short of perfect fulfillment, is still the activating ideal of the hospital and the inspiration of its staff.

From the present complicated institution with its multiplicity of departments and services and clinics and offices, it seems a far cry back to the unpretentious beginnings of 1864. Yet in these years the hospital has treated more than a million patients. The demand for its services has grown so much that while Boston ranks ninth in population in the United States, the Boston City Hospital ranks sixth in size and fourth in the number of patients treated. From 1864 to the present, while the population of the city has increased four and a half times, the hospital admissions have increased over forty times (Chart 1). And since the average daily number of patients has skyrocketed the absolute number of deaths has naturally in-

creased, although the relative mortality has been definitely lowered.

Reproducing as it does in miniature the growth of the nation at large, the story of the Boston City Hospital has been one of rapid expansion and sensitive adjustment to the needs of those it serves. The hospital was dedicated on May 24, 1864, with special exercises attended by all members of the municipal government. Before its doors were thrown open to the public on June 1 final ceremonial inspection was made by Admiral Lesofsky and the officers of the Russian fleet, which was then lying in Boston Harbor.

From the very beginning, the new institution took upon itself responsibilities and obligations which might well have severely taxed a more mature enterprise. During its first full year of operation, 1865, it cared for 1066 patients, 18 of whom gave their occupation as "gentleman." After running five years it was caring for 3054 patients yearly. In 1934, after seventy years of service, more than 43,000 cases were cared for on its wards. More recent years report correspondingly large numbers.

During the first year of complete operation the daily average number of patients was 114. By 1897 this average had increased to 463. In 1932 it was 2155. In 1870, the first year for which accurate figures are available, patients stayed in the hospital on an average of 27 days. Fifteen years after its opening the average number of days' stay at the Main Hospital was 22. At the present time this has been lowered to 11.

Nevertheless, multiplicity of function alone, or mere numerical increase in the number of patients treated, is not a true index of an institution's real development. Progress on paper can often be achieved by a lowering of the standards of service or by a retreat from hard-won levels of efficiency. Thus, while there is no difficulty in showing, by means of a simple chart, the numerical growth of the Boston City Hospital, the true significance

*From the Neurological Unit of the Boston City Hospital and the Department of Diseases of the Nervous System, Harvard Medical School.
Assistant visiting neurologist, Boston City Hospital; associate in psychiatry, Harvard Medical School.

of the data lies in their demonstration of the increased effectiveness of the hospital, paralleling its growth in numbers

This development can be clearly indicated by fully considering the growth of the hospital as indicated by the increase in the daily average number of patients cared for and in the total number

Chart 1

of days' stay of all patients, taken in connection with the reduction in the average number of days' stay and in the mortality rate

First to be considered are the data which describe so vividly the numerical growth of the hospital. As has been stated, during 1865, the first full year of operation, 1066 patients were treated. During 1933 the hospital cared for 43,064 patients—equal to nearly one half the present population of Nevada and forty times as many patients as were treated in its first year.

Examples may be reported, taken at ten-year intervals, of the number of patients the hospital has cared for

YEAR	NO. OF PATIENTS
1870	3,054
1880	3,995
1890	6,510
1900	11,167
1910	12,970
1920	19,475
1930	32,968
1933	43,064

From these figures it is seen that during the first thirty years the growth in the number of patients admitted was gradual and proceeded at an even rate. From 1900 to 1920 this growth was accelerated. Since 1925 there has been a strikingly disproportionate increase, represented by nearly 2000 additional patients per year. The following table shows the average annual increase in admissions by fifteen-year periods

PERIOD	AVERAGE INCREASE
1865-1880	217
1880-1895	293
1895-1910	329
1910-1925	914
1925-1933	1962

On considering these figures, one is immediately struck with the difference between the growth of the Boston City Hospital and that of other public institutions—the Boston Psychopathic Hospital, for example. The latter has a settled policy of admitting about 2000 patients each year. As a result its rate of growth has remained practically stationary (and at full capacity) for two decades.

An examination of Chart 2 reveals the growth in the number of patients admitted to the Main Hospital alone and to the South Department—the department of contagious diseases—alone, as well as the total of their combined numbers. As is the case with the number of patients admitted to all departments, the growth in the Main Hospital during the first thirty years was gradual.

Chart 2

The next twenty years witnessed a more rapid inflow, while since 1920 the rate of growth in numbers has been unusually large. It is interesting to note that the South Department is today admitting fewer patients than at any time in its history. This fact may be taken as evidence of the great advances that have been made in the study of infectious diseases and the increased effectiveness of the Departments of Sanitation and Public Health in the city. As public education in the control of preventable diseases becomes more widespread, and as these departments achieve a more complete public co-operation, a continued drop in the admission rate to the South Department may be expected. The South Department, though still invaluable for isolation purposes, no longer fills the need, quaintly yet persistently presented by the superintendent and trustees in the first annual report.

We would call the attention of the City Council to the subject of the speedy erection of a building of moderate dimensions, to be used as a Foul Ward. There are at almost all times in such a hospital, cases of delirium, or patients affected with loathsome diseases, requiring separation for their own proper treatment, as well as for the safety and comfort of others.

To gain an idea of the relative number of patients handled in the different departments of the hospital, the following table is made up for the representative year 1931

	NUMBER OF PATIENTS	PERCENTAGE OF TOTAL PATIENTS
Main Hospital	30,921	86.0
Sanatorium Division	478	1.5
South Department	1,639	4.5
East Boston Relief Station	223	1.0
Haymarket Square Relief Station	2,237	6.0
Convalescent Home	305	1.0

The question naturally arises, What are the causes for this amazing hospital growth? Since the expansion of any public institution is only a function of the needs which it supplies and of the confidence which it inspires, the immediate answer to this question lies in the rapidly increasing public dependence upon tax-supported medical service, and a growing confidence in its competency which was formerly more quickly granted to private hos-

widespread. These are questions that need further study from every angle,—economic, sociologic and governmental,—and from the point of view of public relations. In connection with these questions, the following facts may be considered.

In the Out-Patient Department of the Boston City Hospital during the months of November and December, 1937, 5508 patients were interviewed by social workers before being admitted for treatment. Of these, 146 were steered elsewhere because they were not residents of Boston, 2312 were receiving definite aid in one form or another. On analyzing the incomes, it was found that 1166 patients had incomes under \$1000 a year, 951 had incomes of between \$1000 and \$1500, and 321 each received \$1500 or over. One thousand five hundred and five patients, or a little over 25 per cent, volunteered the information that they would be willing to pay an admission fee to the Out-Patient Department of from ten to twenty-five cents. Approximately 51 per cent of those applying for admission fell into the aided class (plus pensioners and city employees). Of the remaining 2882 patients, 2117 had incomes so low that taking into consideration the size of the family, the probable length of medical treatment, and other factors, they were unquestionably eligible for outpatient care. The percentage of patients on relief dropped 8 or 9 per cent from the previous year, but the salaries received by the unaided patients still were so close to the borderline that, with past debts (in some cases) to pay off, they were obviously eligible for care in the clinics.

Other factors have of course entered intimately into the growth of the Boston City Hospital. With advancing knowledge of medicine, the successful treatment of disease has come to depend more and more on skillful nursing and on a number of mechanical and chemical accessories not available in private homes. Since city treasuries are popularly supposed to be inexhaustible, the public easily assumes that a municipally supported hospital has the best equipment and the most complete resources. And when life or health is at stake most people are willing to endure the incidental discomforts of a public hospital if they can feel assured of good treatment.

Roughly speaking, the era of greatest initial development of the hospital coincides with other important social manifestations. One of these was the unrestricted immigration tide to America from Europe, that is said to have reached two peaks prior to 1900. As these newcomers became gradually adjusted to their new environment, they developed, in classes and groups, a wide appreciation of the treasures available to them in the various public institutions—schools, hospitals and clinics.

Chart 3

pitals and private practitioners. Originally this dependence was more restricted to the poorer classes, but recently the economic depression has forced it upon the middle class—the white-collar group—and having tasted the apple, they find it surprisingly good. In a day when state-supported medicine is a hotly debated question, the enormous recent growth of the Boston City Hospital is a portent worthy of note.

One may well wonder what social trends are responsible for this growth. Is it due to the disproportion between the mounting cost of medical care and the constantly low yearly income of the majority of families served by this hospital? Illness is apparently not increasing, and public education on the use of hospitals is obviously becoming more

With this enlarged view came an increased use of, and dependence on, these facilities. Just as it was not the native, indigenous stock which contributed most to the material development of metropolitan districts, neither was it the same stock which caused the noteworthy leap in hospital admissions.

The following facts, of special pertinence to the questions mentioned above, should be emphasized (Chart 1)

1 From 1860 to 1900 the population of Boston increased threefold. The growth in the number of patients admitted to the Boston City Hospital was roughly proportionate.

2 Since 1900, while the population of Boston has increased only 14 times, the number of patients admitted to the hospital has increased 4 times.

3 In the last ten years the patients admitted to the hospital have increased by more than 25 per cent over what constituted normal average admissions prior to this period.

These observations may be interpreted as indicating that hospital facilities, whatever be the cause of the growth, have at least adjusted themselves very sensitively to the needs and demands

Chart 4

of the city and at a rate far in advance of the rate of growth of the city's population.

The changes which have taken place in the average number of days' stay in the hospital are in part due to the process of specialization in the treatment of patients as it occurs in modern hospital practice. The contagious cases are handled by the South Department. The Convalescent Home* took care of patients not yet able to return to their work. The Sanatorium Division provides only for tuberculosis cases. This division of function leaves the Main Hospital free for surgical and medical cases where isolation is not required. As a result, the average length of stay

The Convalescent Home has not been open for the last few years.

in the Main Hospital has decreased from 27 days in 1871 to 11 days at the present time. At the Convalescent Home the length of stay decreased from 20 days in 1895 to 15 days in 1930. The length of stay in the Sanatorium Division, averaging as it does 6 months, naturally increases the hospital average when all departments are taken together. This department was opened in 1927 and in 1933 the length of stay averaged 198 days. In the South Department the length of stay has increased slightly from 30 days in 1900 to 32 days at the present time. Since 1905 the average stay at the Haymarket Square Relief Station has decreased from 2.3 days to 1.5 days. At the East Boston Relief Station there has been a decrease from 3.8 days in 1910 to 2 days.

As evidence of the increased effectiveness of the hospital, the lowered mortality rate is noteworthy. Death most frequently occurs in the hospital when

Chart 5

patients have been brought there in a dying condition—either as a result of severe accident or because of acute attacks of serious illness. Chart 4 shows the number of deaths in the hospital proper from 1864 to 1934. There was a gradual and even rise in number until 1892, and a considerable rise in 1894. There was a subsequent gradual rise until 1919, then a sharp increase occurred, due to epidemic influenza. From 1920 to 1922 there was a decrease in number, but since 1922 there has been a rapid increase. In the year 1932 the number of deaths totaled 2700. Nevertheless, despite this rise in the absolute number of deaths the mortality rate for the hospital proper has declined (Chart 5). Since 1864 the Boston City Hospital's death rate has varied from 67 to 131 per cent of total admissions. From 1894 to 1919 it averaged about 115 per cent. In 1920 it fell off to 79 per cent and has remained below 80 per cent since then.

For the last few years the rate has been below 7 per cent

Ranking today as the greatest hospital—in size and physical equipment—in one of the most im-

portant medical centers of this country, the Boston City Hospital is entitled to considerable praise for its honorable record of achievement in the past seventy-four years. It started very unpretentiously, and few would have imagined that in its development it would proportionately far outstrip the city it serves. The elasticity of its response and the sensitivity of its reaction to public need have now for many years been a revelation of the high seri-

ousness with which the officials and staff have chosen to regard their task

In the period of its first seventy years the hospital has treated 1,015,793 patients. Its original staff of a dozen men has grown until it now numbers nearly three hundred physicians on whom falls the daily burden of caring for the two thousand patients who are under its roof every day. As needs have arisen new services have been initiated, new

equipment has been installed, and safer and more efficient buildings have been erected. Happily too, the hospital's scientific spirit has developed step by step with its rise to physical eminence. Today it attracts physicians and students from every part of the world and, with a commendable lack of provincialism, counts graduates from every leading medical school in America as members and alumni of its staff.

All this has not been brought about by magic, though the sustained effectiveness with which it has happened at times has suggested magic. It has occurred by labor and through a system, by an ordered and natural way, starting first with human needs expressed in community life by conditions requiring special attention. The hospital was then founded, an organization and a plan were created and followed. The Boston City Hospital is, and has been from its beginning, a co-operative undertaking between citizen and taxpayer, councilor and mayor,

superintendent, trustees, medical, surgical, nursing and social-service staffs, hospital personnel and patients

In addition to the recognition naturally due the staff members many of whom have spent the bet-

ter part of their lives in free attendance, and the credit due the nursing personnel, whose wages do not in any way repay the services it gives, special appreciation is due the two groups of men who have most directly shaped and controlled the hospital's course they are the superintendents and the trustees of the past and present. These men have felt most keenly the responsibility they have shared, and in passing they deserve the most signal recognition for what they have done to make the hospital what it is.

Physicians and surgeons who have grown old in the service of suffering humanity insist that, in ministering to sick people, no slightest help that can be given them is without value or without benefit. Good nurses know that there can be healing in the

smoothing of a pillow and charity in the combing of a patient's hair. So it is when one thinks of seventy-four years and more than a million sick people one can catch some glimpse of all that this hospital has meant in terms of pain allayed, of suffering made endurable, and of men and women healed and made well again and restored to those who love them.

Suffering humanity is always appealing humanity. That is why the best title which the Boston City Hospital has won in all these years is that it has always been instant to answer the call of those who needed help, and unimaginably generous of itself and the service it is able to provide.

384 Commonwealth Avenue.

ASCORBIC ACID REQUIREMENTS IN EARLY INFANCY

THEODORE H. INGALLS, M.D.*

BOSTON

THE Health Committee of the League of Nations has recently set forth in its report¹ that "vitamin C should be given as from the age of three months," and that "the quantity given to children should correspond to a daily dose of not less than 5 mg. of ascorbic acid."

In the past we have had to rely on trial-and-error methods to ascertain the age level at which vitamin C should be added to the diet of artificially-fed infants, and likewise the time when the need arises in infants at the breast. Nor have we ever had a clear conception of the amount of antiscorbutic substance needed to prevent vitamin C deficiency. By the administration of pure ascorbic acid and the use of the indophenol titration method for assaying the concentration of ascorbic acid in urine, milk, tissues and plasma, these questions can now be answered with a certain degree of accuracy.

Good reasons exist for questioning the validity of both the statements just quoted that vitamin C should be given as from the age of three months, and that 5 mg. is an adequate daily dose. In the first place we know that clinical scurvy can develop before the age of three months. Thus, Jackson and Park² have reported the earliest case on record in an infant who died at twenty days, and Hagmann³ has cited a case of florid clinical scurvy in a child of three months who had had no orange juice the first two months of life, after which it was started in teaspoonful amounts.

That scurvy can occur before three months is also evidenced by an analysis of the necropsy protocols of 3 premature infants, whom we had the opportunity to observe. These patients were admitted within the first three days of life, and all suffered from acute infections of the upper respiratory tract. They died at the ages of fifty-seven, twenty-six and thirty-two days, respectively. During life these infants were maintained solely on

pooled, pasteurized human milk, a food which, as we shall demonstrate later, is grossly deficient in ascorbic acid. In each, definite evidences of scurvy were found histologically, although no clinical signs of the disease were observed (Figs. 1-4).

These findings are complemented by the data presented in Table 1 on 38 infants coming to autopsy before the fourth month of life. Twenty-five of these babies died either at birth or before

From the Department of Pediatrics, Harvard Medical School and the Infants and Children's Hospitals, Boston.

Read before the Regional Conference of the American Academy of Pediatrics at the Harvard Medical School, November 12, 1937.

*William Hunter Workman Fellow, Harvard Medical School, 1935-1937; resident in pediatrics, Massachusetts General Hospital.

the age of one month, in only 1 case was the reducing value of liver tissue less than 10 mg per 100 gm of tissue. Of 13 infants dying between the ages of one and four months, however, no less than 7 showed such a low value.

Although the data obtained by the assay of liver tissue, as well as that of urine and food, contribute much to our information regarding vitamin C deficiency, they must, as yet, be considered as somewhat qualitative rather than precisely quantitative. Further studies must be made before we can state positively to how great an extent the reducing substances in such specimens are actually representative of ascorbic acid. Nevertheless, the concentrations obtained in this relatively large number of infants tend to show that in the early months of life the storage in the tissues in existing circumstances may be comparatively low.

There are other data which also indicate that it is unwise to delay the addition of the vitamin C supplement until the age of three months.

Studies on adults,⁴ as well as on infants² between the ages of four and twenty-four months, have shown that the capacity of the tissues to store vitamin C is limited to so-called saturation. At this stage ascorbic acid supplied in excess of the daily requirement is largely excreted in the urine. Even a saturated individual when placed on a scorbutic dietary for three months exhausts his tissue depots by a combination of excretory and metabolic processes. These observations undoubtedly can be extended to newborn infants.

Although the development of clinical scurvy constitutes no serious threat in the ordinary course of events, and is an insidious process requiring considerable time to become manifest, it does not seem the part of wisdom to exhaust existing depots for one, two or three months before administering adequate daily doses.

We are, therefore, led to the conclusion that the daily ascorbic acid supplement should be added to the infant's dietary early in the neonatal period—for instance, in the first week of life. This seems especially important for premature infants, for the artificially fed and for those suffering from disease. Further studies are necessary before we can establish arbitrarily the requirements of the breast-fed infant. Such requirements obviously depend on variations of vitamin secretion in human milk.

Let us now consider the facts concerning the amount of ascorbic acid which would serve to protect the organism from developing vitamin C deficiency. It must be borne in mind that doses capable of preventing florid clinical scurvy may still be far below the optimum amount needed for perfect functioning of the organism. One approach to this problem lies in the quantitative

analysis of the ascorbic-acid content of cow's milk and mother's milk, since these substances comprise in the main the dietary of the newborn. In this regard it is necessary to ascertain the magnitude of vitamin content not alone in fresh milk, be it cow's milk or mother's milk, but especially in the substance just prior to consumption. As a result of numerous investigations,⁶⁻¹¹ the average vitamin C content of fresh mother's milk may be set at 0.4 mg per cubic centimeter, as shown in Table 2. The normal baby during the first three months of life in consuming from 500 to 1000 cc of breast milk per day will thus ingest the equivalent of 20 to 40 mg of vitamin C.

Table 2 *Average Vitamin C Content of Human Milk as Determined by Different Investigators*

	mg per cc
Wacholder ⁶	0.44
Kasahara et al	0.45
Stoer ⁷	0.50
de Haas et al ⁸	0.40
Selleg and King ¹⁰	0.55
Ingalls et al ¹¹	0.45
Average	0.43

Pasteurized cow's milk is a notoriously poor source of vitamin C. Over nine different days a random sampling of the milk supply of the Infants' Hospital revealed a vitamin C content too low to be determined, that is, less than 0.01 mg per cubic centimeter.

Except when the infant nurses at the breast, the situation is not a great deal better when mother's milk is utilized. Under marketing conditions, it has to be collected, pooled, pasteurized and disbursed, processes which facilitate the oxidation of ascorbic acid. Selleg and King¹⁰ noted the average loss in titration values for eleven samples of breast milk held in a refrigerator for eighteen hours to be 27 per cent.

Assay of pooled milk obtained from the Directory for Mother's Milk has revealed an average content of 0.26 mg per cubic centimeter.¹¹ After pasteurization and delivery to the ward, the value averaged 0.03 mg per cubic centimeter, or less than one tenth of the amount found in fresh mother's milk. Thus, it is improbable that any of the 3 infants included in this report received much more than 5 to 10 mg ascorbic acid per day from such milk. It is interesting to note that the vitamin C content of 500 to 1000 cc. of such milk approximates the fully prophylactic dose for a 300-gm guinea pig.

SUMMARY

1. Ascorbic acid nutrition is a relative term embracing several zones of vitamin depot between a protective saturation of the tissues and clinical scurvy. Scurvy can develop in infants as young as three months of age.

2 Judging from the known facts of ascorbic acid storage and utilization, it seems wisest to inaugurate the ascorbic acid supplement of artificially fed infants early in the neonatal period, rather than to defer it for several weeks.

3 Although data as to the exact daily dose desirable for small infants are meager, by inference from the amount present in breast milk and from clinical experience we may set the figure in the neighborhood of 20 to 30 mg of ascorbic acid a day, or its equivalent in 45 to 60 cc of orange juice.

CASE REPORTS

Case 1 K B., a premature female infant weighing 4 lb., 8 oz., was admitted to the hospital on the first day of life after a normal labor lasting 11 hours. The father

Figure 1 *Case 1* Low power photomicrograph of the costochondral junction showing abnormal persistence of dark-staining calcified cartilage columns, with interdigitating spicules forming a lattice. The remnant of previously formed bone shows up in lighter tone. There is cessation of osteoid deposition, atrophy of the hematopoietic substance and beginning overproliferation of stellate osteoblasts. Note the discontinuity of the cortex and several petechial extravasations of red blood cells just under the periosteum running diagonally across the upper left-hand corner of the photograph.

and mother and three siblings were dependent on welfare aid. The mother's health was good, her diet was without milk for the last 4 months of pregnancy and 'chiefly comprised hamburger and potatoes, with some vegetables, a little fruit and plenty of butter.

Examination revealed a small, well formed, premature infant with a husky cry and good color. The lungs showed slightly impaired resonance, and the breath sounds were heard poorly. There was a moderate systolic murmur. The spleen and liver were felt 1 cm. below the costal margins. The red-cell count was 5,110,000, and the hemoglobin 107 per cent. Spinal puncture revealed no cells in the spinal fluid.

The baby was starved for 12 hours and then started on 4 cc. of 5 per cent glucose, increased 4 cc. at a time every 4 hours until 25 cc. were given. Breast milk was slowly substituted, no cod liver oil or orange juice was given. The general condition remained good. In spite of an apparently good appetite and the absence of any

apparent infection, the infant did not gain weight. After a while she did not seem to see. The eyeballs became larger than normal, and a diffuse haziness of the cornea developed, after 4 or 5 weeks, evidence of pneumonia appeared, this slowly became more marked, vomiting occurred, and the child went steadily downhill and died on the 57th day of life.

From postmortem cultures of the heart's blood, right

and left lung and left ear *Staphylococcus aureus* and *Bacillus coli* were isolated. There were hemorrhagic and bronchopneumonic infiltrations of the lungs. Sections of the costochondral junction revealed changes consistent with scurvy, as shown in Figure 1. No evidences of vitamin A deficiency were manifest.

Case 2 W T., a premature male infant weighing 2 lb., 8 oz., was admitted to the hospital on the 1st day of life after a "hard delivery." The father was unemployed, the mother was in good health and worked as a waitress. During pregnancy her diet consisted of orange juice, grapefruit, occasionally cereal, eggs two to three times a week, toast and tea, soup and crackers, occasionally a

Figure 2 *Case 2* High power photomicrograph of the marrow substance near the costochondral junction showing atrophy of the hematopoietic substance and exposure of the loose textured reticulum.

meat, chicken or vegetable sandwich, and not much milk. The child was cyanotic and was resuscitated with difficulty. Examination revealed prematurity, molding of the skull and cyanosis. The case was otherwise not remarkable. The red-cell count was 4,300,000, and the hemoglobin 80 per cent. X rays of the long bones showed no abnormalities.

As the temperature was low, the baby was placed in an incubator. During the first 2 weeks of life he vomited bile stained material and lost weight. The stools were not remarkable, but the temperature was very unstable. The infant was transfused and given several cluses. He was fed by gavage, no cod liver oil or orange juice was given. On the 21st day a large stool was passed consist-

ing of mucus and blood. An exploratory laparotomy was done but no intussusception or obstruction was discovered. The baby went steadily downhill until death occurred on the 26th day of life.

mesentery for both large and small bowel. An acute peritonitis with fibrinous adhesions was found. The histologic findings in the ribs were consistent with those of scurvy, as shown in Figures 2 and 3.

Case 3 J. B., a premature male infant weighing 4 lb 8 oz., was admitted to the hospital on the 3rd day of life after an easy labor in the home. The father and mother and two siblings were dependent on city aid. The mother's diet and health during pregnancy were reported as good. Examination was not remarkable except for prematurity and icterus of the skin and sclerae. The heart and lungs were normal. The red and white-cell counts and the hemoglobin were normal. The urine was normal except for the presence of bile. X rays of the long bones showed nothing remarkable.

The patient did moderately well during the first 3 weeks of life, with a fair gain in weight, but despite incubator care he ran a consistently low temperature. No cod-liver oil or orange juice was given. During the 4th week he showed evidence of upper respiratory infection with rapid extension to the lungs. Vomiting and refusal followed. He was given a transfusion but showed a poor reaction to it. His condition became much more worse in

tive esophagus and hemosiderosis of the spleen. The histologic findings in the ribs were consistent with scurvy, as shown in Figure 4.

I acknowledge my indebtedness to Dr. Kenneth D. Blackfan for his advice and helpful interest in this problem.

2 Judging from the known facts of ascorbic acid storage and utilization, it seems wisest to inaugurate the ascorbic acid supplement of artificially fed infants early in the neonatal period, rather than to defer it for several weeks

3 Although data as to the exact daily dose desirable for small infants are meager, by inference from the amount present in breast milk and from clinical experience we may set the figure in the neighborhood of 20 to 30 mg of ascorbic acid a day, or its equivalent in 45 to 60 cc of orange juice

CASE REPORTS

Case 1 K B, a premature female infant weighing 4 lb, 8 oz., was admitted to the hospital on the first day of life after a normal labor lasting 11 hours. The father

Figure 1 *Case 1* Low power photomicrograph of the costochondral junction showing abnormal persistence of dark staining calcified cartilage columns, with interdigitating spicules forming a lattice. The remnant of previously formed bone shows up in lighter tone. There is cessation of osteoid deposition, atrophy of the hematopoietic substance, and beginning overproliferation of stellate osteoblasts. Note the discontinuity of the cortex and several petechial extravasations of red blood cells just under the periosteum running diagonally across the upper left-hand corner of the photograph

and mother and three siblings were dependent on welfare aid. The mother's health was good, her diet was with out milk for the last 4 months of pregnancy and chiefly comprised hamburger and potatoes, with some vegetables, a little fruit and plenty of butter.

Examination revealed a small, well formed, premature infant with a husky cry and good color. The lungs showed slightly impaired resonance, and the breath sounds were heard poorly. There was a moderate systolic murmur. The spleen and liver were felt 1 cm below the costal margins. The red-cell count was 5,110,000, and the hemoglobin 107 per cent. Spinal puncture revealed no cells in the spinal fluid.

The baby was starved for 12 hours and then started on 4 cc. of 5 per cent glucose, increased 4 cc. at a time every 4 hours until 25 cc. were given. Breast milk was slowly substituted, no cod liver oil or orange juice was given. The general condition remained good. In spite of an apparently good appetite and the absence of any

apparent infection, the infant did not gain weight. After a while she did not seem to see. The eyeballs became larger than normal, and a diffuse haziness of the cornea developed, after 4 or 5 weeks, evidence of pneumonia appeared, this slowly became more marked, vomiting occurred, and the child went steadily downhill and died on the 57th day of life.

From postmortem cultures of the heart's blood, right

and left lung and left ear *Staphylococcus aureus* and *Bacillus coli* were isolated. There were hemorrhagic and bronchopneumonic infiltrations of the lungs. Sections of the costochondral junction revealed changes consistent with scurvy, as shown in Figure 1. No evidences of vitamin A deficiency were manifest.

Case 2 W T, a premature male infant weighing 2 lb., 8 oz., was admitted to the hospital on the 1st day of life after a 'hard delivery'. The father was unemployed, the mother was in good health and worked as a waitress. During pregnancy her diet consisted of orange juice, grapefruit, occasionally cereal, eggs two to three times a week, toast and tea, soup and crackers, occasionally a

Figure 2 *Case 2* High power photomicrograph of the marrow substance near the costochondral junction, showing atrophy of the hematopoietic substance and exposure of the loose textured reticulum

meat, chicken or vegetable sandwich, and not much milk. The child was cyanotic and was resuscitated with difficulty. Examination revealed prematurity, molding of the skull and cyanosis. The case was otherwise not remarkable. The red-cell count was 4,300,000, and the hemoglobin 80 per cent. X rays of the long bones showed no abnormalities.

As the temperature was low, the baby was placed in an incubator. During the first 2 weeks of life he vomited bile stained material and lost weight. The stools were not remarkable, but the temperature was very unstable. The infant was transfused and given several clyses. He was fed by gavage, no cod liver oil or orange juice was given. On the 21st day a large stool was passed consist-

tate omission of the sulfanilamide. In these cases the fever subsided within a few days and failed to recur, even though the administration of the drug was continued.

Finally, there were 5 patients who presented fever as the chief manifestation of a toxic reaction but who, following discontinuation of the therapy and subsequent readministration of the drug, failed to show any further untoward response.

EFFECT OF SULFANILAMIDE ON THE COURSE OF RHEUMATIC FEVER

In the accompanying table we have summarized the incidence and manifestations of toxic reactions in the three different groups of cases composing this study. It is seen that of the 16 patients with moderate to severe rheumatic fever, all except 2 showed a definite febrile reaction—an incidence of 88 per cent. In the inactive group, fever occurred in only 1 case (6 per cent), and 76 per cent escaped without rash or fever. The group of patients with low-grade rheumatic fever manifested reactions which in frequency and character were intermediate between those shown by patients with severe and those with inactive rheumatic fever.

In spite of the rash and fever, patients in the inactive or low-grade rheumatic-fever groups manifesting a toxic sulfanilamide reaction seemed generally well and had no subjective symptoms. In striking contrast is the fact that toxic reactions made those with moderate to severe rheumatic fever feel and appear quite ill. Associated with the fever there was usually a rapid pulse, and pallor. Precordial or anterior chest pain was a frequent complaint.

In no case did sulfanilamide produce any symptomatic relief or shortening of the illness. In fact, in some cases the drug seemed to increase the severity of the disease. One patient with moderately active rheumatic fever had a febrile reaction on the fifth day of therapy, and although the drug was discontinued, this reaction was followed by an immediate rheumatic fever recrudescence characterized by persistent fever, new subcutaneous nodules and congestive failure. Another patient with active disease developed a rash and fever on the tenth day of treatment. In this case, three subsequent attempts at therapy produced further toxic reactions. Tolerance to the drug finally developed and the administration of sulfanilamide was continued for two months. During this period the patient not only failed to improve in appearance but also developed new subcutaneous nodules.

Four patients were treated during a rheumatic fever recrudescence. Fever was already present when the therapy was started. In all 4 cases, asso-

ciated with the giving of sulfanilamide there was a further rise in the temperature (up to 105°F), the pulse became very rapid, and there was an increase in pallor. All the patients became quite ill in appearance, and 2 developed severe joint pains. Following the omission of the drug, the temperature fell to a lower level and the appearance of the patients improved.

Two rather ill patients with severe cardiac involvement were given sulfanilamide at the time of an acute hemolytic streptococcal upper respiratory infection. In spite of the therapy there was an immediate rheumatic-fever recrudescence in each case. Subsequently, both patients died, one forty-two days and the other forty-eight days after the respiratory infection. During this period 2 other patients were treated for such infections with aspirin instead of sulfanilamide, and in both cases these episodes were followed by fatal rheumatic fever recrudescences. Two of these deaths have been previously reported.²

EFFECT OF SULFANILAMIDE ON CHOREA

There were 7 patients with slight to moderate chorea who were given sulfanilamide. Except for the chorea none of these presented any clinical signs or laboratory evidence of active rheumatic fever. Two had previously had active rheumatic fever, and 1 also had clinical evidence of heart disease. The period of drug therapy varied from two weeks to one month. Although 4 of the 7 patients developed a toxic rash, they subsequently became tolerant to the drug, so that treatment could be continued. The therapy had no effect on the natural course of the chorea in any of these patients.

DISCUSSION AND CONCLUSIONS

Toxic rash and fever associated with sulfanilamide therapy of streptococcal, meningococcal and gonococcal diseases have been reported by other investigators.²⁻⁷ Recurrence of the reaction with the subsequent administration of a single small dose of the drug, with positive skin tests in a few cases, has been offered as evidence that these toxic reactions are due to the development of a specific hypersensitivity.⁴⁻⁷ The demonstration here given that tolerance to relatively large amounts of sulfanilamide may develop following the repeated administration of small doses lends further support to the hypersensitivity hypothesis. However, the evidence is still far from proving conclusively that these reactions are due to a hypersensitivity similar to that seen in serum sickness and other allergic manifestations.

Nevertheless, the demonstration that a state of

THE EFFECT OF SULFANILAMIDE ON RHEUMATIC FEVER AND CHOREA

BOSTON

IN JANUARY, 1937, shortly after Long and Bliss¹ reported the value of sulfanilamide therapy for hemolytic streptococcal diseases, we began to investigate the effect of this drug on patients ill with rheumatic fever and chorea. Such a study seemed warranted because of the close relation of rheumatic fever to hemolytic streptococcal respiratory infections.

The primary purpose of this paper is to report our observations on the effect of sulfanilamide on rheumatic fever and chorea. In addition, we have included a description of certain interesting and important toxic reactions which were encountered.

MATERIAL STUDIED

A total of 58 patients have been treated with sulfanilamide‡. These may be divided into three groups: 16 who were moderately to severely ill with active rheumatic fever, 25 who were convalescing from rheumatic fever but still presented signs of borderline or low-grade active disease, and

Table 1 *Incidence of Rash and Fever Associated with Sulfanilamide Therapy in 58 Rheumatic Fever Subjects*

DEGREE OF RHEUMATIC FEVER	NO OF CASES	TOXIC REACTION	RASH ONLY	FEVER ONLY	RASH AND FEVER	NO RASH OR FEVER
Moderate to severe	16	14 (88%)	—	12 (75%)	2 (12%)	2 (12%)
Low grade (including 7 cases of chorea)	25	13 (52%)	3 (12%)	7 (28%)	3 (12%)	12 (48%)
Inactive	17	4 (24%)	3 (18%)	—	1 (6%)	13 (76%)
Totals	58	31 (53%)	6 (10%)	19 (33%)	6 (10%)	27 (47%)

17 in whom the infection had apparently become inactive. The second group includes 7 patients with active chorea but no other associated evidence of active rheumatic fever. The ages varied from four to twenty-three, and averaged eleven.

Sulfanilamide was administered in divided doses with a total daily dosage of approximately 6 to 7 gr per 10 lb of body weight during the first twenty-four hours, and thereafter 4 to 5 gr. A maintenance dose of more than 60 gr per day was rarely given. In some cases the drug was given in initial small doses, but thereafter the amount was gradual-

ly increased each day until the usual maintenance dose was reached. The duration of therapy varied from a few days to as long as two months.

TOXIC REACTIONS

Of the total of 58 patients given sulfanilamide, 31 (53 per cent) developed toxic reactions. The chief manifestations were rash and fever. The rash was pink or red and usually maculopapular, and occurred on all parts of the body. It was most intense and commonest on the elbows and extensor surfaces of the forearms, and to a lesser extent over the knees and extensor surfaces of the legs. It was observed only once on the face and the palms. It was rarely urticarial, and in 1 case was partially purpuric. Associated with the rash there was slight, if any, itching.

The other important manifestation of this toxic reaction was fever. In some cases the rash was associated with no fever or only slight fever. Occasionally the rectal temperature rose as high as 103°F. On the other hand, fever frequently occurred without any associated rash, and in these cases was usually higher than that which accompanied a rash. These toxic reactions occurred most frequently between the seventh and the twelfth day after the beginning of the drug therapy, but were observed as early as the second and as late as the thirtieth day.

When a toxic rash or fever developed, therapy was usually discontinued and the manifestations of the reaction disappeared within one to three days. Of the 31 patients who developed reactions, 12 had a rash either alone or associated with fever. Of these, 10 were again given sulfanilamide. In some cases the second administration consisted of a single dose of one 5 gr tablet. In 9 of these 10 cases there was a recurrence of a toxic reaction within twenty-four hours, and the drug was again discontinued. Repeated administrations of small doses of sulfanilamide caused repeated reactions, which lessened in severity and finally failed to reappear, even though the dosage was gradually increased to the original amount and was continued for as long as three weeks. The number of reactions observed in a given case before the development of tolerance varied in different individuals from two to six.

There were 2 patients who developed febrile reactions which were not severe enough to necessi-

mous epithelium generally begins next to the high columnar epithelium, the greater part of the initial carcinoma in such cases may develop by carcinomatous transformation of the squamous epithelium which lines the cervical canal. A superficial initial carcinoma without any downgrowth is thus formed, and only a comparatively small part of the carcinoma may be visible at the external os during a speculum examination. If the possibility of squamous epithelium in the cervical canal is overlooked, and a low amputation of the cervix performed, parts of the carcinoma may be left behind. To circumvent such failures, radium as a postoperative routine is indicated rather than a more radical operation.

The most frequent lesion of the cervix is erosion. By this term is meant a defect only in the epithelium as compared with an ulcer, in which the underlying connective tissue is also defective. Whereas erosion of the cervical squamous epithelium is found not too rarely, erosions of the vagina are comparatively infrequent. There are two major reasons for this. One is that the fixation of the vaginal epithelium to the underlying stroma is guaranteed by numerous dovetailing papillae, while in the cervix these papillae are rarer, thinner and smaller, and in some cases, completely absent, secondly, the mechanical tension on the height of the convex cervix is much greater than that on the concave surface of the vagina. The precipitating cause of most of the erosions is the macerating influence of a discharge, whose fluid primarily and directly acts on the cervical epithelium. This accounts for the fact that in nearly all cases of erosion a final and permanent healing can only be achieved when the causal discharge stops, and suggests that routine therapy of erosion should begin with the treatment of the discharge, that is, of the cervicitis. In the healing of an erosion at the junction of the histologic os an activity of both types of epithelium is observed: the columnar from the cervical canal and the squamous from the periphery, both trying to establish themselves on the free and naked surface of the erosion. The columnar epithelium, which consists of one row of cells only, grows more quickly and succeeds in covering most of the field of the erosion. This we call the first stage of healing. Later on, the slower-growing squamous epithelium begins to creep over or under the columnar layer. This is the second stage of healing. This process holds true for the simple erosion. However, in numerous cases the field of the erosion contains glands which are the remnants of a congenital eversion or have developed during the first stage of healing. In such cases, the second stage does not represent a complete healing, as the pressure from the secretions of the glands tends to force

off the surface squamous epithelium. This produces a recurrence of the erosions. A final healing of these glandular erosions takes place only when the squamous epithelium plugs the glands permanently by sending downgrowths into them. Such a procedure, which is a physiologic process of healing based on the normal activity of squamous epithelium, takes a comparatively long time. As a general rule neither the columnar nor the squamous epithelium can grow over the ground of the erosion so long as the tissue is heavily inflamed. The therapy of the erosion therefore falls into three stages: first, the healing of the discharge, secondly, the combating of the inflammation, and thirdly, the stimulating of the potential activity of the neighboring squamous epithelium by substances that support epithelial growth, such as scarlet red.

The most important lesion of the cervix is squamous-cell carcinoma, which accounts for about 90 per cent of the uterine carcinomas, whereas the type arising from the glandular epithelium of the cervix represents roughly 2 per cent. The balance, 8 per cent, is accounted for by carcinoma of the endometrium. This squamous-cell carcinoma begins by carcinomatous transformation of the surface epithelium which takes place, not in the depth, but on the surface, and not in the field of an erosion, but in the intact epithelium. The carcinomatous surface epithelium, the so-called carcinomatous *Belag*, is generally of the same dimensions as the normal epithelium and differs only by the carcinomatous character of the polymorphous and atypical cells, with their hyperchromatic nuclei. There is always a clear-cut cleavage line between normal and carcinomatous epithelium and never a gradual transitional zone. This, the first phase of carcinomatous epithelium, can last many months or perhaps a few years. Later on, in the second phase, the carcinomatous epithelium shows downgrowths, and finally, in the third phase, ulceration takes place. Prior to the third phase, the surface is smooth and naked-eye examination reveals apparently normal tissue. There are a few cases where a clinical diagnosis of carcinoma can be made. Three characteristics make this possible: first, the slightly elevated level of the carcinomatous epithelium, secondly, its finely wrinkled surface, and thirdly, its pale color. However, in a large majority of cases these characteristics are either completely absent or poorly developed.

In these cases, a biological difference between normal and carcinomatous epithelium can be utilized to establish a clinically visible difference in the two epitheliums. The normal epithelium of the cervix contains, in the superficial cell layers, large quantities of granular glycogen, which is produced and stored by the cells. Carcinomatous epithelium

tolerance can be brought about may be of some practical importance in cases where a toxic rash or fever appears in an individual being treated with sulfanilamide for a disease which usually responds to the drug

Hageman and Blake⁴ observed febrile reactions in 21 of 134 cases being treated with sulfanilamide, an incidence of 16 per cent, while Schwentker and Gelman³ noted a rash in 10 out of 180 patients (6 per cent). In contrast to these figures is the high incidence of toxic rash and fever in our series (53 per cent). Furthermore, an analysis of our patients shows that those with active rheumatic fever are more prone to develop febrile reactions than are those in whom the disease is quiescent. We can offer no explanation of this difference.

Recurrences of rheumatic fever following hemolytic streptococcal respiratory infections in spite of sulfanilamide therapy, and the lack of beneficial effects of this drug on the course of rheumatic fever and chorea, have been noted above. Because of these facts, and because rheumatic fever patients are very prone to develop severe febrile reactions to sulfanilamide, we believe that the administration of this drug is contraindicated in the presence of active rheumatic fever.

SUMMARY

1 Sulfanilamide was administered to 58 rheumatic-fever patients.

2 After two days or more of drug therapy a toxic rash or fever developed in 53 per cent of the cases.

3 In 9 individuals manifesting such toxic reactions, the repeated administration of small doses caused the development of a state of tolerance.

4 Patients ill with active rheumatic fever were particularly prone to develop severe febrile reactions. This fact, together with the lack of any observed beneficial results, makes the administration of sulfanilamide contraindicated in the presence of active rheumatic fever.

VERMONT STATE MEDICAL SOCIETY

EARLY DIAGNOSIS OF CANCER OF THE CERVIX UTERI

WALTER SCHILLER, M.D.*

CHICAGO

THE human cervix uteri consists of two entities—the external os and the internal os. By naked-eye inspection the external os is defined as that point between the narrow cervical canal and the surface of the vaginal portion (portio vaginalis) of the uterus. This we call the anatomic external os as it is determined by anatomical means. By microscopical examination, the external os is defined as that point where the non-hornified stratified squamous epithelium of the portio meets the high columnar mucinous epithelium, containing many glands, which lines the cervical canal. This we call the histologic external os as it is determined with the aid of the microscope. Normally the anatomic external os and the histologic external os coincide, but epithelium typical of the external os may extend inside or outside the normal anatomical limits. Such conditions are to be judged as pathologic and are not too rare.

When the cervical mucous membrane is not limited to the cervical canal but extends out to cover, in varying degrees, the area about the external os, we have an abnormality which occurs in a certain disturbance of fetal development. This congenital eversion was found to be present in more than 20 per cent of all newborn girls by the late embryologist, Fischel, who published these findings in one of his early papers. In the first few months of extrauterine life, the misplaced cervical epithelium becomes replaced by squamous epithelium, and the abnormality is thus corrected. Only a small percentage of all women retain this congenital eversion throughout life.

On the other hand, in hypoplastic individuals with genital infantilism we find that the squamous epithelium of the external os ascends into the lower part of the cervical canal, occasionally up to half or even three quarters of its length. This variation is of great practical importance in certain cases of carcinoma. Since carcinoma of the squa-

of prostatic age, the frequency of urinary symptoms in the female and the effects of infection of the urinary tract are factors which must be evaluated before a definite diagnosis of true neurogenic vesical dysfunction in pernicious anemia can be established, but the number of cases recognized would be materially augmented if in taking the history a detailed questioning of the patient were insisted on in order to detect those symptoms which might be the signal of vesical involvement, and if some definite plan of urological investigation were carried out. By this program many cases of asymptomatic or preclinical vesical dysfunction would be diagnosed.

Before discussing the urinary tract disturbances it is essential that we be cognizant of the underlying pathology of the disease. It is well recognized and generally accepted that neurologic manifestations in pernicious anemia are dependent on pathologic changes in the posterior and lateral columns of the spinal cord. It is obvious that, as a result of such changes, interference with the normal physiology of the bladder will occur in many individuals, and that they will present the signs and symptoms of neurogenic vesical dysfunction.

Symptoms of vesical dysfunction in pernicious anemia depend in great measure upon the stage of the disease in which the patient is first seen and upon the presence or absence of infection of the urinary tract. It should be emphasized that definite bladder involvement may be present with symptoms referable to the urinary tract so mild that no significance may be attached to them either by the patient or by the examining physician or the patient may be seen in the asymptomatic stage, at which time a diagnosis of vesical dysfunction can be made only by cystometric study. In most cases the earliest symptom of such dysfunction is bladder difficulty. This may present itself as initial retardation or hesitancy, diminished force of the urinary stream, terminal dribbling or the sensation of incompletely emptying the bladder. Such symptoms are, of course, also consistent with obstructive changes at the bladder neck. As impairment of vesical sensation progresses, the individual becomes less conscious of bladder fullness, and the interval between voidings is prolonged. Vesical distention and urinary retention increase, and finally overflow incontinence develops. Frequency, urgency and painful urination are encountered with the advent of infection, which is frequently the result of injudicious catheterization. Renal pain, chills, fever and toxemia indicative of upper urinary tract involvement develop in many cases and an advanced pyelonephritis commonly results. It should be noted that marked renal damage can occur in these patients in the

absence of local signs or symptoms referable to the kidneys. In a series of postmortem examinations on pernicious-anemia patients, Goldhamer et al.⁵ found renal damage in 83 per cent of the group.

The recognition of neurogenic vesical dysfunction in patients suffering from pernicious anemia is at times extremely difficult, especially in the early and borderline groups. Prompt diagnosis is essential, however, and the timely institution of effective treatment is imperative so that the progress of vesical dysfunction can be arrested and further damage to the bladder prevented. Where we are dealing with an atypical or relatively normal blood picture, the diagnosis of primary anemia may be established by urological study. A definite program of study should be carried out directed to the differentiation of the obstructed and the neurogenically disturbed bladder. It must be understood that they may coexist in many cases. It is well known that bladder paralysis due to spinal-cord disease is most frequently produced by tabes dorsalis, and this factor must be definitely excluded. Cystoscopy and cystometry are invaluable. Inspection of the bladder outlet is particularly helpful in proving the absence of definite obstruction as the chief factor in the urinary story.

The appearance of the bladder itself in pernicious anemia is not characteristic. As might be expected, it resembles in every particular the "tabetic" bladder and presents the picture of diffuse fine trabeculation, diminished sensibility to instrumentation, increased tolerance to distention and a sluggish expulsive force. The rectal sphincter is in many instances relaxed. Cystometric examination is the most informing diagnostic procedure, as the response of the bladder musculature to a process of gradual stretching and the patient's sensory reaction to its filling are the most delicate criteria of neurogenic disturbance, and the finest index of neurogenic improvement following the institution of liver therapy. In the pernicious-anemia bladder, the normal gradual ascendancy of the pressure curve becomes flattened in various degrees, the first indication to void is prolonged, and the maximum voluntary pressure is diminished.

Marked urinary disturbances may predominate in some cases, with the result that the patient first consults the urologist because of symptoms referable to the genitourinary tract, and the latter must be careful not to overlook the underlying primary disease. On the other hand, all cases of pernicious anemia, with or without apparent neurologic involvement and whether or not presenting an atypical blood picture, should be studied with the possibility of a preclinical or early neurogenic bladder in mind. Attention must be directed particularly

loses the potency to produce as well as to store glycogen and is therefore free from this substance. To differentiate the glycogen-containing and glycogen-free areas, the cervix is brought in contact with a dilute aqueous solution of iodine. The best solution has been found to be one containing 1 gm. of iodine, 2 gm. of potassium iodide and 300 cc. of water. This solution stains the normal, glycogen-containing cervical epithelium a dark brown, whereas carcinomatous epithelium remains pale. In carrying out this procedure the following steps are employed: first, expose and clean the cervix, secondly, pour 10 or 20 cc. of the iodine solution into the vagina, being careful to distribute it throughout, and thirdly, after 40 to 60 seconds examine the cervix carefully. Brown areas are normal, pale, unstained areas are suggestive of carcinoma but are not pathognomonic. There are several other pathologic changes which also prevent the production and storage of glycogen. Hyperkeratosis from prolapse, in consequence of syphilis or of the idiopathic type, can be responsible for unstained areas. Which one of these various causes is responsible for the absence of staining must be determined histologically. Since only a biopsy of the surface epithelium is necessary, there is no need for an exploratory excision. Scraping the surface epithelium with a sharp curet is sufficient. *The diagnosis can and should be made before the phase of downgrowth.*

Years of experience have proved that carcinoma usually begins in perfectly normal cervixes. The

test should not be confined to suspicious cases, such as elderly women with eroded cervixes, but should be done as a routine procedure in all patients with gynecological complaints and, if possible, in all women, including the comparatively young. If the latter were possible, we should be able to discover carcinoma of the cervix in a phase of its development which would offer a chance of cure of nearly 100 per cent.

DISCUSSION

DR. PATRICK E. MCSWEENEY, Burlington. I express my thanks and appreciation to Dr. Schiller for his excellent paper. There are a few points which I should like to emphasize. The instruction of the laity in the necessity of periodic health examinations has brought many women to us in the so-called precancerous stage. By carrying out the following procedures the death rate from cancer, in my opinion, can be reduced 50 per cent.

First, every woman past the age of thirty-five should be examined vaginally every six to eight months. Visualization of the vagina and cervix by speculum is a necessary part of the examination.

Secondly, women past the age of thirty-five who have borne children should undergo some method of surgical repair of the cervix, if indicated.

Thirdly, vaginal discharge should be traced to its origin and cleared up if possible. Vaginal discharge is a frequent cause of erosions, which in turn may be precancerous lesions.

Fourthly, early cancer of the cervix can best be treated by radium (2000 to 3000 mg. hours).

Fifthly, advanced cases of cancer of the cervix are best treated by radium (4000 to 6000 mg. hours).

DISTURBANCES OF BLADDER FUNCTION IN PERNICIOUS ANEMIA

CHARLES J. E. KICKHAM, M.D.,* AND WILLIAM C. MOLONEY, M.D.†

BOSTON

TOO little attention has been directed to the fact that disturbances of bladder function are among the frequent manifestations of neurologic involvement in pernicious anemia. Woltmann¹ in 1919 published the first statistical study of the subject, and reported from his series an incidence of bladder involvement of 13.6 per cent, reference to vesical complications had been made in earlier contributions by Bowman,² Taylor³ and Billings.⁴ Goldhamer and his collaborators,⁵ in 1934, emphasized the high incidence of vesical dysfunction in pernicious anemia, while Hyland and Farquharson,⁶ in a recent excellent contribution, have reported a 21 per cent incidence in a study of 172 cases.

On the other hand, Caulk⁷ did not record a single case of pernicious anemia with bladder disturbance in a series of 500 cases of so-called cord bladder, for which Smith and Engel⁸ have suggested the more appropriate term "neurogenic vesical dysfunction." Kretschmer⁹ in 1921 discussed this aspect of the disease in the urological literature. There have been no other urological papers on the subject.

With improved neurological diagnosis, the advent of liver therapy and the recent advances in the art of cystometry, further investigation of this most important phase of pernicious anemia might well have been anticipated. It is the purpose of this paper to emphasize the importance of recognizing vesical dysfunction in this disease, and to describe briefly its general features. To be sure the common occurrence of bladder disturbances in men

†Assistant physician and director of Blood Clinic, Carney Hospital.

phocytes 47 per cent, eosinophils 4 per cent and monocytes 5 per cent. The blood urea nitrogen was 33 mg per cent. The blood Hinton and spinal fluid Wassermann tests were negative. The urine was cloudy and alkaline with a specific gravity of 1.016, there was a trace of albumin but no sugar. The sediment contained a large amount of pus. Culture showed *Bacillus coli* and *Staphylococcus aureus*. A phenolsulfonphthalein 2-hour renal function test showed 10 per cent excretion the first hour and 14 per cent the second. Gastric analysis revealed no free hydrochloric acid. The hematocrit determination demonstrated an MCV of 122 μ^3 . Cystoscopy revealed a classical picture of cord bladder, with evidences of marked infection. Cystometry showed a markedly atonic bladder with the first desire to void occurring after 520 cc. had been injected, with a resulting intravesical pressure of 12 mm. of mercury. The maximum voluntary pressure was 35 mm. at 760 cc.

Following admission, the patient was placed on indwelling catheter drainage, the bladder was emptied by gradual decompression, and a closed system of irrigation was effected. He was given concentrated liver extract intramuscularly, and because of the low hemoglobin, ferrous sulfate was administered. Ammonium chloride and mandelic acid were given to combat urosepsis. On this program there was gradual clinical and laboratory improvement. The red cells reached 5,420,000, and the hematocrit reading fell to 88 μ^3 . There was marked neurologic improvement. The gait was much better. The Romberg test became negative and the Babinski reflex disappeared. There was no improvement of the vibratory sensation. In other words, there was regression of some neurologic signs with progression of none. On July 28, 1937, the cystometric study disclosed marked improvement, although the bladder was still far from normal. The first desire to void was at 350 cc. with a pressure of 20 mm., and the maximum voluntary pressure was 64 mm. at 600 cc. The urethral catheter was removed 1 month later, after which the patient voided without difficulty in satisfactory amounts. The residual was as low as 120 cc. In spite of continuous liver therapy, however, urinary symptoms recurred, the residual urine mounted, and the patient finally developed a septic temperature with toxemia. A suprapubic cystostomy was done on October 7. The convalescence was uneventful. The patient was discharged on suprapubic drainage on November 29.

This patient on admission presented a problem in diagnosis. However, in view of the physical and neurological findings, the laboratory data, the negative serological tests and the cystometric readings,

we decided that the case was one of advanced neurogenic vesical dysfunction due to pernicious anemia. The marked return to normal of the blood picture, the clinical progress and the cystometric improvement confirmed this diagnosis. In this case, however, cord damage of an irreversible nature had doubtlessly taken place, with the result that irrecoverable damage to the detrusor had developed. The important role of urosepsis as an additional deleterious factor is well demonstrated, since it precipitated the necessity for surgical drainage.

SUMMARY

The importance of early recognition of neurogenic vesical dysfunction in pernicious anemia and the necessity of prompt and adequate liver therapy in order to prevent irrecoverable cord and detrusor damage are emphasized.

Cystometry is shown to be an accurate diagnostic procedure in both preclinical and clinical vesical dysfunction of neurogenic origin and to be the most important qualitative index of recovery.

Two illustrative cases are recorded.

to this type of case as it is here that early diagnosis may be missed

There has been some diversity of opinion as to the efficacy of liver therapy on the neurologic lesions of pernicious anemia. However, recent studies, notably those by Hyland and Farquharson⁹ and by Strauss and his co-workers,¹⁰ have shown that adequate liver therapy can prevent the development of central-nervous-system involvement, and that if such changes have taken place, it can arrest and cause regression of the process. Certainly, intensive, prolonged and adequate parenteral liver therapy should be the watchword in cases with vesical disturbances. Unless the institution of treatment is prompt and adequate, especially when the lesions are well established, the detrusor may become so atonic that its contractility is permanently lost, even though the cord injury may be reparable. A specific program of urological therapy is not indicated in the earlier stages, although general measures should be employed, directed to the prevention of urosepsis and of deteriorative changes in the upper urinary tract. As vesical dysfunction progresses and bladder symptoms develop, accompanied by urinary retention, attempts to improve the expulsive power of the detrusor by medication and education should be made. More drastic measures are essential when we are dealing with an infected bladder and when the clinical picture suggests a pyelonephritis or an impending uremia. In this group, continuous vesical drainage must be accomplished either through the indwelling catheter—a hazardous procedure—or by suprapubic cystostomy. Tidal drainage as described by Munro and Hahn¹¹ is of great value in these patients.

Case 1 An American male, aged 61, entered the Blood Clinic of the Carney Hospital on July 30, 1937, complaining of numbness of the extremities and a staggering gait of 2 years' duration. There was a history of gradual loss of weight and strength, a sore tongue, some gastric distress and recent dyspnea and palpitation. The patient also experienced difficulty in initiating the flow of the urinary stream, had a sensation of incomplete emptying of the bladder, and had terminal dribbling. The symptoms had been progressive. The most annoying feature of the illness was the staggering gait.

Physical examination showed a fairly well-developed and well-nourished man with a very sallow complexion. The hair was gray. The tongue was pale, smooth and glossy. There was marked edema of both lower extremities. The rectal sphincter was slightly relaxed. The prostate was small, soft and benign. The vibratory sense was absent in the upper and lower extremities. The gait was ataxic. The position sense test of finger to nose was satisfactory, that of heel to heel was poor. The Romberg test was positive. Reflexes of the biceps, triceps and extensors were equal and active, the knee and ankle jerks were absent. The Babinski was doubtful. The sensorium was clear. There was definite weakness of the upper and lower extremities. The red blood-cell count was 1,530,000, the white-blood-cell count 1600, and the hemoglobin 48 per cent. On smear there was definite macrocytosis, no nucleated red cells

were seen, the polymorphonuclears numbered 49 per cent, lymphocytes 47 per cent, eosinophils 3 per cent and monocytes 1 per cent. A blood Wassermann test was negative. The urine was clear, amber and acid, with a specific gravity of 1.018. There was no albumin and no sugar. The sediment contained occasional white blood cells and epithelial cells. The culture was negative. The residual urine measured 15 cc. Cystometry showed a somewhat atonic bladder with the initial desire to void after 350 cc. had been injected with a resulting intravesical pressure of 14 mm. of mercury. The maximum voluntary pressure was 32 mm. at 480 cc. Gastric analysis showed no free hydrochloric acid.

On admission a diagnosis of pernicious anemia with combined degenerative disease of the spinal cord was made. Cystometric study suggested early neurogenic vesical dysfunction. The patient was placed on a program of adequate parenteral liver therapy. There was steady improvement. Eleven weeks after the institution of therapy, the red-cell count was 5,880,000, and the hemoglobin 98 per cent. Neurologic improvement was dramatic, and the bladder difficulties markedly improved. The last cystometric readings were the initial desire to void was at 220 cc., with 16 mm. pressure, the maximum voluntary pressure was 54 mm. at 475 cc., there was no change in the residual urine.

This case is an illustration of early neurogenic vesical dysfunction in pernicious anemia. The clinical and cystometric improvement shows conclusively the efficacy of liver therapy in neurologic manifestations of the disease.

Case 2 An American male, aged 70, was admitted to the Carney Hospital on May 17, 1937, complaining of inability to void. There was a history of progressive loss of strength for 4 years. He was uncertain as to the date of onset of his bladder difficulty, but had had nocturia, hesitancy and a sensation of incompletely emptying his bladder for 1 year. His gait was stumbling in character. He experienced considerable gastric distress. The patient had always been well prior to his present illness, although at the age of 24 he had had some injection treatments for what he thought might have been syphilis. The past history and family history were otherwise irrelevant.

Physical examination revealed a pale, elderly man in no apparent distress. The hair was thin and gray. The tongue was glossy. The pupils were equal and reacted to light and distance. The heart and lungs were negative. There was a large, non-tender mass in the lower mid-abdomen, which was flat by percussion. The kidney regions were negative. The external genitals were negative. Digital examination of the rectum found the sphincter relaxed. The prostate was small, soft and benign. There was slight pitting edema of both lower extremities. The sensorium was clear. There was no cranial nerve involvement. Sensory disturbances consisted of slightly diminished perception of heat and cold, and of slight touch and pinprick in the lower extremities. The vibratory sense was absent in the lower extremities. There was no motor involvement except weakness in the legs. The deep reflexes in the upper extremities were equal and active. The Hoffmann sign was not present. The knee jerks were hyperactive equally. The ankle jerks were normal. The Babinski was present. The Romberg was positive. The gait was not typical. The red blood cell count was 2,920,000, the white-blood-cell count 10,450, and the hemoglobin 50 per cent. On smear the red cells were normal in size and achromic, the platelets were normal, the polymorphonuclears numbered 44 per cent, lym-

deepest pair of forceps. With a Kelly hemostat each pair of forceps was grasped and removed through the perineal incision. A No. 20 Fr urethral catheter was placed for continuous bladder drainage, and the perineal wound was closed, with drainage. The convalescence was prolonged because the patient was unco-operative and removed his catheter several times and also because there was a more or less septic condition of the urethra, due to the length of time the forceps had remained there.

SUMMARY

A case of foreign bodies (three pairs of tissue forceps) in the urethra of a man with multiple sclerosis is described. Following operative removal, the patient made a complete, though delayed, recovery from his urethral difficulties.

FOREIGN BODIES IN MALE URETHRA

Report of an Unusual Case

AUGUSTUS RILEY, MD *

BOSTON

THE case of a man with multiple sclerosis who was recently treated at the Boston City Hospital for foreign bodies in his urethra is so unique that it should be reported

CASE REPORT

A 34 year-old man was admitted to the hospital complaining of 'three pairs of tweezers' in his urethra. He

Figure 1. This photograph shows the prongs of one pair of tissue forceps protruding through the glans penis on either side of midline just below the external meatus, and the sinus at the penoscrotal angle

stated that 2 years previously, when he and "a girl friend were just playing around, the first pair of forceps was pushed into the urethra, with the closed end foremost. A second forceps, he said, was inserted some time later in an attempt to extract the first, and about 6 months before his coming to the hospital a third forceps was inserted in an effort to remove the other two. He offered no explanation as to why each forceps had been inserted with the closed end first, even when asked how he had expected to grasp the other forceps in that manner. There had been only slight pain and no urinary difficulty previous to admission.

About 6 years before, the patient noticed that his right leg gave way when he was walking. Five years previously he awoke one morning with numbness of both legs, and was unable to move them. A short time later he began to have weakness in the left leg to as great a degree as in the right. It increased so much that he had to give up

his job as a truck driver. On entry he was unsteady when standing alone, and was unable to walk unassisted.

Physical examination showed a somewhat emaciated, white male, with marked scoliosis and kyphosis, who was unable to walk without assistance. The glans penis was penetrated on both sides of the frenum just below the external meatus by the prongs of a pair of tissue forceps, which extended about 1 cm. beyond the under surface of the glans. The forceps was about 10 cm. long, and was easily palpable in the urethra with the closed end at the penoscrotal angle. At that angle there was a urethral fistula and the prongs of another forceps could be felt. About 1 cm. deeper in the urethra the prongs of a third forceps were felt. The closed ends of the second and third

Figure 2. The three pairs of forceps removed from the urethra. The pair showing the most erosion was farthest in the urethra and apparently was the first to be introduced

pairs were felt in the perineal portion of the urethra.

The patient was well oriented and co-operative, and expressed no abnormal ideas, but seemed distinctly irrational. Examination of the cranial nerves was negative. There was a marked weakness of both legs and to a lesser extent of the right hand. The gait was unsteady. There was no definite level of sensory disturbance. The vibratory sense in the ankles was lost. There was hyperesthesia of the legs and trunk to pinprick. There were a positive Babinski and exaggerated ankle clonus and ankle jerks. The reflexes of the right arm were more active than those of the left. The right foot and ankle were cyanotic, and colder than the left. On laboratory examination the spinal fluid and blood were normal.

A diagnosis was made of multiple foreign bodies in the urethra and multiple sclerosis.

Operation was performed under spinal anesthesia. A perineal urethrotomy was made over the closed end of the

TRACY B. MALLORY, M.D., *Editor*

CASE 24211

PRESENTATION OF CASE

A sixty-seven-year-old, white, American man entered the hospital with the complaint of epigastric pain of eleven days' duration.

Seven years before entry he was hospitalized for one week for "intestinal stoppage." Treatment consisted of turpentine stupes and enemas, and he was discharged well. He was well until six months before entry when he began to have epigastric distress and gas pains which were greatly relieved by food and soda. For the next four months he continued to have these symptoms, but they became less severe. About two months before entry he began to have indigestion which to him meant a dull nonradiating ache in the upper abdomen with gaseous eructations and loss of appetite. He also had increasing constipation. Eleven days before entry he was awakened from sleep at two o'clock in the morning by a persistent, sharp, moderately severe, nonradiating, epigastric pain accompanied by some nausea but no vomiting. He did not sleep any more that night, but the following morning was able to do his work driving a bus. The pain continued and two or three days later became more severe, forcing him to go to a hospital where he remained up to the time of entry here. The pain was not relieved by taking food. During the acute illness he had almost no appetite, and in spite of enemas, passed only a little gas by rectum and very little feces. He did not know whether he had lost weight. He had no jaundice, chills, colicky pain, hematemesis, melena or genitourinary symptoms. For some time he had been treated by his physician for angina pectoris and regularly took "white pills" under his tongue for relief of his attacks. He stated that the pain of his present illness in no way resembled his anginal pain. His past history was otherwise negative, and his family history was noncontributory.

Physical examination revealed a well-developed, fairly well-nourished man complaining of moderate abdominal distress. The heart was slightly enlarged to the left, but the chest was otherwise negative. The blood pressure was 130 systolic, 70 diastolic. The abdomen was moderately distended and tympanitic throughout except in the right lower quadrant where it was dull. There was gener-

alized tenderness, most marked in the epigastrium. No masses were made out, and liver dullness was obliterated. Peristalsis was diminished but high-pitched in tone. Rectal examination was negative.

The temperature was 99.5°F., the pulse 75. The respirations were 20.

The blood showed a red-cell count of 4,800,000 with 75 per cent hemoglobin, and a white-cell count of 13,200 with 88 per cent polymorphonuclears. The nonprotein nitrogen of the blood was 27 mg and the protein 5.9 gm per cent. The van den Bergh was too low to read. The chlorides were equivalent to 107 cc of N/10 sodium chloride. A flat x-ray plate of the abdomen showed an unusual central convexity of the right side of the diaphragm with a horizontal anterior costophrenic angle. The diaphragm moved well with respiration, and there was no evidence of fluid above it or air beneath it. The lung fields were essentially clear, and there was no evidence of varices in the esophagus. The splenic flexure of the colon was unusually high. When the patient was in the upright position, there was a single loop of slightly dilated small bowel in the center of the epigastrium which contained gas and fluid. The colon contained a small amount of barium and showed no evidence of dilatation. Films taken at the hospital where the patient had been before entry here showed an unusually high stomach and a large duodenal loop. A repeat flat film of the abdomen taken the day after entry showed no definite change except that the colon was filled with gas and appeared to be moderately dilated.

On the day following entry the patient experienced rather severe, persisting, epigastric pain which was more severe than any he had had previously and was not relieved by morphine. His abdomen was tense, distended and very tender, with maximum tenderness just above and lateral to the umbilicus. The white-blood-cell count was 18,200.

A laparotomy was performed on that day.

X-RAY INTERPRETATION

DR. AUBREY O. HAMPTON. These upright films of the abdomen were taken on the day of entry and the barium that you see here in the colon was administered before he came in. As the note states, there was no free air beneath the diaphragm and the diaphragm moved well with respiration although it did show this queer central convexity on the right side. We have seen a shadow like this on several occasions and each time we have become excited about it, but it has always turned out to be nothing but an anatomic variation. We gave

barium and ruled out varices in the esophagus. We could not examine the stomach satisfactorily at that time, but at the previous examination done outside the hospital the stomach, duodenum and colon were normal. The upright film shows this single loop of dilated, gas-and-fluid-filled small bowel in the center of the epigastrium. It is the only definite, abnormal finding we saw.

DIFFERENTIAL DIAGNOSIS

DR. FRANKLIN G. BALCH, JR. In reviewing the history, we have a man of sixty-seven who was well until six months before he came into the hospital. The point that strikes us first is that at that time he had epigastric distress relieved by food and soda, which makes us wonder if he had a duodenal ulcer. The x-rays seem to rule that out. Also, if he had an ulcer with a subacute perforation just eleven days before entry he should have been sicker at the time of entry. If he had had a subdiaphragmatic accumulation of fluid he certainly ought to have shown evidence of it in the x-rays. His diaphragm should not have moved freely, and he should not have had normal respiration. Carcinoma of the stomach can also be ruled out on the x-ray findings.

How about the possibility of gall-bladder disease to explain his trouble? I believe that gall-bladder disease could account for the attack of epigastric pain six months before entry with symptoms relieved by food and soda. He was able to go back to work after his episode eleven days before entry, and that too is consistent with such a diagnosis. When he came into the hospital his symptoms were those of obstruction, with a distended abdomen and epigastric pain. I think we can rule out obstruction of the large bowel by the x-ray and by the fact that his pain was entirely epigastric. The symptoms were too intermittent in character for an acute obstruction caused by volvulus or intussusception. He has apparently had obstructive symptoms which have subsided and then recurred.

We have to think of appendicitis but I do not believe that it enters into this picture because he did not have paralytic ileus. He has had no previous operation to suggest the possibility of adhesions. Carcinoma of the small bowel must be considered. It is a rare disease, but it does give intermittent obstruction such as this patient has had. It may last a period of several months or even a year, but if it had been going for as long as six months I should expect the patient to have been more cachectic. He apparently was a fairly well-nourished man.

Some form of mechanical obstruction in the bowel must be thought of. I am probably a little

biased in favor of the possibility of gallstone colic, as I have had occasion to look up some cases here recently. I found only 10 in the hospital records from 1898 to 1932. It occurs in the older age group and is characterized by intermittent symptoms. I believe that the attack six months previously might perfectly well have been a gall-bladder attack and that the episode eleven days before entry was perhaps when the stone ulcerated through into the bowel. It is customary with this type of disease that, as the spasm lets up, the patient may pass gas and fecal material until the stone obstructs again. The stones may or may not show by x-ray. There were 6 cases in this series in which an x-ray was taken, stones showed in 3 of these. The fact that nothing showed up in the x-ray does not necessarily mean that he did not have a foreign body obstruction. I am therefore going to make a diagnosis of mechanical obstruction in the upper small bowel, probably from a gallstone.

CLINICAL DISCUSSION

DR. ARTHUR W. ALLEN This man presented a very interesting diagnostic problem. He had been x-rayed in a hospital in a neighboring city, and the x-ray man had made a diagnosis of carcinoma of the pancreas on the basis that the stomach was pushed up by something, and the patient was sent in here with that diagnosis. We were a little suspicious, however, and did not agree with it. On entry the man was so well that we felt we could watch him for a while and study him a little more, but following the x-ray examination done in this institution he had a recurrent episode of acute abdominal discomfort. The history, so far as it is given, is quite accurate, but it does not really give much idea as to how ill he looked after he had had his second episode of pain. He was in shock and the abdomen was distended and very tender, particularly in the epigastrium, in the left upper quadrant and to the left of the midline. We decided that he had some form of intestinal obstruction. We cast about in our minds for various possibilities as to the diagnosis and I am not clear now why we happened to make the correct one, because it was not so clear as it might sound. However, we operated on him with a preoperative diagnosis of a mesenteric thrombosis. Perhaps it was the extreme illness of the patient that made us feel that that was his trouble. We did find that almost the entire jejunum was gangrenous, but in a different way from what we usually see in mesenteric thrombosis, that is, it had intermingled spots of necrosis and of almost normal-looking bowel over a distance of about 3 or 4 ft. The mesentery of the bowel was tremendously

thickened, and there were a great many enlarged lymph nodes in it. The bowel was greatly dilated and did not have the clear-cut, frankly gangrenous appearance that we see with the usual thrombosis that occurs in the artery. We believed that it was a venous thrombosis, cause unknown. In retrospect, I think that this diagnosis more adequately explains the episode ten days previously. We had to resect the jejunum from just a few inches below the ligament of Treitz for 3 or 4 ft and did an end-to-end anastomosis. Much to our surprise he completely recovered, after a stormy convalescence, and went home.

A PHYSICIAN: How often do you see a white count as low as that with mesenteric thrombosis?

DR ALLEN: I knew someone would speak of that. In any thrombosis that occurs in the artery it is apt to be high (30,000 to 40,000). The count of 18,000 bothered us in making the preoperative diagnosis, but we believed it was not the kind of mesenteric thrombosis that we commonly see. We considered seriously the question of gallstone ileus and were hesitant about ruling it out. It would stand up perfectly well with the story as he gave it.

A PHYSICIAN: Are the x-ray findings characteristic of 4 ft of gangrenous small intestine?

DR HAMPTON: They are not characteristic of anything. A man as sick as he was from any other disease would probably show a little gas in his small bowel. I have no proof, but I think the routine case of mesenteric thrombosis shows very little.

PREOPERATIVE DIAGNOSIS

Mesenteric thrombosis

DR. BALCH'S DIAGNOSIS

Gallstone ileus

ANATOMICAL DIAGNOSES

Thrombosis of superior mesenteric vein
Gangrene of jejunum

PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: The term mesenteric thrombosis as used by clinicians covers three entirely separate types of vascular lesions in the mesentery. The commoner types of vascular occlusion are arterial, these may be divided into those caused by a local thrombosis developing on the basis of atherosclerotic plaques within the mesenteric artery or by an embolus breaking loose from the heart or aorta and swerving down the mesenteric artery. Probably embolus is the commonest etiologic agent. Then there is a third type where the occlusion is on the venous side, sometimes associated with septic phlebitis, other times appar-

ently a bland thrombosis, which was the case here. This specimen showed complete occlusion of the entire venous system up to a point about 10 cm from either margin of the resected gut, where the vessels became patent again. The arteries throughout the specimen were perfectly free of clots. The gut was gangrenous in part but not so completely as one would expect with a ten-day story of arterial occlusion.

A PHYSICIAN: Does a process such as this ever develop into portal thrombosis?

DR MALLORY: There is always that possibility.

DR ALLEN: You have no light to throw on the etiology of this condition?

DR MALLORY: Not the slightest.

A PHYSICIAN: What was the significance of the previous six-month story?

DR MALLORY: One wonders always whether a volvulus or intussusception could be the initiating factor by slowing circulation long enough to let the thrombotic process start, but I have never seen any evidence to prove that such is the case.

CASE 24212

PRESENTATION OF CASE

A twenty-eight-year-old, white, American electrical engineer entered the hospital for treatment of a recurring tumor of the chest wall.

Five and a half years before entry he noticed a lump on one of the ribs of the left side of his back. Part of the rib was removed by his surgeon following which the patient was discharged as well. Two years later he noticed enlargement of the stump of the resected rib and extension of the tumor to the adjacent rib. The remains of the stump and the adjacent rib were resected, and he was sent to a Boston hospital for follow-up treatment. Eight months later the tumor recurred in the operative scar and was again removed surgically. It recurred again twenty-seven months later on the rib stump, and again was resected. Seven months later, one week before entry, an x-ray was taken at another hospital which showed a "questionable area at the base of the right lung." At the time of entry he had no symptoms, and he had always been in excellent health. He had never been exposed to tuberculosis and had never had heart or lung trouble of any kind. He had not lost weight or strength. His family history was noncontributory.

Physical examination revealed a well-developed and nourished man apparently in excellent health. There were healed surgical incisions on the posterolateral aspect of the left chest and questionable slight muscular atrophy in the right subclavicular region. The lungs showed a few rales at the right

base but were otherwise negative. The heart and abdomen were negative, and the blood pressure was 130 systolic, 60 diastolic.

The temperature was 98.6°F, the pulse 88. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 4,460,000 with 80 per cent hemoglobin, and a white-cell count of 6300 with 67 per cent polymorphonuclears, 27 per cent lymphocytes and 6 per cent monocytes.

An x-ray of the chest showed a rounded mass measuring about 4 cm. in diameter which was continuous with the right posterior costophrenic angle at about the posterior axillary line. The costophrenic angle was obliterated, apparently by a small quantity of fluid. The remainder of the right lung was clear. There was a small, in definite, rounded nodule measuring less than 1 cm. in diameter overlying the anterior end of the left fourth rib. The left lung was clear. There were no mediastinal masses, and the rib resected at the previous operations had not regenerated.

An operation was done on the eighth day.

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES: It is interesting that the mass appears on the opposite side from where his previous trouble had been. The mass itself is obviously in the lower portion of the right lower lobe.

DR. RICHARD H. WALLACE: Is there any evidence of calcification?

DR. HOLMES: No. It has a very indefinite margin, and there is a peculiar band above it. It looks more like an infiltrating tumor than a sharply localized, encapsulated lesion.

DR. WALLACE: Can you demonstrate the nodule described at the end of the previously resected rib?

DR. HOLMES: No, I think they must have operated again. The end of the rib is perfectly smooth.

DR. WALLACE: Is there one rib entirely missing?

DR. HOLMES: Yes.

There is no evidence of anything on the left side, and no pleural change. On the right side you have a poorly defined lesion with some fluid in the pleural space. It could be due to a malignant tumor or to an inflammatory process. I do not believe that it could be due to benign tumor.

DIFFERENTIAL DIAGNOSIS

DR. WALLACE: Our problem is one of deciding the nature of the tumor arising in a rib and recurring locally four times over a period of five and a half years, in a young, healthy individual. I suppose we should mention gumma in any tu-

mor of the chest wall, but as there is no evidence of anything in the history or physical findings suggestive of syphilis I believe we can rule that out. I do not believe that any tumor that has recurred four times after surgical removal without a breaking down of the skin or without sinus formation can be tuberculous. Lymphosarcoma does occur in ribs, but lymphosarcoma of five years' duration would not leave so healthy an individual. Myeloma more commonly occurs in the older age group—the fourth or fifth decade, it is almost always a multiple tumor, and after five years the disease should be generally apparent. Giant-cell tumor of the rib is extremely rare. There is one case from this hospital in the Warren Museum, but I do not know of any other from this city. The few cases in the literature occurred at the end of the rib and presumably this had its origin in the midportion. Ewing's tumor occurs at this age. It does occur in ribs, but there is usually a history of trauma and almost always a story of pain, temperature and elevated white count. It is more likely to be confused with osteomyelitis, and often, even at operation, the differentiation of a Ewing's tumor and osteomyelitis is extremely difficult.

A tumor arising in the rib and recurring four times after local excision in a healthy young individual is most likely a chondroma or an osteochondroma. This type of tumor with time, and possibly with the trauma of multiple operations, is very likely to become malignant. It is the type of tumor that is likely to metastasize to the lung, and not infrequently the early metastases are solitary. I suppose this evidence of a lesion in the lung may have nothing to do with the original tumor, but I believe that this is probably a chondroma or an osteochondroma which has become malignant and has metastasized to the lung.

CLINICAL DISCUSSION

DR. CHANNING C. SIMMONS: I sent this young man into the hospital. The first four operations were done elsewhere. I did the last one, removing the entire rib. That is why Dr. Holmes cannot see the rib. The patient had routine x-ray films of the chest every three months, and the lesion in the lung was found. On reviewing the plate taken three months earlier one can see the same area very indistinctly, but it was not recognized at the time.

DR. EDWARD D. CHURCHILL: This is another tragic story of a chondrosarcoma of the rib originally treated by inadequate excision. These tumors are often spoken of as "benign." I consider them to be among the most treacherous tumors of the chest wall, and from our experience here, they must be treated as malignant tumors and the entire

rib in which they are situated must be removed at the first operation. The mistake is often made, or has been made in the past, that the surgeon tries to remove the tumor without opening the pleural cavity and with a margin of only 2 or 3 cm of the rib. We know that this is not adequate surgery, and the surgical results for this type of tumor, as reported in the literature, are notoriously bad. In this case we were presented with the diagnosis from the previous examinations, and the only question was whether it was worthwhile removing a metastasis. In this particular type of tumor I think it is justifiable to try to keep abreast with the metastases and the recurrences once they have started. So we did remove the lower lobe of the lung, a piece of the diaphragm that came in contact with the metastasis, and a section of the parietal pleura. I think the tumor will recur, but at least the operation has given him another span of a year or a few years until the recurrence takes place. I spoke of it as a tragic case, but the man had very little reaction to operation and was discharged from the hospital perfectly well.

A PHYSICIAN Was there any sign of local recurrence?

DR. CHURCHILL We did not explore that side.

DR. SIMMONS I agree with Dr. Churchill's remarks but should not want to limit them to chondromas of the rib, for I believe they apply to similar tumors of the other bones. I recall a case of a man of thirty-six, who in 1913 presented a chondroma of a metatarsal. A portion of the bone was removed and the tumor reported to be nonmalignant. Thirteen years later he returned with a recurrence, and the foot was amputated. He died a year later with lung metastases. In another case with multiple exostoses, Dr. Hugh Cabot performed a shoulder-joint amputation for sarcoma in 1902. In 1918 the femur was amputated for chondrosarcoma. Five years later the other femur was amputated, and he died three years later of acute appendicitis. This is not unusual in osteochondromas. The same thing happens in the os-

teochondromas of the pelvis, which are usually inoperable.

PREOPERATIVE DIAGNOSIS

Metastatic sarcoma of rib

DR. WALLACE'S DIAGNOSIS

Osteochondrosarcoma with metastasis to lung

ANATOMICAL DIAGNOSIS

Osteogenic sarcoma, chondroblastic type

PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY It is difficult to know where to pin the responsibility for the improper treatment that these patients receive in most instances. Unquestionably both pathologists and surgeons are to blame, but I think that the trouble primarily is the failure of the pathologists and surgeons to understand each other. These chondromas of the ribs appear, from the histological point of view, as very benign tumors. It is almost impossible for the histologists looking at sections to imagine that they can be malignant and can metastasize. As a matter of fact, the majority do not metastasize in this initial stage of the disease. They have, however, an extreme tendency to implantation. It seems very probable that a single tumor cell implanted in a wound will give a recurrence, and I do not know of any other tumor in which implantation occurs with such frequency and regularity. Eventually, in the course of successive recurrences, frank malignancy may develop. In this case, inasmuch as the tumor found on the last entry was in the lung on the opposite side from where the original rib had been removed, there can be no question that we are dealing with a metastasis. The sections of the mass show a frankly malignant tumor, in part spindle-celled, in a few places showing a small amount of osteoid formation, we can call it osteogenic sarcoma in its present form.

Communications should be addressed to the NEW ENGLAND JOURNAL OF MEDICINE, 5 FENNER HOUSE, BOSTON, MASS.

ATTEND THE ANNUAL MEETING!

The advance program of the annual meeting of the Massachusetts Medical Society has been sent to the fellows: the amended program was published in the *Journal* of last week. This document, the culmination of months of effort, warrants careful study as it offers to members a well-considered selection of entertainment as well as a résumé of much that is of importance in the progress of modern medicine.

Upon arrival at the Hotel Bradford, fellows will find adequate facilities for free parking. (Be sure to remove the green-cross sticker from your advance program and put it on your automobile windshield!)

The scientific exhibits located on the balcony of the Ballroom, offer sixteen different demonstra-

tions in the various fields of surgery, medicine, pathology, public health and radiology.

You are strongly urged to attend and examine the commercial exhibits. The annual meeting is an expensive affair. Fortunately for the Society, the cost does not fall entirely upon its members; if it did the meetings in their present form would be a luxury it could ill afford. The various manufacturers of drugs, medicines and equipment and the purveyors of services pertaining to the medical profession have found it worth while in certain instances to present their wares in the form of exhibits. These in many cases are extremely interesting, featuring displays of the newest articles as well as of time-tested products. It is well worth the members' time to examine each and every one. Most of our exhibits belong to the Medical Exhibitors Association. This organization keeps systematic records of the hundreds of medical meetings that are held throughout the country each year, and on the basis of its analysis is based the decision as to which meetings its members should attend. A good rating with their association is desirable, and can be obtained if fellows will register at the various booths. Our standing has not always been of the best. Possibly our New England attitude of indifference has kept us from showing more interest in these displays. We believe that a visit to each of the commercial booths will not only repay the physician but be a great aid toward making prosperous meetings in the future.

The combined clinical meeting proved to be a great success at its annual appearance in 1957. It should command even greater attention this year for it not only offers subjects of practical and general interest to all branches of the profession in one continuous meeting but presents papers or clinics by members of the staffs of twelve Boston hospitals—an increase by two over last year. Study of the past programs of other medical societies discloses the fact that this type of meeting is gaining increasing popularity throughout the country. In our own society, the members must soon express their opinion for the guidance of the Committee of Arrangements as to the role of

rib in which they are situated must be removed at the first operation. The mistake is often made, or has been made in the past, that the surgeon tries to remove the tumor without opening the pleural cavity and with a margin of only 2 or 3 cm of the rib. We know that this is not adequate surgery, and the surgical results for this type of tumor, as reported in the literature, are notoriously bad. In this case we were presented with the diagnosis from the previous examinations, and the only question was whether it was worthwhile removing a metastasis. In this particular type of tumor I think it is justifiable to try to keep abreast with the metastases and the recurrences once they have started. So we did remove the lower lobe of the lung, a piece of the diaphragm that came in contact with the metastasis, and a section of the parietal pleura. I think the tumor will recur, but at least the operation has given him another span of a year or a few years until the recurrence takes place. I spoke of it as a tragic case, but the man had very little reaction to operation and was discharged from the hospital perfectly well.

In this case, inasmuch as the tumor found on the last entry was in the lung on the opposite side from where the original rib had been removed, there can be no question that we are dealing with a metastasis. The sections of the mass show a frankly malignant tumor, in part spindle-celled, in a few places showing a small amount of osteoid formation, we can call it osteogenic sarcoma in its present form.

world as a model and its catalogue, first published in 1879 and issued ever since that date, has been described as "America's greatest gift to medicine. Rare must be the physician in this country who pretends in any way to keep abreast of medical thought, who, in some way, does not come in contact with this great institution. The Army Medical Museum, which is closely associated with the library, preserves for the benefit of physicians the largest pathological collection in America. Seven registries of pathology have been established at the museum by national scientific societies since the World War. The Army Medical Library and Museum, therefore, offer a unique opportunity to investigators to study the entire literature on a medical subject and then to view the pathological specimens, gross and microscopic, of the subject under consideration.

It will be a great pleasure for physicians to learn that the President of the United States has approved the project of constructing a suitable building to house these priceless collections and that a bill is before Congress proposing the construction of such a building in Washington. For the first time, therefore, a project which has long been in the minds of many of our leading physicians now has a definite plan. This proposal should receive the hearty endorsement of the medical profession and a letter to the congressional representative of any physician, urging the passage of this bill during the present session of Congress, if written promptly, would serve to emphasize our desire to see the Army Medical Library and Museum properly housed.

MASSACHUSETTS MEDICAL SOCIETY

SUGGESTED REVISION OF BY-LAWS

The majority of the committee appointed by the Council at its meeting on February 2, 1938, to consider suitable changes in the by-laws designed to clarify the method by which delegates to the annual meeting of the American Medical Association shall be chosen wishes to make it clear that nothing in its recommended amendment of Chapter IV, Section 7, as printed in the notice

recently mailed to all fellows of the Society, precludes nominations from the floor.

CASE HISTORY No. 73 SEPARATION OF THE PLACENTA

A twenty-two-year-old primipara, due August 23, 1931, entered the hospital August 10, with a history of having had intermittent uterine contractions throughout the day of entry, with the onset of vaginal bleeding one hour prior to entry. At this time the uterine pain became more severe and continuous. The patient was unable to estimate the amount of blood she had lost.

There was no family history recorded, and the patient's past history was not remarkable. Catamenia began at fourteen, had a twenty-eight-day cycle, were regular and lasted four to five days, there was no pain. Her last period was November 16, 1930.

Her antepartum course had been uneventful. She had been followed four and a half months in the prenatal clinic, and at no time had shown hypertension or albuminuria, for the three or four days prior to entry she had felt "nervous." The last visit to the clinic was six days prior to entry.

On physical examination at entry, the patient was a well-developed and nourished woman, crying with pain and apparently very uncomfortable. The skin and mucous membranes were very pale. The blood pressure was 96 systolic, 90 diastolic, with a pulse of 120, which was easily compressible and difficult to obtain. Abdominal examination revealed an eight-months-pregnant uterus, which was tense and rigid. The fetal heart was not heard. A perineal pad worn on admission was soaked with bright-red blood. Vaginal examination revealed the cervix to be partially taken up, the os one finger dilated, and the head in the midpelvis. Thirty cubic centimeters of urine obtained on admission showed a trace of albumin and a few white blood cells.

One-half hour after entry the cervix and vagina were tightly packed with 9 yd. of gauze, following which a Spanish windlass was applied. One minim of pituitary extract was given following these procedures. Intravenous fluids were also started, and

A series of selected case histories by members of the section will be published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the section.

the combined clinical meeting in the annual sessions. Shall it be enlarged in scope to extend through two days, thereby cutting down upon the length of the programs of the various section meetings? Or shall it be rearranged to absorb the section meetings—the latter to be run in tandem with short periods for executive sessions and the election of officers? It is hoped that these possibilities, with perhaps other suggestions, will be considered and discussed in the coming section meetings.

In the matter of guest speakers, the Society is indeed fortunate. Dr. David Riesman, of Philadelphia, emeritus professor of clinical medicine and professor of the history of medicine at the University of Pennsylvania School of Medicine, will give the Shattuck Lecture. His subject is "America's Contribution to Nosography." On the same evening, Surgeon General Thomas Parran, of Washington, District of Columbia, will talk on the work and aims of the United States Public Health Service. For the annual dinner, President Frothingham has been able to secure Mr. Norman MacDonald, executive director of the Massachusetts Federation of Taxpayers' Associations, who will take as his subject, "Tax Problems in Massachusetts: the Obligation of Citizens, Professional and Otherwise, to Do Something about It." We know of no one better qualified to present this interesting and important problem. All who went to the Springfield meeting two years ago will remember with pleasure Dr. Allen S. Rice, visiting surgeon at the Springfield Hospital. He will present the annual oration—a discourse on "The Passing of Surgical Yeomen."

The Ladies' Committee has completed its interesting program for the wives of members. An original feature will be a private dinner party given on the first evening at the Hofbrau House, where our Teutonic hosts will entertain their guests with German songs and dances. Those who have not already done so are urged to send in their acceptances immediately, for the number of tickets is limited.

No one should attend the annual meeting without making at least one visit to the exhibition of

the Boston Physicians' Art Society. It will be stimulating to discover what remarkable work one's busy contemporaries are doing with the spare time which the rest of us find so difficult to turn into creative channels.

Special attention is again called to the golf tournament to be held on Wednesday afternoon, June 1, at the Commonwealth Country Club, 91 Algonquin Road, Newton Centre. Members both with and without club or state handicaps will have their respective divisions and will find an added attraction in the numerous prizes in each group. The Massachusetts Medical Society Golf Challenge Cup, a ten-inch, sterling-silver, Paul Revere bowl, will be awarded for the low net score. Each player should have every inducement to attempt to win this bowl three different years, for this is necessary to make it a permanent part of one's display of trophies. It is hoped that the golf tournament will become an increasingly popular fixture in our spring sessions. Send in your entry now and bring your clubs with you!

Students of the progress of our society, the oldest in continuous operation in the United States, will observe that, year by year, its annual gatherings offer more and more to its fellows. There is every reason to believe that the coming annual meeting will surpass its predecessors in the fields of interest, instruction and entertainment. One must keep in mind, however, that the success of any such venture depends not alone upon the physical equipment but in even larger measure upon the enthusiasm of the members themselves. This enthusiasm is exemplified by a large attendance.

NEW BUILDING FOR THE ARMY MEDICAL LIBRARY AND MUSEUM

THE affairs of the Army Medical Library, which has recently celebrated its centenary, having been established by the Surgeon General of the Army in 1836, are of interest to all physicians. The largest medical library in the world, with its material, except for the rarest books and manuscripts, available to every practicing physician, this library is regarded everywhere throughout the

The cause of death in this disease is due to paralysis of the muscles of respiration. Many lives have been saved, however, in the last few years by the use of respirators. This is a machine devised to keep up artificial breathing indefinitely. Some patients have been kept alive for months by the use of this machine, and then gradually they are able to breathe properly without it.

The treatment after the acute stage is of extreme importance and has two objects, first, to prevent the development of the deformities which are liable to occur and secondly, to bring back power to the paralyzed or weakened muscles. Most of the deformities may be prevented if the patients come under treatment immediately after the onset. This means the application of light splints or plasters to hold the limbs in their normal positions to prevent the contraction of normal muscles when unopposed by the weakened ones.

The bringing back of power to muscles weakened by this disease is a long and tedious process. In the case of certain muscles, where the nerve centers have been completely destroyed, no power can ever be regained. A great deal of improvement can be made, however, in weakened muscles where the nerve supply is only partially destroyed. By prolonged treatment many muscles make a complete recovery of their powers to function.

An important aid to muscle training, which is usually given on an examination table, is what is called under water treatment, or treatment in a tank or pool. Under water treatment is a very pleasant way of carrying out the prescribed muscle exercises. The buoyancy of the water allows the patients to carry out movements more easily than on a table without the aid of water. In this treatment very carefully supervised exercises must be given, and it must be borne in mind that it does not consist merely of putting the patient in the water simply to swim and splash around. The patients must be carefully watched so that they will not overuse the stronger muscles and increase any deformity already present.

Parents should see to it that in the early stages their children receive proper attention and are not neglected until deformity occurs. It is much easier to prevent an early deformity than to correct it later. We see many patients with terrible deformities, the legs drawn up to the body, with bad curves of the spine, and some even crawling about on all fours, due really to neglect, the parents believing that nothing can be done for these pitiable children. Patients paralyzed for many years can be greatly benefited by proper treatment. The idea that nothing can be done for cripples of long standing is entirely wrong.

As the treatment for this disease is such a slow one, parents are apt to become discouraged. They will be advised to do this or that, and will receive pamphlets from charlatans promising cures. There is no quick cure, and no honest physician can or will promise one.

Based on the observation of over 6200 cases of infantile paralysis, it can be said (1) between 35 and 40 per cent of all cases become normal, (2) deformities can and should be prevented by proper treatment, (3) practically every case can be made to walk, although some will require braces and crutches, and (4) with proper treatment and suitable vocational training, no victim of infantile paralysis should become a public charge.

Q How is this disease contracted?

A. The disease is caused by a kind of germ which is called a filterable virus. This is apparently spread by ordinary contact, probably in much the same manner as the virus of measles. Only a very small minority of those who are exposed to the virus develop symptoms character-

istic of the disease. Whether or not paralysis develops may depend upon the inherent resistance of the individual to the virus. But the nature of these factors of resistance is yet unknown.

Q How much permanent paralysis will my child have?

A. About 50 per cent of patients who develop the characteristic early symptoms do not develop paralysis at all, and about 50 per cent of those who develop paralysis recover entirely. None of the symptoms in the early stage of the disease make possible a prediction as to the amount of permanent paralysis. This depends on the amount and degree of nerve-cell impairment in the acute stage of the disease.

Q After the disease has started, is there anything to be done that can prevent later paralysis?

A. That is what we are trying to find out by research. We are hoping to discover some means of stopping the action of the virus before it has injured the nerve cells.

Q How can deformities be prevented?

A. By early treatment of the affected muscles. This is accomplished by the application of light splints or plasters to the affected parts to keep them in their normal positions, followed later—when sensitiveness has subsided—by muscle re-education.

Q When a child's leg muscles are affected, why not let him run around for his exercises?

A. Because by doing this he will tire the already weakened muscles and strengthen the normal ones, thus causing deformities.

Q Why do you operate on these cases?

A. To correct existing deformities, to change unstable joints into stable ones, and to transplant strong tendons or muscles to take up the work of the paralyzed or weakened ones in order to give the patient a better balance of muscle power.

NEW HAMPSHIRE MEDICAL SOCIETY

HISTORICAL

The records of the New Hampshire Medical Society, dealing with each annual meeting, contain much that is of interest to the student of New Hampshire medicine. In 1827, for instance, we are told that Drs. Thomas Chadbourne and Josiah Crosby resigned because the Society did not enforce the regulation relating to consultation with irregular practitioners. After listening to a report on the subject by Dr. Oliver, those present refused to accept the resignations, because the petition contained unproved charges against the Society and certain particular members. The report contains a remarkably able and cogent argument against leaving an organization to reform alleged irregularities in it.

At this same meeting a dissertation on fractures, presented by Dr. Luke Howe, was nearly completed when the landlord appeared and notified the Society to find accommodations elsewhere. It was adjourned to the court house. This summary conduct on the part of the host is thought to have been due, though the record is silent on this point, to the uncompromising attitude of the Society on the use of alcohol.

BOARD OF REGISTRATION IN MEDICINE

A special meeting of the New Hampshire Board of Registration in Medicine, for the licensing of candidates

soon thereafter she began to bleed through the vaginal pack. Two transfusions of 500 cc of citrated blood were given, because of a rapid, poor pulse of 132, air hunger, thirst and other evidences of blood loss, although the blood pressure was 150 systolic, 130 diastolic. Vaginal bleeding stopped after the second transfusion. Pituitary extract was continued in increasing doses up to 4 min every half hour. Restlessness was controlled by two doses of morphine (1/4 and 1/6 gr). The patient went into labor about three hours later and gradually pushed out the vaginal pack. Eleven and a half hours after entry, under gas-oxygen anesthesia, she was delivered normally of a dead, but not macerated, full term, male infant. The blood loss at delivery was 325 cc.

At delivery only 30 cc of urine was obtained, which also showed a trace of albumin. Because of the oliguria the patient was put on constant drainage so as to follow the urinary output more accurately. Immediately after delivery the patient was given 150 gm of glucose in 500 cc of saline, in an attempt to stimulate urinary output.

Following delivery the patient's condition was improved. There is no record of the blood pressure immediately after delivery, but at the end of the day it was 100 systolic, 76 diastolic. During the puerperium the urinary output increased, the amount of albumin decreased, and the blood pressure gradually fell to normal, being 110 systolic, 86 diastolic, at discharge.

Blood studies on August 12 showed a nonprotein nitrogen of 50 mg, a urea nitrogen of 22.5 mg and a uric acid of 70 mg per cent. These values all decreased during the puerperium. On August 15 the nonprotein nitrogen was 32 mg and the uric acid 51 mg per cent, and on August 22 they were 48 mg and 5.3 mg respectively. The postpartum course was uneventful, and she was discharged well on the fourteenth day.

The placenta weighed 320 gm. There was a 2-cm area of old hemorrhage into the placenta with resultant necrosis of the surrounding tissue, including the associated decidua, over an area 9 by 4 cm. The old necrosis of the decidua had resulted in a massive, recent hemorrhage covering half the maternal surface of the placenta to a depth of 1 to 4 cm. The latter was the pathologic lesion associated with the vaginal bleeding on entrance, but the older hemorrhage causing the infarction, which in turn was responsible for the recent hemorrhage, occurred some days prior to the onset of the patient's acute illness.

Comment. This is a typical history of toxic separation of a normally situated placenta and shows how quickly separation can take place. She visited the clinic six days prior to entry and was

normal in all respects. The success of the conservative treatment for this condition is again evidenced. When the baby is dead and when the patient is in shock it is almost never advisable to do anything but treat the case in this conservative manner. The quick recovery to normal of blood constituents, urine and blood pressure points to a complete recovery. Time alone, however, will prove whether lasting kidney damage exists.

INFANTILE PARALYSIS

The victims of poliomyelitis, more commonly called infantile paralysis, are a common sight to us all.

Not many years ago the very mention of the name, infantile paralysis, struck terror to the hearts of parents. This fear that their children may catch the disease still exists, but parents today need not have the dread that their children, so afflicted, will become hopeless cripples, a constant care or a great expense to themselves or the community.

If the disease is recognized early and if prompt and effective treatment be given, none of the terrible deformities we have been accustomed to see need occur. It is only by the early prevention of beginning deformities that this may be brought about.

Infantile paralysis is caused by an infection which damages that part of the spinal cord containing the nerve cells which control muscles in all parts of the body and which make them contract and thus produce movement. This damage may weaken or completely paralyze the muscles affected.

The disease is most common in children under twelve, but persons of all ages may be affected. The majority of cases occur in late summer or early fall, generally from August to November, but cases are reported throughout the year.

The symptoms at the onset vary a great deal. At the beginning the child perhaps may not be so active or want to play with other children. He may complain of a sore throat, a mild digestive upset, or pain in the abdomen, legs or arms. He is very sure to have a slight rise in temperature and to complain of headache, and will be found unwilling to bend forward to put his head between his knees, on account of stiffness of the neck and back. It is most important for parents whose children show any of these symptoms, especially stiffness of the neck or back, to consult their family physician at once. If he suspects infantile paralysis, the Massachusetts Department of Public Health will always send a doctor to verify the diagnosis.

The paralysis or weakness takes place generally in from twenty-four to forty-eight hours after the first symptoms are noticed. At this time, or as early as the first symptoms are seen, pain of varying severity is usually present in the arms or legs and sometimes in both.

You have seen a great deal in the papers about the use of serum in the treatment of infantile paralysis to lessen or prevent the paralysis. The use of serum was based on experimental evidence that serum of patients who had recovered from the disease, called immune serum, would destroy the germ in other patients. While a few years ago we were very hopeful that this procedure might be of great help in the treatment, we have, I am sorry to say, no proof that it is of any benefit.

A Green Light to Health broadcast given by Dr. Arthur T. Legg on Wednesday May 11 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

moving frequently Tuberculosis is their major health hazard. While the white tuberculosis death rate in Hartford has been declining, that of Negroes has remained as high as it was twenty years ago Syphilis is a leading cause of illness and death and is one of the major causes of heart disease. The heart-disease death rate of Negroes in Hartford during 1937 was almost double that of the white population. The infant mortality rate in Negroes was over two and a half times that of the white population.

ADDITION TO UNDERCLIFF SANATORIUM

Plans have been made public for a new \$600,000 infirmary, school and administration building of brick and concrete for Undercliff Tuberculosis Sanatorium at Meriden. The new structure will provide a 200-bed infirmary with expansion room on porches, modern facilities for children from three months to eighteen years old and equipment which will make it one of the finest in the country. The building has been designed to conform with the modern needs of tuberculosis sanatoriums.

HARTFORD COUNTY MEDICAL ASSOCIATION

Dr James R. Miller has been elected president of the Hartford County Medical Association succeeding Dr Maurice T. Root. Dr Henry Costello, Hartford's medical examiner, has been elected vice president, Dr Frank T. Oberg re-elected secretary treasurer and Dr Root made a member of the Board of Censors. Dr Benjamin Robbins has been elected to membership on the Committee on Public Policy and Legislation. New state delegates who are also members of the Board of Directors, are Dr James M. Lynch, Dr Peter J. Steincrohn, Dr Edwin C. Higgins, Dr Aaron P. Pratt and Dr Charles T. Schechtman.

Dr Root's address as retiring president was entitled "An Everyday Approach to Some Pressing Medical Problems." The guest speaker, Dr Charles H. Goodrich, president of the Medical Society of the State of New York, discussed "Public Health and Preventive Medicine in Private Practice."

CONSTRUCTION AT FAIRFIELD STATE HOSPITAL

Plans have been announced for two continued treatment buildings for the Fairfield State Hospital at Newtown, each building to have a rated patient capacity of 420. In the previous building program of the institution a Reception Hospital for the treatment of early acute cases was provided; there was also constructed a General Hospital for the care of the strictly medical and surgical cases. The units now to be constructed, one for either sex, are for the care of well-adjusted patients requiring prolonged or indefinite hospitalization, but who, in general, are able bodied and require, in relation to other patients, a lesser amount of medical, psychiatric and nursing care.

MEDICAL INFORMATION BUREAU MEETING

On April 13 at a meeting in Hartford sponsored by the Medical Information Bureau, Dr Herman Lande, of Mt. Sinai Hospital, New York, presented the plan for a paid diagnostic clinic as it now operates in New York City. The clinic was established in 1930, is maintained for the benefit of persons whose combined family income is not above \$4000 annually, and returns to the staff physicians half the payments received. The clinic is now taxed to its capacity.

NEW ENGLAND SOCIETY OF PSYCHIATRY

The New England Society of Psychiatry held its annual meeting April 26 at the Neuro-Psychiatric Institute of the Hartford Retreat. Dr Louis H. Cohen, of the Research Service, Worcester State Hospital, gave the principal paper on "The Treatment of Schizophrenia with Metrazol." Dr Harlan L. Paine, of the Grafton (Massachusetts) State Hospital, was elected president of the society. The meeting was well attended by prominent psychiatrists from New England, New York and the District of Columbia.

CONNECTICUT SOCIETY FOR MENTAL HYGIENE

The thirtieth anniversary of the Connecticut Society for Mental Hygiene, originator of activities that have become national and international, was celebrated in New Haven on May 5 and 6. The program included a founders dinner at the Faculty Club, formerly the home of Prof. Anson P. Stokes, where the society was formed.

DEATHS

SELLECK—NATHANIEL SELLECK, M.D., for twenty years president of the Danbury Board of Education, died in that city on March 13. Dr Selleck was born in Danbury, November 2, 1868, and had been a lifelong resident of that place. He was graduated from the Medical Division of the University of the City of New York in 1891, and went to Danbury where he had practiced until his final illness. He was prominent in community affairs and was actively interested in politics. On more than one occasion he was considered as Democratic nominee for mayor, but always declined. He was a member of the staff of the Danbury Hospital and senior member of the medical staff. He was a member of the Danbury Medical Society and the Fairfield County Medical Association. He was a 32nd degree Mason, and also a member of Pyramid Temple, Mystic Shrine, and of Danbury Lodge of Elks. He is survived by his widow, a son, Dr. Nathaniel B. Selleck, and two grandsons.

ELLIOTT—CALVIN H. ELLIOTT, M.D., of Hartford, died March 15 in Tucson, Arizona, where he had been staying since late in December. Dr Elliott had been a member of the Hartford Hospital staff since 1916 and was consulting gynecologist and obstetrician for many hospitals around Hartford. He was a graduate of Bucknell University and of Jefferson Medical School. About fifteen years ago Dr Elliott received a life saving medal from the American Red Cross for a daring piece of rescue work accomplished at North Truro, Massachusetts. He was a member of the American and Hartford County medical associations, the Hartford and Connecticut State medical societies and the New England Obstetrical and Gynecological Society. He was also a fellow of the American College of Surgeons and a member of the Wadsworth Atheneum, the Hartford Golf Club, Sphinx Temple, Mystic Shrine, and the Hartford Rotary Club. He is survived by his widow, a daughter, Marie Luise, and a son, Calvin H., Jr.

NETTLETON—FRANCIS I. NETTLETON, M.D., health officer and former mayor of Shelton for ten years, died March 19, after an illness dating from last November. A native of Shelton, he was born October 23, 1874, the son of Charles O. and Frances Hallock Nettleton. He was graduated from the Sheffield School of Science in 1894, then entered Yale School of Medicine and was graduated in

by examination and by reciprocity, will be held at the State House, Concord, at 10 a. m. on June 15 and 16. Candidates should apply to the secretary, Dr. Fred E. Clow, Brown House, Wolfeboro.

SOCIETY MEETINGS

Dr. Dwight O'Hara, assistant dean of Tufts College Medical School, was the guest speaker at the Dover Medical Society on May 5. His subject was "Scarlet Fever and Streptococci."

A meeting of the Strafford County Medical Society was held at Rochester on April 27. Drs. Roscoe G. Blanchard, Louis W. Flanders, John H. Bates and Forrest L. Keay, active members of many years standing, were made honorary members of the society. Dr. Andrew J. Oberlander, Durham, University of New Hampshire medical director, was elected to membership. Dr. Samuel F. Marshall, of Boston, read a paper entitled "The Acute Abdomen."

A combined session of the Hillsboro County Medical Society and the New Hampshire Surgical Club in its forty-first annual convention was held at Nashua on April 26. Operative clinics were conducted by Drs. Halsey B. Loder, George Smith, Gordon M. Morrison and Frank H. Baehr. Drs. Ezra Jones, Harold G. Lee and George Smith participated in a symposium on "Low-Back Pain," after the business meeting at the Nashua Country Club.

Hon. Frank J. Sulloway and Drs. Sven Gundersen and E. L. Levine took part in the program at the recent annual meeting of the Rockingham County Medical Society at Portsmouth. Dr. Ralph Barker presided at the sessions. Dr. James Sanders illustrated his talk on "Traumatic Injuries of the Extremities" with moving pictures.

A meeting of the Belknap County Medical Society was held at the New Hampton School on April 5. Dr. M. Alice Normandin presided and the guest speaker, Dr. Halsey B. Loder, of Boston, read a paper entitled "Emergency Treatment of Conditions That Arise in General Practice."

DEATHS

BADGER—MELVIN P. BADGER, M.D., of Manchester, died Saturday, April 23, at the age of fifty-one. During the World War he served for two years in France as a captain in the Medical Corps. He was prominent in the veterans organizations of Manchester and a member of the medical staff of the Notre Dame Hospital.

He is survived by a son, Melvin E. Badger, of Manchester, and two sisters, Mrs. Martha A. Smith and Mrs. Libbie M. Cummings, both of Boston.

DRAKE—CHARLES B. DRAKE, M.D., died from pneumonia at his home in West Lebanon on April 2. He was born in St. Johnsbury, Vermont, on August 19, 1848, to Spencer and Abigail (Keith) Drake. For fifty years he had been in active practice in West Lebanon and vicinity, retiring several years ago because of ill health.

He had served on the Board of Education and the State Board of Health and represented the town of Lebanon in the New Hampshire General Court for more than six terms. He had also been school physician in West Lebanon. In 1933 he was honored by the New Hampshire Medical Society for his fifty years of active practice.

PERSONALS

Dr. Benjamin W. Baker, superintendent of the Laconia State School, was a delegate to the meeting of the American Association on Mental Deficiency at Richmond, Virginia, the last week of April. Dr. Baker led a discussion of the relation of mental deficiency to medicine and presided over a session of the convention. He is a member of the Public Relations Committee and of the Nominating Committee.

Certificates of the American Board of Internal Medicine have been granted to Drs. Fred E. Clow, of Wolfeboro, and Robert B. Kerr, of Manchester.

Dr. Frank S. Lovering, Moultonboro, who was ill for several weeks, has resumed practice.

Dr. W. J. Paul Dye has returned from a recent vacation in West Virginia.

Dr. Kenneth E. Dore, formerly of New Hampshire, has opened an office for the practice of medicine at Fryeburg, Maine.

NOTE

Mrs. Harry Almond, of Rochester, was elected president of the Women's Auxiliary to the Strafford County Medical Society. At its recent meeting Dr. L. W. Flanders was the guest speaker. Other officers elected were Mrs. Harold Adams, of Somersworth, vice president, Mrs. Louis Collin, of Dover, secretary, Mrs. Joseph MacLaughlin, of Farmington, treasurer, and Mrs. J. J. Morin, of Rochester, auditor. Mrs. J. J. Topham, president of the state organization, was a guest.

MISCELLANY

CONNECTICUT NEWS

MORTALITY IN CONNECTICUT FOR THE PERIOD, 1933-1937

The year 1937 established a record low death rate of 9.9 per 1000 population of Connecticut residents dying within the borders of the State. Records were made during the five-year period by an infant mortality rate of 40.5 per 1000 live births, by a rate for all forms of tuberculosis of 36.8 per 100,000, by one of 1.6 per 100,000 for diarrhea under two years of age, and by a maternal mortality rate of 2.9 per 1000 living births.

CLINICS FOR CRIPPLED CHILDREN

Diagnostic clinics for crippled children have been started at each of the five centers in the State. Eighty-four patients were examined at the five clinics, half of them being nine years of age or under. Sixty-eight of the 84 were found to be eligible for care by the Division of Crippled Children, State Department of Health.

NEGRO HEALTH PROBLEMS IN HARTFORD

By increasing the Board of Health budget from \$97,360 to \$131,040 for the fiscal year beginning April 1, 1937, and by the addition of state funds it has been possible to reorganize the activities of the Board of Health and give special consideration to negro health problems. The average length of life of Hartford's white residents is approximately sixteen years longer than that of the negro residents. The 1937 white death rate was 9.77 per 100,000, while that of Negroes was 17.41. The Negroes do not take advantage of the health facilities now available, many are transients,

Lobar pneumonia, pulmonary tuberculosis, mumps and tuberculosis (other forms) were reported above the five year average.

The incidence of diphtheria was considerably below the five year average.

Typhoid fever continued to show low incidence

The incidences of German measles, measles, whooping cough and meningococcus meningitis were below the five year average.

Paratyphoid fever continued to be reported from several points throughout the State.

The incidence of undulant fever was not remarkable

The reported incidence of dog bite showed a considerable increase since last month. Several cases of animal rabies were reported throughout the State. A new focus was noted in Worcester. Older foci in Cambridge, Rowley and Stoughton were active.

NEW FILM ON TUBERCULOSIS

Four authorities on tuberculosis do the talking in the National Tuberculosis Association's new medical film "Diagnostic Procedure in Tuberculosis," which will be released early in the summer.

The film, which lasts twenty five minutes will be shown by local tuberculosis associations throughout the United States before medical and health groups. It is the first movie of its kind in sound produced by the National Tuberculosis Association.

The doctors who participate in the film are Dr. Kendall Emerson, managing director of the National Tuberculosis Association, New York City, Dr. Ralph S. Muckenfuss, director of the Bureau of Laboratories, New York City Department of Health, Dr. Esmond R. Long, director of the Henry Phipps Institute, Philadelphia, and Dr. Edgar Mayer, assistant professor of medicine, Cornell University Medical College, New York.

Dr. Emerson is the narrator and in his introductory remarks says: "In the front line of the fight against tuberculosis is the general practitioner. He sees the patient first and upon his skill and judgment depends the patient's future. The greatest service he can render is to make the diagnosis correctly and without delay. There are certain diagnostic procedures every general practitioner is capable of carrying out. Dr. Emerson then introduces the speakers."

Dr. Muckenfuss demonstrates a simple technic of sputum examination. The making and reading of the tuberculin test are explained by Dr. Long. Dr. Mayer explains the x-ray as a means of diagnosing tuberculosis and the fundamental facts of x-ray interpretation.

ANNUAL PRIZE SUBSCRIPTION

The annual prize subscription offered by the *New England Journal of Medicine* for the best undergraduate contribution to the *Tufts College Medical Journal* has been awarded for the current year to Bromislaus A. Guluska, M. 39. His paper "Trichinosis" was published in the January, 1938, issue.

NOTE

At the recent annual meeting of the Harvey Cushing Society in Memphis, Tennessee, Dr. Louise Eisenhardt, of New Haven, was elected president and Dr. William J. German, of New Haven, secretary. The next annual meet-

CORRESPONDENCE

PUBLIC-HEALTH ADMINISTRATION

To the Editor: In view of recent events at the State House, it may be of interest to recall some of the things leading to the reorganization of the old Board of Health into the present Department of Public Health.

The late Edward F. McSweeney was the first active factor in the change. In his work at Ellis Island, he had come in contact with men of the United States Public Health Service and had become profoundly impressed with their earnestness and vision, and their disinterested desire to care for the health of the people of the United States. He had been particularly impressed with the work and ability of Dr. Victor Heiser, now known to many as the author of *An American Doctor's Odyssey*.

Mr. McSweeney entertained Governor Walsh at his summer camp one week-end, and called his attention to the fact that Dr. Walcott's term would expire and that the Governor would be called upon to make a new appointment. He talked about public health throughout the whole week-end, and Governor Walsh was well prepared when Dr. Walcott told him that because of his age he could not accept a reappointment and told him about public health duties. He also understood, when Dr. Enos H. Bigelow, a representative at the State House, offered his assistance in any attempt at reorganization of the Board of Health, for which a number of petitions had been presented to the legislature. And in a message to the legislature the Governor recommended that there should be a reorganization of the Board of Health.

The year previous, the State of New York had reorganized its Department of Public Health, a bill with very elaborate details having been passed by the New York legislature. On a trip to New York, the writer interviewed both Dr. Herman Biggs, who had been made commissioner, and Homer Folks, who had been largely instrumental in securing the passage of the bill. They both were satisfied with the bill as it had been enacted, and had no important amendments to offer. With this report and a copy of the bill, the committee of the Massachusetts Medical Society had the basis for drawing a bill adapted to the needs of Massachusetts.

An official group of physicians specially interested in public-health matters held a meeting, which Dr. Walcott was invited to attend and state his ideas as to a reorganization of his board. He accepted the invitation but presented no really constructive ideas. While the good work that he had accomplished in the long years as chairman of the board was deeply appreciated, those at the meeting were disappointed to receive no forward looking message of guidance. However, a committee was appointed to try and draw up a bill to present to the legislature.

This committee met, considered the New York bill with its commissioner, district health officers, Department of Communicable Diseases, and so forth, and instructed one of its members to put the various suggestions into proper form. When this was done, and the bill had the approval of Governor Walsh,—it contained several of his personal suggestions,—it was introduced into the legislature by Dr. Bigelow.

Meantime, Mr. McSweeney made the suggestion that the Governor should get the promise of Dr. Heiser, then in the Philippines, that he would accept the position of commissioner should the bill become a law. Receiving a favorable answer, Governor Walsh went to a meeting of the Council of the Massachusetts Medical Society, gave his approval of the bill, and solemnly promised that he, on

1897 After a year as intern in Backus Hospital, Norwich, he began his practice in Shelton. He was a member of various Masonic groups, including Knights Templar and Mystic Shrine, and was also affiliated with the Connecticut State Medical Society and the New Haven and Fairfield County medical societies

STILLMAN—CHARLES K. STILLMAN, M.D., prominent in civic affairs, died in Mystic on March 22. Born July 15, 1879, in Plainfield, New Jersey, he was the son of the late Dr. Charles F. Stillman and Harriet Greenman Stillman, who survives him. His grandparents were prominent shipbuilders. Because of a difference between his parents when he was a boy, his father put him in the Cheltenham Military School in Pennsylvania, from which he was graduated in 1896. Returning then to his mother's custody, he went to Brown, was graduated in 1900 and went to Columbia Medical School, graduating in 1904. He interned at Bellevue Hospital and practiced in New York City several years. About twenty years ago he returned to Mystic where he practiced until ill health caused his retirement. Dr. Stillman was a lieutenant during the World War, stationed at Camp Wheeler in Georgia. He was a member of the Mystic Hook and Ladder Company, the Southern New England Fishermen's Association, and an organizer and officer of the Mystic Marine Historical Society.

HOLMES—LE VERNE HOLMES, M.D., chief orthopedic surgeon at Manchester Memorial Hospital, died suddenly of coronary thrombosis at the home of his daughter, Mrs. John Sinkinson, of Scarsdale, New York, he was in his fifty-ninth year. Dr. Holmes had been attending a conference and clinic of the College of Surgeons in New York City and was scheduled to return home the next day. Dr. Holmes was made medical examiner in April, 1935, and prior to that was assistant medical examiner for fifteen years. A native of Richmondville, New York, Dr. Holmes saw service in the Spanish American and the World wars. In the latter conflict, he was a lieutenant in the medical corps, specializing in orthopedic surgery. At the time of his death, he held a rank of lieutenant colonel, Medical Reserve Corps, 76th Division. He joined the hospital staff in Manchester on its opening in 1920 and on January 1, 1923, was placed in charge of the orthopedic service. Prior to that he served as school physician. Following graduation from Boston University School of Medicine in 1904, he served an internship at the Massachusetts Homeopathic Hospital, Boston, and began private practice in Arlington, Massachusetts. He went to Manchester in 1910 and, with the exception of his service in the World War, had practiced there since that time. He was vice president of the attending staff of physicians at the hospital and was secretary treasurer of the Manchester Medical Association. Prominent in civic affairs, he was vice president of the Y. M. C. A., president of the Manchester Country Club and a member of the Chamber of Commerce. He was a member of the Manchester Lodge of Masons, the Odd Fellows, and the Dilworth-Cornell Post, A. L. He was also a member of the Hartford County and Connecticut State medical societies and the American Medical Association. Besides his daughter, he is survived by his widow, Mrs. Ruth C. (Wiswall) Holmes, his father, Reuben Holmes, of Blenheim, New York, and a brother, Lindsay Holmes, of Cedar Falls, Iowa.

RING—HENRY W. RING, M.D., prominent retired eye and ear specialist and a former ophthalmologist at Yale University, died on April 3 at New Haven at the age of eighty-one. He was a native of Portland, Maine, and was

graduated from Bowdoin College in the class of 1879 and from Bowdoin Medical School in 1887. After starting practice in New Haven in 1889, Dr. Ring became acting and consulting ophthalmologist at the New Haven Hospital and secretary of the Board of Directors. He retired in 1925 and for the next ten years was ophthalmologist in the Department of Health at Yale. He was responsible for passage of a law in Connecticut for prevention of blindness of the new born. Dr. Ring was a former president of the New York Ophthalmological Society.

KELLY—JAMES F. KELLY, M.D., physician and pathologist, died at St. Francis Hospital, April 3, of injuries received in a fall at his home less than an hour earlier, he was thirty-one years old. He had opened his practice only a little more than a year ago. A native of Hartford, Dr. Kelly was graduated from Trinity College in 1929 and from Yale Medical School in 1933. He served his internship at the Meriden Hospital and at St. Francis Hospital. Following special training in pathology in Toronto, Canada, he began practicing in Hartford in January, 1937. Dr. Kelly was a member of the Hartford Medical Society, the Hartford County Medical Association and the Connecticut State Medical Society. He was not married. He was the son of Mrs. Mary Callahan Kelly, of Hartford, and the late James J. Kelly. Besides his mother, he is survived by a sister, Miss Ruth M. Kelly, of Hartford.

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR APRIL, 1938

DISEASES	APRIL 1938	APRIL 1937	FIVE YEAR AVERAGE*
Anterior poliomyelitis	0	0	1
Chickenpox	1301	1493	1136
Diphtheria	16	11	39
Dog bite	964	990	845
German measles	104	157	1932
Gonorrhea	399	453	453
Lobar pneumonia	542	646	521
Measles	1437	2983	4364
Meningococcus meningitis	7	30	16
Mumps	1107	785	956
Paratyphoid B	6	34	7
Scarlet fever	1640	1172	1212
Syphilis	516	560	460
Tuberculosis pulmonary	447	339	299
Tuberculosis other forms	48	30	33
Typhoid fever	3	4	8
Undulant fever	2	3	3
Whooping cough	421	1421	956

*Based on figures for preceding five years

RARE DISEASES

Diphtheria was reported from Danvers, 1, Fall River, 1, Lexington, 6, Melrose, 1, Salem, 1, Somerville, 1, Westwood, 1, Worcester, 4, total, 16.

Meningococcus meningitis was reported from Beverly, 1, Boston, 3, Franklin, 1, Holyoke, 1, New Bedford, 1, total, 7.

Paratyphoid B was reported from Fall River, 2, Lynn, 3, Reading, 1, total, 6.

Pfeiffer bacillus meningitis was reported from Spencer, 1.

Septic sore throat was reported from Arlington, 1, Boston, 4, Cambridge, 2, Greenfield, 1, Lawrence, 2, Lexington, 1, Lowell, 1, Lynn, 13, Randolph, 1, Salem, 1, Waltham, 1, total, 28.

Trichinosis was reported from Boston, 4.

Typhoid fever was reported from Brookline, 1, Revere, 1, Watertown, 1, total, 3.

Undulant fever was reported from Clarksburg, 1, Sturbridge Center, 1, total, 2.

The incidence of chickenpox dropped from a record high of three months duration to a more normal figure.

HEALTH CONSERVATION CONTEST

To the Editor The trophy awarded to the Boston Chamber of Commerce, in recognition of Boston's achievement in winning the 1937 Inter-City Health Conservation Contest for cities of 500,000 or over, now adorns the office of the Boston Health Commissioner

All agencies and individuals who contributed to the winning of the award, as well as all others interested, are cordially invited to come to the office of the Health Commissioner in order to see this trophy, which is a bronze tablet or plaque.

The Boston Health Department takes this occasion again to express its thanks to all who, by their co-opera-

tion and by their contribution of data upon preventive-medicine measures, aided in the winning of this award.

GOVERNMENTAL CONTROL OF THERAPEUTIC PREPARATIONS

To the Editor The American Society for Pharmacology and Experimental Therapeutics unanimously adopted the following resolution at its twenty-ninth annual meeting held in Baltimore, Maryland, April 2

The American Society for Pharmacology and Experimental Therapeutics, Inc., views with alarm the lack of statutory regulation of the sale or use of dangerous therapeutic preparations, which result in such tragedies as the recent series of deaths from Elixir of Sulphanilamide and from contaminated serum. Furthermore, the present and increasing promiscuous use by the public and especially the youth of this country of drugs having either a pronounced stimulating effect or a profound depressing effect on the nervous system is an alarming situation calling for immediate remedial measures in the interest of public health and safety. Therefore, the American Society for Pharmacology and Experimental Therapeutics, Inc., in annual meeting assembled, respectfully but firmly urges that the governmental authorities, through Congress, be given the necessary power to regulate the sale to or the use by the general public of such preparations as are dangerous or inimical to public health and safety. Be it further resolved that new or untried drugs should not be allowed to come into use by the general public before authoritative sanction has been obtained. Be it further resolved that copies of this resolution be sent to all appropriate governmental and medical organizations

REPORT OF MEETING

BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

A meeting of the Boston Society of Psychiatry and Neurology was held at the Boston Medical Library on April 21. Dr Tracy J. Putnam presided. Following a brief business meeting, four papers were presented.

The first paper was given by Dr Putnam and dealt with "The Relief of Unilateral Paralysis Agitans by Section of the Pyramidal Tract." Two patients were shown, with moving picture demonstrations of their symptoms prior to operation. The first patient was a fifty-seven-year-old man with incapacitating paralysis agitans affecting the left side. Following section of the left pyramidal tract, his tremor subsided almost completely, and he was able to perform many co-ordinated movements which had previously been impossible. The second patient was a thirty-two-year-old woman, who had been almost totally incapacitated by paralysis agitans on her right side. She showed almost complete relief of tremor following section of the right pyramidal tract. Both these patients showed no impairment of voluntary motor power and co-ordination postoperatively. In the first patient the abnormal reflexes (Hoffmann, Babinski, Gordon, Rossolimo, and so forth) of pyramidal tract damage appeared

the enactment of the legislation, would give to the State of Massachusetts a commissioner of the highest standing.

As soon as the bill was introduced, quiet but vigorous opposition developed, the *Boston Evening Transcript* taking the lead. Although the Governor and many physicians and laymen appeared in its support, when it emerged from the committee, it was hardly a skeleton of the original bill.

Dr Biggs, the New York commissioner, chanced to be in town, read the bill and pronounced it a workable, though not ideal, piece of legislation.

With that endorsement from such an astute politician, the committee was encouraged to continue its efforts to have the bill enacted. But at one of the last hearings before the Senate Ways and Means Committee, the representatives of the doctors were astonished to have an assistant from the Board of Health appear and say that he had been instructed by the author of the original draft of the bill to appear before the committee and state that he considered the bill then before the Senate unworkable and therefore, that he withdrew his approval of the proposed legislation.

In spite of this unexpected blow, Governor Walsh was able to win over the chairman of the Ways and Means Committee to support the bill and it was passed at the final session of the legislature early in July, 1914.

The legislature adjourned, and the bill was a law, a new commissioner was to be appointed, but Dr Heiser could not be found. Even his best friends could not locate him. A commissioner *pro tem* was appointed, and finally the missing Dr Heiser reported to the Governor that, as he had heard nothing from Massachusetts for over six months, he had concluded that the legislation had not been enacted and that he had yielded to the offer of the Rockefeller Foundation to become its health agent—an office which he has so efficiently filled. He suggested to the Governor the names of three men in the United States Public Health Service, who, he was sure, would be able to organize the new department.

Soon after this, the Governor was thrown from his horse and was laid up with a broken arm. Only a few knew of the fact that Dr Heiser was unable to take the post. This knowledge was kept secret, as the Governor was most anxious to redeem his pledge that the new commissioner should be a man of undoubted ability and with public-health training.

Finally, he asked Mr McSweeney and the writer to go to Washington to see President Wilson and ask that Massachusetts should be given, for a term of years, an able man from the United States Public Health Service to assume the duty of organizing the new Department of Public Health. Mr McSweeney was to represent that here was a Democratic governor in a then Republican state who had promised that he would give to the doctors and the people of the State an efficient, well trained health commissioner, and that the loss of their support would be fatal in an uphill fight for re-election.

Although Mr McSweeney did not see the President, he did interview Surgeon General Blue. The three names were given to him, and he was asked for one of them. The Surgeon General threw up his hands in horror and said,

"You gentlemen have named the three best men in the service. I cannot let one of them go." He offered a substitute, who, on investigation, was found to be undesirable for this position.

The following day, Surgeon General Blue finally agreed that Dr Alan J McLaughlin, one of the men asked for, might be released when a piece of work on which he was engaged was finished. Then, for one reason or another,

the negotiations dragged until Governor Walsh, taking an active hand in the matter, communicated directly with Dr McLaughlin, and the appointment was made.

Thus, Governor Walsh redeemed his pledge that he would appoint, as the commissioner of public health, a man highly trained in public health matters.

INSURANCE COMPANIES THAT HAVE ACCEPTED THE GENTLEMEN'S AGREEMENT

To the Editor I have been asked a number of times for the names of the insurance companies which have accepted the Gentlemen's Agreement. I am enclosing such a list and believe it would be advisable to have it published in the *Journal* so that each member of the Society could know the companies that are included.

H. M. LANDESMAN, M.D.

366 Commonwealth Avenue,
Boston, Mass

* * *

The list of insurance companies doing business in Massachusetts under the Gentlemen's Agreement is as follows:

Accident and Casualty Insurance Company of Winterthur, Switzerland, of New York, New York, N Y

Aetna Casualty and Surety Company, Hartford, Conn.

Aetna Life Insurance Company, Hartford, Conn.

American Automobile Insurance Company, St. Louis, Mo

American Bonding Company of Baltimore, Baltimore, Md.

American Casualty Company, Reading, Pa.

American Employers' Insurance Company, Boston, Mass.

American Surety Company of New York, New York, N Y

American Re-Insurance Company, New York, N Y

Associated Indemnity Corporation, San Francisco, Calif

Bankers Indemnity Insurance Company, Newark, N J

Car and General Insurance Corporation, Limited, New York, N Y

Central Surety and Insurance Corporation, Kansas City, Mo

Century Indemnity Company, Hartford, Conn.

Columbia Casualty Company, New York, N Y

Commercial Casualty Insurance Company, Newark, N J

Continental Casualty Company, Chicago, Ill.

Eagle Indemnity Company, New York, N Y

Employers' Liability Assurance Corporation, Limited, Boston, Mass

Employers' Reinsurance Corporation, Kansas City, Mo

European General Reinsurance Company, Limited, New York, N Y

Fidelity and Casualty Company of New York, New York, N Y

Fidelity and Deposit Company of Maryland, Baltimore, Md.

Fireman's Fund Indemnity Company, San Francisco, Calif

First Reinsurance Company of Hartford, Hartford, Conn

General Accident, Fire and Life Assurance Corporation, Limited, Philadelphia, Pa.

General Reinsurance Corporation, New York, N Y

Glens Falls Indemnity Company, Glens Falls, N Y

Globe Indemnity Company, New York, N Y

Great American Indemnity Company, New York, N Y

Hartford Accident and Indemnity Company, Hartford, Conn

Hartford Steam Boiler Inspection and Insurance Company, Hartford, Conn

Home Indemnity Company, New York, N Y
 Indemnity Insurance Company of North America, Philadelphia, Pa.
 London and Lancashire Indemnity Company, Hartford, Conn
 London Guarantee and Accident Company, Limited, New York, N Y
 Maryland Casualty Company, Baltimore, Md
 Massachusetts Bonding and Insurance Company, Boston, Mass.
 Metropolitan Casualty Insurance Company of New York, Newark, N J
 National Casualty Company, Detroit, Mich
 National Surety Corporation, New York, N Y
 New Amsterdam Casualty Company, Baltimore, Md
 New York Casualty Company, New York, N Y
 Norwich Union Indemnity Company, New York, N Y
 Ocean Accident and Guarantee Corporation, Limited, New York, N Y
 Oregon Automobile Insurance Company of Portland, Portland, Oregon
 Pacific Indemnity Company, Los Angeles, Calif
 Phoenix Indemnity Company, New York, N Y
 Preferred Accident Insurance Company, New York, N Y
 Royal Indemnity Company, New York, N Y
 Seaboard Surety Company, New York, N Y
 Standard Accident Insurance Company, Detroit, Mich
 Standard Surety and Casualty Company of New York, New York, N Y
 Sun Indemnity Company, New York, N Y
 Travelers Insurance Company, Hartford, Conn
 Travelers Indemnity Company, Hartford, Conn
 United States Casualty Company, New York, N Y
 United States Fidelity and Guaranty Company, Baltimore, Md.
 United States Guarantee Company, New York, N Y
 Yorkshire Indemnity Company, New York, N Y
 Zurich General Accident and Liability Insurance Company, Limited, Chicago, Ill.
 American Mutual Liability Insurance Company, Boston, Mass.
 Liberty Mutual Insurance Company, Boston, Mass
 Lumbermens Mutual Casualty Company, Boston, Mass
 Merchants Mutual Casualty Company, Boston, Mass

RESTORATION OF LICENSE

To the Editor This is to inform you that at the meeting of the Board of Registration in Medicine held April 28, it was voted to restore the certificate of registration of Dr Russell B Street, of Conway

STEPHEN RUSHMORE, M.D., *Secretary*

Board of Registration in Medicine,
 State House, Boston

HEALTH CONSERVATION CONTEST

To the Editor The trophy awarded to the Boston Chamber of Commerce, in recognition of Boston's achievement in winning the 1937 Inter-City Health Conservation Contest for cities of 500,000 or over, now adorns the office of the Boston Health Commissioner

All agencies and individuals who contributed to the winning of the award, as well as all others interested, are cordially invited to come to the office of the Health Commissioner in order to see this trophy, which is a bronze tablet or plaque.

The Boston Health Department takes this occasion again to express its thanks to all who, by their co-opera-

tion and by their contribution of data upon preventive-medicine measures, aided in the winning of this award.

H F R. WATTS, M.D., *Health Commissioner*
 City Hall Annex,
 Boston.

GOVERNMENTAL CONTROL OF THERAPEUTIC PREPARATIONS

To the Editor The American Society for Pharmacology and Experimental Therapeutics unanimously adopted the following resolution at its twenty ninth annual meeting held in Baltimore, Maryland, April 2

The American Society for Pharmacology and Experimental Therapeutics, Inc., views with alarm the lack of statutory regulation of the sale or use of dangerous therapeutic preparations, which result in such tragedies as the recent series of deaths from Elixir of Sulphanilamide and from contaminated serum. Furthermore, the present and increasing promiscuous use by the public and especially the youth of this country of drugs having either a pronounced stimulating effect or a profound depressing effect on the nervous system is an alarming situation calling for immediate remedial measures in the interest of public health and safety. Therefore, the American Society for Pharmacology and Experimental Therapeutics, Inc., in annual meeting assembled, respectfully but firmly urges that the governmental authorities, through Congress, be given the necessary power to regulate the sale to or the use by the general public of such preparations as are dangerous or inimical to public health and safety. Be it further resolved that new or untried drugs should not be allowed to come into use by the general public before authoritative sanction has been obtained. Be it further resolved that copies of this resolution be sent to all appropriate governmental and medical organizations

 Boston

REPORT OF MEETING

BOSTON SOCIETY OF PSYCHIATRY AND NEUROLOGY

A meeting of the Boston Society of Psychiatry and Neurology was held at the Boston Medical Library on April 21. Dr Tracy J Putnam presided. Following a brief business meeting, four papers were presented.

The first paper was given by Dr Putnam and dealt with 'The Relief of Unilateral Paralysis Agitans by Section of the Pyramidal Tract'. Two patients were shown, with moving-picture demonstrations of their symptoms prior to operation. The first patient was a fifty-seven year-old man with incapacitating paralysis agitans affecting the left side. Following section of the left pyramidal tract, his tremor subsided almost completely, and he was able to perform many co-ordinated movements which had previously been impossible. The second patient was a thirty-two-year-old woman, who had been almost totally incapacitated by paralysis agitans on her right side. She showed almost complete relief of tremor following section of the right pyramidal tract. Both these patients showed no impairment of voluntary motor power and co-ordination postoperatively. In the first patient the abnormal reflexes (Hoffmann, Babinski, Gordon, Rossolimo, and so forth) of pyramidal tract damage appeared

postoperatively. In the second patient there had been some signs of pyramidal-tract disease present before operation, and no increase in these could be determined postoperatively. Other types of operation for paralysis agitans have been reported in the literature as unsuccessful, including anterior-quadrant section of the extrapyramidal fibers and also section of the posterior columns.

The second paper of the evening was presented by Dr. Paul F. A. Hoefler and Dr. Putnam on "Electromyographic Studies in Spastic Conditions and in Paralysis Agitans." Dr. Hoefler demonstrated a series of electromyographic tracings from the muscles of patients. Potentials were determined by superficial leads on the skin and by penetrating muscle electrodes. It was found that the ankle clonus of spastic extremities was composed of rhythmic bursts of action impulses with quiescent intervals. Each burst had a definite pattern of amplitude. Single ankle jerks in normals were found to consist of single diphasic discharges. It was possible to get contralateral reflex discharges in spastics, and also homolateral reflexes from other muscles of the same side. Single ankle jerks in spastics were followed by an afterdischarge.

Electromyographic recordings in paralysis agitans showed a rhythmic, regular series of discharges with quiescent intervals, bearing a close resemblance to the tracings in spastic clonus. In patients with unilateral tremors, it was possible to record faint rhythmic discharges from muscles on the unaffected side. In several cases of generalized tremor, leads were taken from numerous muscle groups including the masseter and calf muscles. In these cases, it was found that the rhythm of discharge was the same in all muscles, with variations only in intensity. This synchronicity of action impulses suggests a central discharging mechanism situated high in the neuraxis, the possibility is also brought up that the fibers carrying impulses to various muscles may have graded variations in their size, degree of myelination and conduction time.

Patients with postencephalitic Parkinsonism without tremor showed irregular rhythmic discharges, suggesting the underlying mechanism of cogwheel rigidity.

The effect of curare on clonic tremors in several patients was studied electromyographically. A great reduction in the amplitude of rhythmic discharges was seen, which corresponded with the clinical improvement seen for twenty-four hours after curare administration.

The similarity between clonus and tremor has been commented on by numerous workers and is further substantiated by the electromyographic records. The central basis for the two mechanisms might be suggested to be the same. Further evidence for this is supplied by the results of pyramidal tract section in paralysis agitans.

The third paper was presented by Dr. Wilfred Bloomberg, whose subject was "The Results in the Treatment of Chronic Alcoholism by Benzadrine." A preliminary report. Dr. Bloomberg discussed 10 cases of chronic alcoholism that have been under benzadrine treatment during the past year. Most of the cases were patients who had tried numerous other forms of therapy without success. The majority appeared to be definitely benefited by benzadrine, with the alcohol intake completely eliminated in some. It was suggested that the drug acted to relieve depression and to supply a "lift," during which alcohol was no longer necessary. It provides a promising means of producing a latent interval of sobriety for several months, during which time psychotherapy may be introduced with better effect.

Dr. Bloomberg also presented several slides showing the studies which have been made on a series of narcolepsy

patients, who have been under intensive benzadrine treatment for the past two years. These included blood counts, metabolic determinations, blood pressure readings, and cardiac, renal and hepatic studies. No abnormalities resulting from the drug could be found in any of the patients, some of whom had been receiving 120 mg. a day for two years. No symptoms of addiction were observed.

The final paper was presented by Dr. Joseph J. Michaels and Miss Sylvia E. Goodman, it was entitled "The Incidence and Age of Cessation of Enuresis in One Thousand and Neuropsychiatric Patients." Dr. Michaels demonstrated a series of statistical studies made on 1000 patients at Ann Arbor, with 1000 representative normals as a control group. The highest incidence of enuresis, together with the longest persistence of enuresis, was found in the group of patients with psychiatric behavior problems and psychopathic personalities. The lowest incidence was encountered in the group of frank psychotics. The percent age of incidence in normals lay between these two groups.

Enuresis is a significant index of disharmony within the personality, indicating a lack of maturation. The frequent history of early enuresis with later delinquency suggests a disturbance in the fundamental psychobiologic mechanism.

NOTICES

CANADIAN MEDICAL ASSOCIATION

The Canadian Medical Association is holding its sixty-ninth annual meeting in Halifax, Nova Scotia, on June 20, 21, 22, 23 and 24. A highly interesting program consisting of approximately one hundred papers, clinics and demonstrations will be presented. To all fellows of the American Medical Association we extend a cordial invitation to attend. Registration as a guest will be effected upon presentation of a card of fellowship in the American Medical Association.

Inasmuch as the American Medical Association is holding its annual session this year in San Francisco, we should particularly like to remind the fellows residing in the New England states and on the Atlantic seaboard, that, if they find it inconvenient to attend their own meeting, a very hearty welcome awaits them in Halifax.

T. C. ROUTLEY, M.D., *General Secretary*,
Canadian Medical Association.

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

There will be a special meeting of the New England Society of Physical Medicine in the Men's Lounge, Hotel Bradford, Thursday, June 2, following the program of the Section of Radiology and Physiotherapy of the Massachusetts Medical Society.

Members are urged to attend the excellent program of the section in the Oval Room at 9:30 a. m.

WILLIAM D. McFEE, M.D., *Secretary*

RADIO BROADCASTS

The ninth group of weekly broadcasts sponsored by the American Medical Association and the National Broadcasting Company concern health knowledge. These dramatized health messages are intended to furnish supplementary material for health teaching in junior and senior high schools and are broadcast every Wednesday

from 2 00 to 2 30 p. m. over the Red Network. The dates and subjects are as follows

June 1—Vacation Plays and Mis-plays Making the vacation a real contribution to health and recreation.

June 8—Graduation and Then What? A new phase of life begins at commencement, and health contributes to success

June 15—What Medicine Offers for Health Flashes from the American Medical Association meeting at San Francisco, giving high lights of medical progress

CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS, UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	ORTHOPEDIC CONSULTANT
Haverhill	June 1	Arthur T. Legg
Lowell	June 3	Albert H. Brewster
Salem	June 6	Harold C. Bean

Hyannis	June 28	Paul L. Norton

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The oral, clinical and pathological examinations for Group A and Group B applicants will be held in San Francisco, California, on Monday and Tuesday, June 13 and 14

An informal dinner for the diplomates of the board, their wives and others interested in the work of the board, will be held at the Palace Hotel, San Francisco, on Wednesday evening, June 15, at 7 00. Dr. William D. Cutter, secretary of the Council on Medical Education and Hospitals of the American Medical Association, will address the group

Application blanks and booklets of information may be obtained from Dr. Paul Titus, *Secretary*, 1015 Highland Building, Pittsburgh, Pennsylvania

BOOK REVIEWS

The Patient and the Weather William F Petersen, with the assistance of Margaret E. Milliken Volume 4, Part 3 651 pp Ann Arbor Edwards Brothers, Inc., 1938 \$10 00

This third part of Volume 4 of the monographs on *The Patient and the Weather* deals with surgical problems of organic disease Petersen in the preface states 'Superficially it links the patient who may be suffering from an acute abdominal condition to meteorological environment.

But the mere precipitation of the acute clinical event by meteorological change is not of ultimate significance for the broader problem If the acute episode is so conditioned, the pathogenesis may in some fashion be associated with the meteorological environment as one of a series of factors in the constellation Many modern surgeons may be chagrined to learn that this is no new approach to their field of work but dates back to a dictum of Hippocrates One should be especially on one's guard against the most violent changes of the seasons, and unless compelled, one should neither purge nor apply cautery or knife to the bowels, until at least ten days have passed'

In the previous monographs in this series the scientific explanation of the effect of meteorologic change has been discussed In part this effect is one of vasomotor and neuromuscular dysfunction For the tissue phase of increasing blood pressure, that is, the relative closure of portions of the vascular bed, Petersen uses the designation ARS, for during this status there is a relative anoxemia, anabolism, reduction and spasm, with higher pH and enhanced adrenal effectiveness His COD phase is one of decreasing blood pressure—a period of catabolism, oxidation and dilatation of vessels, with 'thyroid'

preponderance. A pressor increase (ARS) may be due to a meteorologic alteration (polar infall, unusual heat or humidity), emotional or physical trauma, exertion or infection, therefore ARS is a sympathicotonic phase.

The author suggests several observations which have a bearing on general surgical problems the role of smooth muscle spasm (vascular as well as visceral), and its associated anoxia of related mucous membranes, for necrosis and bacterial penetration, the rhythm of organic stimulation and of overstimulation and fatigue as it concerns resistance, and the relation of this to season, to the individual meteorologic episode, to the menstrual cycle, and so forth

This large quarto book contains 482 graphs and tables and numerous case histories In the introductory chapter Petersen discusses the effect of environment on the 'humors,' infection and inflammation. The major themes of the succeeding thirteen chapters are ulcer of the stomach and duodenum, Meckel's diverticulum, the gall bladder, acute pancreatitis, appendicitis, disturbances of the bowels, ectopic pregnancy, postoperative complications, vascular accidents, brain abscess, meningitis, orthopedic cases, ophthalmological episodes, and the endemology of surgical diseases References to the literature are given in copious footnotes

Before specifically presenting, by case histories and charts, the coincidence of clinical episodes and weather changes in the several diseases under consideration, the author discusses the recent concepts of their pathogenesis. These discussions should be of great interest to surgeons, particularly those concerning peptic ulcer and appendicitis The larger charts, which combine meteorologic and clinical data, are soon comprehended. Unusual episodes in the course of cases are designated by numerals in circles These episodes are similarly marked in the case histories The effect of seasonal and sun spot cycles is discussed Every surgeon need not be a meteorologist or astronomer, but every thoughtful surgeon will profit by examining this work by Petersen.

In an effort to make the publication of scholarly and technical books in small editions pay for themselves, publishers are making use of the photolithograph process from perfect type script, the pages are large, but the type clear and easily readable.

Man Against Himself Karl A. Menninger 485 pp New York Harcourt, Brace and Company, 1938 \$3 75

This book unfortunately is not scientific. It seemingly is written for lay readers, but even lay readers will hesitate to accept such a statement as, 'In the unconscious we are still animals and there is no reason to believe that any animal fears death'

The book is interesting for what the writer discloses rather than what he headlines. The statement, 'The fourth section deals with an extension of the theory of self destruction to the problem of physical disease, an extension which must be considered, as yet, largely hypothetical,' discloses an unexpected hesitance on the part of the author—a Freudian disciple—to maintain the undisputable authenticity of his theories Also, the remark of the author, 'I have a large file full of such clippings, when referring to the suicides of former patients, discloses what many have feared that as a type of therapy the Freudian, or perhaps better the pseudo-Freudian, doctrines may often upset unbalanced minds and result in suicide.

So far as assistance in handling the suicide problem is concerned this book adds little—in fact the author's suggestions seem far from novel, original or well expressed to anyone familiar with Christ's teachings.

THE PASSING OF SURGICAL YEOMEN

ALLEN G. RICE, M.D.*

SPRINGFIELD MASSACHUSETTS

AN ORATION postulates an orator. When therefore, an oration is ventured by one neither oratorically endowed nor trained, only natural is query as to the propriety of the caption. Custom, however, oftentimes violates the true meaning of words until their new connotations come to be tolerated without undue qualms. That this society is by no means innocent of abetting such neologic misdemeanor is apparent on scanning the list of past occupants of this rostrum. There seem to have been very few orators. Be that as it may, they triumphed, one and all, with the brilliance and worth of their offerings. The honor of being chosen to this company of the specially ordained is signal. The task of nearing the standard they set is awesome. Yet earnestly withal has this year's conscript striven to be worthy of his hire. He stands here in all humbleness as his becomes the latest name added to that famed roster whose luster he can only hope will not thereby be unduly dimmed.

Yeomen are gallant men who render great and loyal service. The title was first bestowed on those chosen for their valor and lealty to be trusted bodyguards for kings and nobles. Somewhat later whole companies of tried loyalty were so dubbed, and later still regiments that to this day are proud of their traditional crest. In all the world's wars yeomen were the backbone of armies and the mainstay of navies. As conflicts waned and peacetimes came oftener and lasted longer, and as unwarlike pursuits were more generally followed, the honored title of yeoman was given men who otherwise than as soldiers rendered equally great and loyal service. So through the years the order of yeomanry gained in stature, luster and good repute. In husbandry and trade, in the crafts and arts, in the missions of priesthood and teaching, in all lines of human endeavor, the staid and sturdy men were the yeomen. Lords over none, under human bondage to no man, they were freeborn

commoners. Without any ado they went earnestly and noiselessly about their business. Never did they vision quick reward, but rather the lasting joy and contentment from good works well done. For them sufficient unto the day was the labor thereof. Their virtues were their reward. For their reserve and unobtrusiveness they went unnoted and unsung the while they did the bulk of the world's work. They were the builders of wealth, the winners of knowledge, the guardians of morality. As once they were the might and power of wartime forces, so later in peace were they the strength and the weal of social, economic and civic orders, the bulwark of the state, the leaven of civilization, the wellspring of culture.

Hence were they resolute,
Leading the van on every day of battle,
As men who knew the blessings they defended.
They were worth their breeding, which doubt not,
For there was none of them so mean and base
That had not noble luster in his eyes.

Such were yeomen. Their order still lives with all its noble traditions, but its solid ranks of old are thinned. Sturdiest of the league, truest to its unwritten precepts, surest hope for its salvation, are surgical yeomen. They are the grandsons of stanch and peerless forebears, the rank-and-file physicians of yesteryear. These grandsires were the common doctors, they of the commonalty, but of the first and most respected class. For the most part they were countrymen or everyday citizens, physicians of the district. Impelled not by force from without, but from within by the drive of their own strong natures, they were masters of their own destinies, and in all times the strength, the spirit and the glory of the profession. Workers, not idlers, followers but not stragglers, thinkers, not dreamers, servants but not slaves, they bred in themselves the self-respect, the self-reliance, the self-discipline and the self-culture that were priceless gifts to the commonweal of medicine. Neither great renown nor great riches was often

*The Annual Discourse delivered at the annual meeting of the Massachusetts Medical Society, Boston, June 2, 1938.
Visiting surgeon, Springfield Hospital, Springfield, Massachusetts.

theirs True to their self-chosen order of yeomanry, they were the hewers of wood and the carriers of water Through the years their good works went unsung until in the fullness of his heart Robert Louis Stevenson wrote

There are men and classes of men that stand above the common herd, the soldier, the sailor, and the shepherd not infrequently, the artist rarely, rarer still the clergyman, the physician almost as a rule. He is the flower (such as it is) of our civilization, and when that stage of man is done with, and only remembered to be marveled at in the defects of the period, and most notably exhibited in the virtues of the race. Generosity he has, such as is possible to those who practice an art, never to those who drive a trade, discretion, tested by a hundred secrets, tact, tried in a thousand embarrassments, and what are more important, Heracleian cheerfulness and courage. So it is that he brings air and cheer into the sickroom, and often enough, thought not so often as he wishes, brings healing

About the time this tribute to the family doctor was penned, a new order was forming within the ranks of medical men It was joined by those general practitioners with leanings and flairs for surgery Into the new fields opened up by Lister's gift they drove They were the pioneers of modern surgery With boundless faith in their art and with courage undaunted by difficulties and early failures, they pressed on with a daring that bespoke their skill and a caution that vouched their wisdom They need this late day no inspired bard or rare scribe to do them homage Theirs are names that live

It was from these pioneers that sprang a race of surgeons Some of this second generation, those richest endowed with quick heads, daring hearts and deft hands, have become renowned masters of their art They, like their fathers before them, need this day no recalling Rather is it their lowly brethren, that host of general surgeons, long lost from mind and eye in the far-flung surgical world, who, overlooked and unrated, merit, nonetheless, appraisal which has never been vouchsafed They are the surgical yeomen

In this day and hour they are the old guard, in large measure self-made surgeons Their medical-school course and their training as surgical interns were, judged by present lights, meager indeed and of little worth Surgical teaching was encumbered with tradition Operative fields were not many Years of trial and error had not yielded refined and standardized technic The tools of the craft were far from perfected Care before as well as after operation was little understood, therefore crude and sometimes harsh But the old guard never faltered Their own guides on often strange and sometimes uncharted ground, they found their own way Despite their stunted schooling

and training, steadied by common sense, backed by resourcefulness, impelled by need, they overcame their handicaps, and day in and day out have given earnest of the sterling worth of head and hand

These surgical yeomen did, however, have a priceless course of training, nowadays rather disdained Most of them, for one reason and another, began as general practitioners of medicine, and followed that calling for several years As family doctors they took on stature and grew wise in the art of practice, which is the same, be it medical or surgical,—an art, too, which is better mastered at the family bedside than in the hospital ward Not that they neglected surgery Quite the contrary they saw to it that they were known as physicians who did surgery When the time came for them to break away from general practice, enough surgery was forthcoming from their lay followings to tide them over the transitional years before medical brethren entrusted to them patients for operation Whatever sins of omission this apprenticeship of yesteryear may have had, it had few, if any, of commission, and it did have virtues which, if they awarded little of scientific merit, did have something to do, indirectly at least, with the making of dependable and beloved surgeons

Started on their careers with handicaps of under-schooling and inexperience, they found their chosen course roughened by hazards that only their fortitude and resourcefulness overcame They had neither drilled assistants nor skilled anesthetists For many reasons, most of them needful, some becoming, but a few, alas, sordid, all too often they had to tolerate across the table a doctor unused to surgical technic, and at the head another untutored in giving ether Of the two the former was more easily borne His clumsy and risky doings could be watched and guarded against while the operator did all the work himself The anesthetist, however, was a tougher problem Etherizing quite commonly looked down upon as a drab and menial chore with none of the glamorous appeal of the operating room, was usually a leftover job for whosoever at the moment was not otherwise busy It was, then, not at all strange that these casual anesthetists, unfitted for the task and with untoward interest in the open abdomen, too many times harried overburdened surgeons with blue-lipped, wet-throated, rigid, straining patients, or not rarely with pallid, faintly sighing forms whose toneless muscles heralded oncoming shock Furthermore, the tools of these surgical craftsmen were not always of the latest pattern, the fittings and structure of their workshops were like as not

outdated, but from long and close companionship they were endeared to their owners who learned well to use them handily. Indeed, it was no rare feat for them to operate in the home, on the kitchen table, with dry goods from their own Arnold sterilizers, and with instruments boiled on the family cookstove. These and other hardships, endured and transcended, have richly endowed this race of surgical yeomen with the unconquerable spirit, the unshakable poise and the steadiness of mind and hand that only trials unflinchingly faced and resolutely overcome can bequeath.

The first aim of the old guard has ever been to get sick people well. Eager for the learning and skill that would grant them that power, they left no stone unturned to acquire them. They had no urge to be scholars and laid no claim to that high estate, they were just diligent, lifelong students. They read chiefly the pick of weekly and monthly journals, for they knew that most new books were already outdated when published. To quicken their minds they went often to meetings of their peers, there to listen closely, to speak seldom, and better to guide their eager hands, oft as might be though rarelier than they wished, they stole away to surgical meccas where, watching masters, they picked up new leads to diagnosis, new tricks of technic, new wards against disaster and new handling of mishaps.

Of such sterling stock and self-willed discipline are surgical yeomen. There are still a goodly number of them in the land, how many, there is no telling. True to the order of yeomanry, they are the forgotten ones who staff the many hospitals in byways of cities and at rural crossroads. Day in and day out these willing craftsmen go quietly about their business here, there and everywhere, never exploited by the press. And so it is that, notwithstanding master surgeons and their hand-picked helpers in famed clinics, the bulk of the country's surgery is really done by a company of forgotten men.

Mere quantity, however, is no token of the scope and kind of surgery they do. While the former is perhaps not of the widest, its range is by no means narrow. Annual reports from thirty small-town hospitals east of the Mississippi list about the same run of operations as do large clinics, for appendicitis, rupture, gall-bladder disease, cancer of the breast, empyema, pelvic tumors, childbirth repairs and a multitude of traumatic ills. In many there is a quite sizable ratio of thyroidectomies, stomach and bowel resections, splenectomies and rectal excisions, to say naught of orthopedic, urological and some thoracic operating where, be it noted, no specialists are registered. This is no narrow reach of surgical endeavor. More's the wonder, it is

spanned not in part by one man here and another there, but in its entirety by most veoman surgeons. Each and every one of them stands in readiness to take out a gallbladder today, a thyroid tomorrow and a prostate the day after. Spontaneous and natural it is to marvel at the deftness and skill of a master who numbers his thyroidectomies in the thousands, but could he be otherwise with such vast experience? The real wonder is that yeomen who do perhaps one or two, or even less a week, can remove goiters with the dexterity they do.

In order to rate the quality of surgery done anywhere, resort must be had to figures. That is always a risky venture, for statistics can be made to prove almost anything. There are two yardsticks for measuring the worth and benefits of surgery: mortality and morbidity. Now, well-being after operation is not at all easy to record. Percentages of results good and results bad are apt to be gay deceivers, playing as they unwittingly do, patients' emotional self-appraisals against surgeons' optimistic desires. Happy outcomes can be stressed, feigned or hidden by human frailty on the one hand, and on the other, setbacks can be as easily sidetracked, pardoned or shaded by equally human professional zeal. From their very nature, then, morbidity statistics are too sensitive to warping to be nice measuring rods. The death rate, on the contrary, is, save for the chance upset of wrong diagnosis, quite positive and accurate, whatever else betides, patients either live or die. Whether or not low mortality is the chief aim of surgery, it is still on the whole the truest token of its worth, the surest common yardstick for all surgeons.

Averaged from hospital reports, the general surgical death rate at the hands of six master surgeons is 4.6 per cent, of thirty scattered yeomen 4.8 per cent, a creditable showing indeed for the lowly ones. This near parity of outcome is of course wide open to attack. That surgical lords who handle the more hazardous jobs do not have a worse mortality is for them a credit just and merited, but, alas, so intangible it cannot be figured. In all fairness, too, must it be admitted that yeomen, by shunting their more perilous work onto their betters, thereby escape a debit equally merited, but likewise too fitful for computation. Righteous as they seem, however, these entries do not tip the scale but are balanced by factual items. Chieftains, too, have their quota of easy jobs, and as for hard, dangerous and unusual operating, not only are they outfitted and skilled therefor, but they yearn for it. Inasmuch, then, as they bid for it, they should willingly pay the toll. On the

other side of the sheet yeomen not at all rarely find themselves of a sudden faced with most difficult operations. There is no forecasting of surgical hazards. What gives every promise of simplicity may easily prove to be otherwise. And there is no turning back, yeomen have to meet the problem, solve it as best they can and let the chips of mortality fall unbegrudged wheresoever they may. If, forewarned, they choose to dump their desperate jobs onto others, they do but show a wisdom that acknowledges their shortcomings, and a stand by their own conviction that needless mortality has no justification.

When the death rates for specific surgical ills are likewise compared, the scales are still pretty level. Mortalities after herniorrhaphies, cholecystectomies and other common as well as rarer ordeals show but a few decimal points in favor of the lords and masters. With the balance sheet running steadily though slightly in the same direction, it was most enlightening to have figures come forth which seem to prove that in one of the commonest abdominal ailments yeomen have the edge. The finding was most pleasing, too, for surgery today suffers no more stinging rebuke than its showing in appendicitis. All vital statistics vouch beyond peradventure that more people are now dying of appendicitis than ever before. Lay scribes are featuring the ill turn of appendiceal mischief with now and then an air of grim and only half-hidden content. In sober vein, current medical writers bewail the blemish on surgery's escutcheon, but are seemingly at odds with one another over what to do about it. It should be noted, however, that the authors of the surgical lamentations are the leaders in big metropolitan hospitals, the heads of large clinics or their hand-picked lieutenants. The experience of chieftains is so vast it is sort of taken for granted that the results of all others are the same. Of late, however, several surgical yeomen have challenged this inference, and as yet it is not recorded that the gauntlet they threw down has been taken up. Their case rests on figures from three sources: federal records of vital statistics, reports from twelve large clinics and accounts from twenty small hospitals. For the whole country the general death rate of appendicitis hovers from year to year around 3 per cent, for appendectomy in acute and non-perforated cases it is 4.8 per cent, but when complicated by peritonitis the rate jumps to 30 per cent. Taking these national figures as mean levels, the challenging yeomen plot some rather upsetting extremes. Whereas the head surgeons list a general mortality for appendicitis of 4.5 per cent, they achieve one of 2.1 per cent. For all acute cases the former con-

less a death rate of 6.8 per cent, the latter of only 3.1 per cent. And when peritonitis adds its horror, the figures are widest apart: 38.5 per cent against 17.7 per cent. Not content with this pleasing triumph, the challengers go on to show that all records award them in the last decade a yearly drop in death rate, a fall which seems to have eluded their big brethren. There they rest their case. With their usual becoming modesty they vaunt no reasons for their better showing, and with forbearance and kindness learned through many mishaps of their own, they hint no causes for the less happy outcomes of others. In a spirit of fair play, and with an equanimity born of facts, they choose to await in calm contentment the issue of rebuttal.

For the hiding of their good works the old guard themselves are most to blame. They have been too busy to write of their doings, too reticent to speak of them. Their lives have been spent in the rough and tumble of the surgical game, which for long they had to play with the odds against them. Year by year through their own pleadings they have awakened their people to the need for better hospitals, and through their own drive they have brought their workshops up to date. More and more have they picked and trained loyal teams of helpers, and by friendly pleas here and not altogether unkindly insistence there, have won over the layman and his doctor to the gospel that patients fare better with teamworkers than at the hands of casual helpers and etherizers. As they have gained these welcomed changes they have rid themselves of many a hindrance, of many a stress, and have come to the height of their skill and wisdom with the right and the freedom at last to use them to the full.

But these thoroughbreds of the family are more than surgeons, they are gentlemen of the first order, kindly and courteous to all, honoring their leaders, gracious toward their fellows, helpful to younger brethren. In them power and modesty walk together, rare companions these days of might and vainglory. Each in himself is the champion American individualist. He is wedded to the old ways of the surgical art, swayed not by oncoming, thinly disguised mass practice. He was reared in the days when sick people were persons, not records, and he never forgets his bringing up. He knows naught, for example, of a pelvic case in Room 26, but in that bed he has his patient, mother of three children aged two, seven and nine, overworked housewife worrying about her home, Mrs. Mary Jones, whose bleeding fibroid uterus he took out four days ago. The kindly,

personal touch is always with him. When his patients go home from the hospital, he does not hand them wholly over to other doctors, but himself in friendly part watches them through the aftermaths of their ordeals and himself handles the petty discomforts prone later to arise. By so doing he has learned little ways to forestall no few of the untowardnesses that operative haste and post-operative inattentiveness inflict. His reward is an easier, shorter recovery for patients than is sometimes won by others who, interested in records more than in persons, hand over their cases at an early date to the mercies of this or that kindly but less adept family doctor.

Gentleman by habit, surgeon by training, by his faith he is sworn guardian of his calling. Fiercely and ready to turn to good account the stupendous gains in surgical knowledge, he stands abashed at the strange ways some people would have that knowledge used for suffering mankind. He wonders at the suave effrontery of outsiders who, with insight dim, would nonetheless tell him how best to handle the ills of the people. With the wealth of understanding that is his from a life soent on the firing line, he knows that, despite the social angles the meddlers stress, the true practice of medicine and surgery is personal and individual. For him that is the solid rock on which his calling was built, and on that firm base it has through the ages grown to stature that commands respect for the doctor, though oft, alas denied the profession at large.

There is good reason to fear that the fate of this race is to be forgotten while here, remembered only when gone. Already there are signs and omens round and about that the order of surgical yeomen and what it stands for are passing. Many a town and urban district are seeing the last of them. Their times and ideals are seemingly outlived, the new day and its values are different.

The old order changeth, yielding place to new,
And God fulfills Himself in many ways,
Lest one good custom should corrupt the world

Without going into the causes thereof, the surgical craft is being more and more split into specialties. The division of labor without any doubt makes for better surgery, but whether it also makes better surgeons may be questioned. More soundly taught and more sharply trained, the new order has greater learning. Whereof the old-timers, with only long-tried empirical lore, had to guess shrewdly, — though usually right, — the newcomers speak with scientific certainty. Yet somehow the cold, sober logic lacks the warm personal touch of the yeomen. Mayhap the latter did now and then

with their manner and speech cloak their ignorance, but they did therewith spread "air and cheer" in the sickroom. Worried parents and relatives do after all like their draughts of science sweetened with human kindness.

Though surgeons of the hour are more deft of hand than their yeoman sires, each is apt to be so only in his chosen and narrow field. And he sticks pretty close to his own bailiwick, whose no-trespass signs he would have heeded as he himself heeds others all about him. On grounds other than his own he does not feel at home, and therein is his weakness. Specialties overlap, and many a borderline illness straddles a surgical line fence. Does a man with a broken back and some signs of cord mischief belong to the orthopedist or the neurological surgeon? If given into the hands of one, the patient may later develop symptoms that call for the skill of the other, whereupon the first expert has either to call upon the second for aid, which sometimes, alas, is honest clash of opinion, or himself muddle along as best he may. The victim must then either swap horses in the middle of the stream, risk his welfare to a balky team or chance a floundering. It can scarce be maintained that any of these choices grants the sufferer the faith in his surgeon and the peace of mind for himself that lessen worry and make for kindly outcomes.

Every year brings forth new measures of organic function, new tests for disease, new mechanical aids to sight, hearing and touch. Scientific beyond all peradventure each and every one of them adds to better understanding of disease, but for a single patient any one of them may easily be misleading. Each is focused not on the whole of any one disease, but on just one, perhaps small, aspect which it may overilluminate. Despite this and other forewarnings, however, newly trained surgeons show a tendency to overrate now one and now another promising but unseasoned helpmeet. Seemingly too they oftentimes lack the faith of their fathers in the findings of their own eyes, ears and fingers, and put their trust rather in new-found guides who, though meaning well, sometimes lead them into grievous error. And scientific though the guidance be, it is not firsthand. For the most part the handling of such measures, tests and aids is beyond the ken and scope of clinical surgeons and is left perforce to biological chemists, roentgenologists, pathologists and the like. The surgeon thus has to accept not only the findings of these cloistered though earnest workers, but also their reasonings. Instead, then, of a firsthand, clear-cut picture of the patient and his disease, he sometimes finds he has a puzzling clutter of ill-matched,

narrow-field negatives which he must shuffle and strive to fit together

Not so has the surgical yeoman been troubled or led astray. As science came into his life, rarely did it upset his long-trying empirical knowledge. At times it shifted his beliefs a mite, but more often it confirmed them. Long forced to do without scientific helpmates, he had trained his own senses to catch the faintest of untoward signs, had schooled his brain to sift and value all his findings. When a perfected measure, test or aid came forth, his common sense quickly rated it, his well-ordered mind neatly stowed it away, and his wisdom made of it a means and not an end. If his touch told him the broken leg was about the length of the other, the weight-bearing line true and the ends of the bone in good contact, he was not to be rushed into resetting because x-ray showed that the fragments were not meeting wholly end to end. Nor did he dally with acute appendicitis because the white-cell count was not high. The way a man lay in bed, the look on his face, the strength of his voice and handclasp, the cry and grunt of a sick child, the stare of a tearless woman, these and countless other like signals of distress told him at a glance things about his patient no test tube or microscope can ever reveal. It was not playing hunches, it was not just intuition, and it was not snap guesswork, it was free play of his wisdom. Often hard put to rationalize his opinions, he was sometimes wholly stumped for explanations. He had seen these things many times and had come to know what they meant. He knew human bodies, their modes of expression, their moods of behavior, and what they signified, and above all he knew human nature and was seldom to be fooled by its vagaries. Not that he frowned on laboratories, quite the contrary, he was deeply grateful for all they taught him about disease. He turned to them often and gladly for needed help, valued their judgments but did not let them confuse him. When their reports confirmed his opinion, he was heartened for his patient's sake, but when they ran counter to his clinical reasoning, again and again reviewed, he put his trust in his own long-trying senses, which had rarely led him far astray.

They have had full lives, these surgical yeomen. For some, toil is over. For many more, years of labor are numbered. Plenty are the omens that this old guard is passing, that many a town and urban district are having their last good general surgeons. Gloomy forebodings notwithstanding, faith in surgical yeomanry's ideals still lives. Remnants of the order, scattered and unorganized,

tend the hallowed light and keep it burning. Here and there bands of the faithful are heartened by tokens of an awakening that holds forth promise for their order. Far in the offing are faint rumblings of discontent with some of the surgical fashions of the day, rumbles that seem to be growing in volume. Grumblings against overspecialization are making themselves heard in high places where heed is being given to thoughtful critics. Only partly muffled are plaints that chairs of clinical surgery might best be held by teachers who, well bred in family bedside manners, would drill their pupils in the art as well as in the theory of practice, and would show them how to treat not just sickness but sick people too. Less and less withheld are discreet whisperings of family doctors that when in need of counsel they are finding in one good surgical yeoman the common sense, the help and the cheer for themselves and their patients that surgical specialists with all their scientific learning so often fail to bring. It is unlikely, however, that these and other voices from within the realms of medicine will do for the cause as much as will future uprisings of laymen. Hushed for now, but some day to be loud indeed, will be the cries of disillusioned men and women against the regimentation and mass practice which social and political meddlers seem about ready to impose. Until that public awakening dawns, the old guard can with patience and kindly forbearance await its coming. Then perchance will yeomen come into their own again. Then will their thinned ranks be recruited, and the blessings, the honored ways and the sterling ideals of surgical yeomanry be saved.

Meanwhile a new order holds sway. It is quite different from the old and has a different touch. It seems destined to do better surgery, but whether its workers will be better surgeons only the years can tell. To those who know the old order best, its passing, together with its standards of service, brings a tinge of sadness and misgiving. Mayhap yesteryear, when their fathers were dying, like doubts were held about this old guard then untried, and by the same token the new order may tomorrow prove today's fears ungrounded too. Just as a heedless world has only of late paid tardy acclaim to its pioneer surgeons, so will it likely be years hence before it bestows equally merited praise on its yeomen. In some future age, when the idea of ruling the world according to the whims of a fanciful social conscience has run its bewildering course, and when individual consciences have come again to the fore, then will there be wishful return to some of the good old

ways of yore. And in that new age may another Stevenson be inspired to extol at long last the passing old guard of today. Until that time comes, this heartfelt tribute is paid them by one whose

lasting joy and satisfaction will ever be that the rich and happy years of his professional life were spent at the side of a surgical yeoman
33 School Street.

THE RELATION OF NEWER DRUGS TO PUBLIC HEALTH

G PHILIP GRABFIELD, M.D.*

BOSTON

THE topic assigned to me presents an unusual aspect of pharmacology, though this science, like public health, maintains contact with all other fields of medicine. The recent tragic deaths from the use of diethylene glycol as a solvent for sulfanilamide have emphasized the relation between medicaments and the public health. Indeed the sciences of pharmacology and of public health are allied in type. Both, by their nature, have not developed technics *sui generis*, but use the methods of all the medical sciences directed toward certain goals, defined by the point of view from which each approaches its problems. Pharmacology focuses the separate technics which it uses on the elucidation of the qualitative and quantitative effects of drugs on the animal and plant body and the mechanism of such action as may be produced, similarly public health directs its efforts toward anything that concerns the welfare of our citizenry.

A discussion of the relation of public health to newer drugs necessarily concerns itself with methods of treatment and is a part of the more general topic of the relation of the public-health authorities to the practice of medicine and to the manufacture and dispensing of drugs. Pharmacology in the medical school concerns itself or should concern itself with preparation of the medical student for the use of drugs as tools in his hands for the cure or comfort of the patient. At this period of the student's career the discussion of proprietary remedies, patent medicines and over-the-counter self-medication should be emphasized. Expansion and reiteration of this teaching in the clinical years of the medical school and in the field of preventive medicine is necessary, but is deficient in most schools. After graduation it should become the concern of the legally constituted health authorities to keep the physicians under their jurisdiction continually conscious of these pitfalls of therapeutics. In this the help of graduate schools of medicine should be enlisted. Lack of such teaching increases the burden of the health authorities in their efforts to safeguard the public health. Education, continuous and unremitting is the only

practicable method of breaking down the hold that proprietary medicine has upon the medical and lay public.

With all the efforts that have been made to prevent fraud upon the public, such as the activities of the Food and Drug Administration of the United States Department of Agriculture and of the Council on Pharmacy and Chemistry of the American Medical Association, it has been impossible to provide really adequate legislation. The reason for this is that the problem resolves itself into the simple but thorny one of "truth in advertising," together with a revision of our copyright and patent laws. But a start in this direction has certainly been made. If local health officials can be made acutely conscious of the dangers of the use of proprietary names for common substances, and of secret or semi-secret mixtures, they can do much, even under existing legislation, to diminish these evils by appropriate health education among citizens and physicians.

Six points of contact occur to me at which pharmacological advice becomes essential for adequate formulation of recognized public-health activities. These are as follows:

The supervision and adequate testing of new antiseptics and germicides

An evaluation of the drugs introduced for the treatment or cure of contagious diseases

The maintenance of high standards, both in manufacture and in dispensing of drugs

The investigation of the toxic manifestations of drugs, whether exhibited in suicide, homicide or accidental death

The determination of industrial hazards from chemicals, and investigation of the use of various toxic substances in the treatment of foods

The control of the use of new drugs or new mixtures which may appear on the market without adequate clinical trial

It is evident that these six items involve the whole question of the relation of public health to the practice of medicine. The problem reduces itself to the question of how far the governmental health authorities should intrude into the field of practice. In the evolution of our present state departments of public health it is undeniable that the state has invaded the domain of medical practice to

Read before a meeting of the Massachusetts Public Health Association, Boston, October 28, 1937.

Associate in pharmacology, Harvard Medical School; associate in medicine, Peter Bent Brigham Hospital.

a surprising degree. Mental diseases, tuberculosis and cancer are essentially part of our public-health set-up. Serums and vaccines are made in state laboratories, and their distribution and administration are controlled by state health departments. In Massachusetts one drug is even manufactured by the State. That these developments will proceed further as time goes on seems inevitable. Whether we will or no, we are destined to an increasing development of governmental influence in matters of public health, what is even more significant, more and more subjects are going to be the concern of public-health officials. If this prediction be correct, what is the direction in which we should guide this development so far as it may concern pharmacology and drugs in general? The valiant efforts of the United States Food and Drug Administration and the Council on Pharmacy and Chemistry point the way. Constant education of the doctor and through him the lay public is the method chosen by the council. The Food and Drug Administration has been alert to pounce upon every violation of the law, defective as it is, even if the violator seemed unimportant so far as the extent of his operations was concerned. The tendency of many departments of public health, on the other hand, has been to expand facilities for medical care, when public education directed toward eliminating the waste of money on patent medicines might almost make unnecessary the provision of additional facilities for the "medically indigent." All the reports on the cost of medical care indicate that as much is spent in the United States for patent medicines as for all other types of medical service combined.

A first and most constructive step would be to remove from the class of medically indigent those who spend their hard-earned wages on patent medicines. How may this be done, and how does it concern public-health officials? It may be effected in two ways by education and by legislation. It is a paramount duty of health officials to teach the public the stupidity of self-medication, the evils of proprietary drugs and the dangers of patent medicines. The only agencies that have courageously attacked this problem are the Council on Pharmacy and Chemistry and the Food and Drug Administration, the latter is hampered by being a governmental agency. It is sad to see the lack of support in this vital campaign that is exhibited not only by the rank and file but even by the leaders and teachers in medicine, including those who hold advanced social views on the place of medicine in the body politic. These are the ones who perpetuate the use of proprietary names and thereby double the cost of medicine to their patients—money that could be used to relieve

the medically indigent. An indirect effect of this practice is the encouragement of self-medication and the consequent establishment of a relation between druggist and patient that indirectly makes the latter easier prey for the patent-medicine advertisement.

It seems unnecessary to emphasize this further. Illustrations will readily come to mind. Recent events have emphasized the great importance of adequate control of the marketing of newer drugs. Conscienceless manufacturers may introduce toxic substances without hesitation, and it is only by constant vigilance that public-health officials can prevent tragedies such as have lately occurred through the marketing of diethylene glycol as a solvent for sulfanilamide. The Food and Drug Administration and health officials throughout the country are to be congratulated on the rapidity with which they have traced all shipments of this nefarious mixture.

Mention of this incident suggests sulfanilamide as the most important single drug for discussion here. This substance has an interesting history in that it throws light on the practices that are perhaps not unknown in this country. The first reports of sulfanilamide were clinical ones made in 1933. The first experimental evidence that this substance was effective against streptococcal infections in mice was published in 1935, and the dosage then reported was not even remotely adequate according to later experiments. The chemical as originally introduced was complicated, and was protected by patent. To Marshall* belongs the credit of seeing immediately that the active agent which is split off from the compound in the body is a comparatively simple substance, sulfanilamide; it was first made in 1903 and consequently is not patentable. This rapidly supplanted Prontosil and Prontylin.

The introduction of this substance as a therapeutic agent illustrates another point where pharmacological advice is of value to the health officer. If his function is to advise the physicians of his district about new drugs, he can often secure information of possible dangers before clinical examples are recorded. In the case of sulfanilamide, there was a strong indication from the chemical structure of the drug that hemolytic effects should be guarded against, and likewise that granulocytopenia was a possible toxic manifestation. Changes in the hemoglobin were suspected as possible complications of its use. All these predictions by those familiar with the relation between physiologic action and chemical constitution have been borne out by subsequent events. It is interesting that some change in the color of the blood, the cause of which is not wholly clear, is an accompaniment

of adequate treatment. A new drug falls into disrepute, often undeserved, because of inadequate dosage, improper administration or use in improper cases. Briefly, at the present time, the indication for the use of this drug is in infections with the hemolytic streptococcus, the meningococcus and the gonococcus, and possibly in Type III pneumonia. It is common to find that it is tried, usually in inadequate doses, for all sorts of conditions which bear no relation to its now fairly well-established effectiveness.

As to the method of administration in adults, sulfanilamide should be given in divided doses totaling 3 to 5 gm. per day, preferably with an equal amount of alkali, or somewhat less, in the form of sodium bicarbonate, to avoid depletion of fixed base. Because of its activity in an alkaline medium it may be found to have some use as a urinary antiseptic in cases in which it is difficult to change the reaction of the urine to the acid side, and in certain types of urinary infection. It is apparently valueless against ordinary urinary infection with the colon group of organisms, which may be effectively treated with another newly introduced drug, the ammonium salt of mandelic acid. A definite public-health problem is involved in the use of sulfanilamide in the treatment of gonorrhea. With our lax laws it will unquestionably be sold freely for self-medication. It is conceivable that inadequate self-treatment may cause a tremendous spread of this disease. Certain symptoms associated with the administration of the drug may simulate mild alcoholic intoxication in ambulatory patients and thus provide a public menace in relation to the automobile.

Elixir of Sulfanilamide was produced by the S. E. Massengill Co., a pharmaceutical concern in Tennessee. The sulfanilamide was dissolved in diethylene glycol, and the results of its use provide a better experiment in toxicity than is usually seen in pharmacological laboratories, the recorded deaths constituting 100 per cent of those taking the mixture. The marketing of this preparation was absolutely indefensible, since it was shown in 1930 that the toxicity of diethylene glycol was approximately that of wood alcohol. Apparently, this mixture was distributed for sale not only without being tested but without even a casual investigation of the literature on the part of its makers. This ghastly experience indicates the danger of combining drugs in therapy without adequate pharmacological control of the mixtures, and the crying need for adequate legislation to control the marketing of all medicinal substances. Under the present law the only liability of this firm lies in connection with the use of the word "Elixir," which is defined as an alcoholic solution. In other words,

the firm cannot be indicted for manslaughter but only for misbranding.

Owing to limitations of time, I can do no more than touch on certain other drugs of particular interest to public-health authorities. In the malarial field, Atebrine, an acridine derivative, is valuable in destroying the asexual forms of the parasite. However, disturbing mental manifestations have followed its use. Plasmoquin, more closely related to quinine, has also been introduced as a complementary substance since it destroys the sexual forms. The use of ammonium salts of mandelic acid in pyelitis has proved very effective against the colon-typhoid group of organisms. Here again we must follow strictly the directions in the administration of this drug in order to get the results which have been obtained in the best hands.

It would not be satisfactory to conclude this brief survey without mentioning the pentavalent arsenicals such as Tryparsamide, Bayer 205 and Fournau 309. These were introduced against African sleeping sickness and would appear to be of little use in Boston but Tryparsamide has been found very effective against syphilis of the central nervous system, and since the Commonwealth of Massachusetts manufactures and furnishes arsphenamine, it may be that a compound similar to Tryparsamide may some day be distributed by the State.

Two other arsenicals of considerable importance to public health have recently appeared. Stovarsal, originally used for the treatment of amebic dysentery, is said to be valuable in the treatment of Vincent's angina. This disease presents a definite public-health problem, spreading largely through restaurants. Here is a distinct field for public-health authorities, in conjunction with pharmacologists, bacteriologists and clinicians, to investigate a substance that appears to be effective in a condition which is widespread and a source of economic loss.

A similar compound of arsenic, Carbarson, has been found sufficiently effective in amebic dysentery to merit a place with emetine. This disease, since the epidemic occurring at the time of the Chicago World's Fair, has become a problem of public health all over the country. Three other substances, Chiniofon, Vioform and Yatren, all chemically related to quinine, have also been introduced to combat amebic dysentery. The relative value of all these drugs is under discussion at present, and this attempt at evaluation should include the active participation of health departments with pharmacologists and clinicians, in order that the spread of this disease may be halted by adequate therapy.

I have given enough concrete examples to indicate the points at which the health officer meets

the science of pharmacology. It becomes obvious that the training of the health officer should emphasize this field to a sufficient degree to make him alert to its possibilities, in order that he may promptly seek advice on the many problems which may affect the public health. The health officer should preach constantly of the evils and dangers of self-medication and of the improper use of good drugs by physicians. Sulfanilamide provides an excellent example of the possible dangers of new drugs. It is almost certain that we have in this drug an addition to therapeutics which is of epochal importance, but at the very outset those familiar with the pharmacological literature were able to predict the probability of untoward blood reactions. New remedies introduced by substandard pharmaceutical houses should be carefully scrutinized. District health officers should have readily available adequate directions for the use of new drugs, so

that they may serve as a source of information for physicians in their districts, in the same way that they now see to it that the physician makes proper use of the various serums. Finally, distribution by the State of certain important drugs should be studied, if only as a threat to check the exploitation of the lay and medical public by unscrupulous manufacturers.

Let each of you preach to the public, to the legislators, to the manufacturer and to the practicing physician in season and out of season the necessity for the complete elimination of all proprietary, copyrighted names for medicaments and of all patent medicines. The control of this traffic is a function of government and of all interested in the health of the people. Education in this direction will ultimately by democratic processes force adequate food and drug legislation, eliminate these abuses, and reduce the cost of medical care.

319 Longwood Avenue.

THE MEDICOLEGAL EXAMINATION OF HAIRS

BENJAMIN M. VANCE, M.D.*

NEW YORK CITY

THE examination of hairs and other fibers is an important procedure in criminologic investigation, and deserves serious attention. In an appreciable number of criminal cases, human or animal hairs are a part of the corpus delicti, so that it may be necessary to examine them and appraise their significance as evidence. It is my purpose here to discuss the value of such hair examinations and also to point out their limitations.

A preliminary consideration of the normal hair growth is necessary before entering on this discussion. Hair is a specialized epithelial outgrowth of the skin which occurs everywhere on the human body except on the palms of the hands and the soles of the feet. The portion embedded in the skin is termed the root and that above the surface is known as the shaft, the distal end of an uncut hair shaft ends in a point, but if the tip of the hair has been cut, this end may be blunt, rounded or frayed. In their normal habitat, hairs are continually growing, reaching maturity and falling out, and new hairs are taking their places. In the same scalp, hairs in different stages of development are found side by side and show variations in length, thickness, shape and degree of pigmentation.

The most distinctive part of the hair is the shaft, which consists of cuticula, cortex and medulla.

The cuticula is the outermost covering and consists of one layer of non-nucleated polygonal cells which overlap like the scales on a fish, the free edges of the cells are directed toward the distal end of the hair. If a light-colored hair is examined microscopically in the dry state, the fine, wavy borders of the cuticula become visible. On human hairs, these markings appear as transversely elongated, polygonal figures which are said by some to be narrower than the cuticular markings on the hair of other animals. They have been suggested as an important criterion in hair diagnosis, but in my opinion are not satisfactory for that purpose, as the differences between the cuticular markings in the various mammalian species are not clearly defined.

The most characteristic portions of the hair are the cortex and the medulla. The cortex is the intermediate and the thickest layer of the shaft, and is composed of elongated, spindle shaped fibrils which cohere, they contain pigment granules in varying proportions depending on the type of hair. The medulla is the central canal of the hair, it may be empty or may contain various sorts of cells, more or less pigmented. Examination of the cortex and medulla yields the most reliable criteria in the diagnosis of hairs.

A systematic procedure should be followed in all hair examinations which have medicolegal importance. The person who brings the specimens to the examiner should identify them to him, and a

Read before a meeting of the Massachusetts Medico-Legal Society, Boston, February 2, 1938.

*Acting deputy chief medical examiner, Office of the Chief Medical Examiner of the City of New York; assistant professor of forensic medicine, New York University College of Medicine, New York City.

record should be kept of the date, place and hour of this identification. If the case under consideration ever comes to trial, the evidence cannot be presented unless the hairs can be properly identified.

The next step is to examine the specimen with the naked eye or with a hand lens. The number of fibers should be noted and their length should be determined by actual measurements. When specimens contain a large number of fibers, the examiner should measure a sufficient number to determine their average length. The color, texture and other characteristics should be noted, and also any abnormalities which may be present.

The hairs should then be examined under a microscope in the dry state. If the strands are lightly pigmented, the cuticular markings are as a rule visible, and their character may be noted. The nature of any foreign substance which may be adherent to the hair shaft should be determined.

After this, the hairs should be cleaned with alcohol or some other solvent and mounted on a slide in xylol balsam. The nature of the specimen will determine the way in which this should be done but a set of rules cannot be devised to meet the problems set by every conceivable case. However the mount must be so prepared that the distal and the proximal ends of the hair can be examined and the general shape, thickness and characteristics can be ascertained without difficulty. The diameter of the shaft may be measured with a micrometer eyepiece, but I agree with Glaister¹ that the importance of such measurements can be overrated, inasmuch as the diameter varies considerably not only in different hairs in the same scalp but at different locations on the same hair. More reliable information can be obtained by comparing the hairs in the specimen with other human hairs in a collection.

Cross sections of hair are especially valuable and should if possible be made of every specimen, except in cases in which it is more desirable to preserve the whole mount intact. The most useful technic for this purpose is to wash the specimen in 95 per cent alcohol for five or ten minutes, to steep in a 10 per cent aqueous solution of sodium hydroxide until the hair is softened sufficiently, to wash in water a few minutes, and to place in 95 per cent alcohol for ten minutes. The length of time in which the hair should be softened by the sodium hydroxide must be determined by the experience of the examiner, but generally when the hairs show signs of losing their natural elasticity they should be removed from the alkaline solution. The hairs are now mounted for sectioning on a small cubical block of liver tissue which has been kept in acetone. A small slit is made in the cube

of liver along the length of one side, and the hairs are straightened out in the bed of this incision. The liver and the hairs are transferred to clove oil and allowed to clear, they are then embedded for twenty-four or forty-eight hours in celloidin which has been dissolved in equal parts of absolute alcohol and ether. The cube of liver tissue is placed on a wooden block in such a way that the slit and the hairs stand upright, and is then hardened for thirty minutes in a bath of chloroform. Cross sections of the liver and the hairs are made by the sliding microtome, and the sections are cleared in carbol-xylol and mounted unstained on a slide in xylol balsam.

Examination of such hair sections will determine the shape of the shaft in cross section, the relative size of the cortex and medulla, and the character and distribution of the pigment in the cortex. This procedure has the advantage of allowing several individual hairs to be examined in the same microscopic field. It is even possible to examine the same hair in whole mount and cross section by removing a piece from the whole-mount slide after the examination and sectioning by the process described above. A valuable method for comparing whole mounts or cross sections of hair is to join two similar microscopes with a comparison eyepiece and examine the specimens in the same ocular field. Photographs can be taken of the different specimens at the same magnification, which is an excellent and convenient method of demonstrating similarities of and differences between hairs from several sources.

An attempt should be made to answer the following questions in every hair examination: (1) Are the fibers hair or some other material? (2) If they are hairs, are they human or animal? (3) If they are human hairs, what is the race, sex and age and from what area of the body were they taken? (4) Is there any abnormality of the shaft, tip or root? (5) Can the hairs be identified as from a certain individual?

It is a comparatively simple matter to distinguish between hairs and other fibers which might be mistaken for them, such as cotton, wool, silk or straw fibers. All these materials present characteristic appearances of their own under the microscope, and any observer who is familiar with hair is not likely to confuse it with fibers of other types.

Animal hairs in most instances can be distinguished from human hairs if typical specimens of each kind are available for comparison. The diagnostic features are most suitably demonstrated by cross section, especially when dealing with dark hairs. When cut in this plane, human hairs present a circular, ovoid or almost flat outline. The medulla is smaller in comparison with the thick-

identity In one such case, a woman of advanced years held in her hands a tangle of gray hair which probably came from her own head, and a single light brown hair which was certainly not her own The hair of the defendant was similar to the single light brown hair, but the limitations of the examination would not permit any positive statement to the effect that they must have had an identical source The other evidence in the case was convincing, however, and the prosecuting attorney was able to propound a hypothetical question which limited those at the scene of the crime to the deceased and the defendant Under such conditions it could be stated with reasonable certainty that the brown hair in the hand of the deceased came from the head of the defendant because of its similarity, and did not come from the head of the deceased because of its dissimilarity

* * *

In general, the evidence which results from hair

examinations must be regarded as confirmatory, and should never be used unsupported by other proof The circumstances in each individual case must determine how valid will be the facts elicited from the hair examination

The most fitting person to perform examinations on hair is a medical graduate or a biologist of wide experience The study of hair is a specialized branch of histology, and of such complexity that long and painstaking application is required to master it It is important that the scientist engaged in this pursuit should prepare numerous specimens of human and animal hairs, both in whole mount and in cross section, and should make photomicrographs of the most typical specimens for the purpose of ready comparison

PROGRESS IN DIABETES MELLITUS

HOWARD F. ROOT, M.D.,* AND ALEXANDER MARBLE, M.D.†

BOSTON

IN this article, it is our purpose to summarize the literature which has appeared since the review in the sixth edition of Joslin's *Treatment of Diabetes Mellitus* (Lea & Febiger, 1937) and in Chapter V of *Nelson Loose-Leaf Living Medicine* (Thomas Nelson & Sons, 1937)

INCIDENCE AND MORTALITY RATES

The number of persons with diabetes in the United States is growing This can be explained first by the increasing duration of life of the diabetic, which is perhaps the greatest factor, secondly, by the steady and rapid lengthening of life of the total population, the age at death being 41.9 years in 1920 and 48.7 years in 1930, thus approaching the ages of maximum susceptibility to diabetes, fifty-one for males and fifty-five for females, and thirdly by the wider recognition of the disease Urban rather than rural life, greater availability of food and reduction in physical exercise are more doubtful factors Evidence from two other sources indicates that there are more living diabetics about us today than ever before, that is, there has been a marked increase in the sale of insulin and of syringes, particularly those designed

for diabetics The estimate of the Metropolitan Life Insurance Company and the authors early this year was that there were between 400,000 and 500,000 individuals in the United States with diabetes, but all will agree that until new methods for the prevention of the disease are known these figures will rise

The proportion of new diabetics to total admissions to hospitals is cited as proof of this increase Such reasoning is not wholly logical unless one takes into account the decrease in contagious cases and in diseases more frequent years ago, balances with it the increasing tendency of patients to enter hospitals for diabetic schooling rather than for disabling illness, and bears in mind that two decades ago the patient lived only four or five years and now lives twelve or more, and so has six or seven more years in which to be counted as an admission to one or more hospitals

Diabetic mortality figures show increases both absolute and relative The figures per 100,000 for the United States changed from 16.0 to 19.0 to 22.2 for 1920, 1930 and 1935, respectively However, as indicative of what we may expect in the future, we cite Hoffman's rates of 21.4 per 100,000 for 184 selected American cities in 1930 and 27.8 for 187 cities in 1936 The rate for the five largest cities in 1936 was 31.2, for Boston in 1935 it was 35.0, and for New York City in 1936 it was 34.9 In four-

*Instructor in medicine, Harvard Medical School, physician, New England Deaconess Hospital.

†Assistant in medicine, Harvard Medical School, physician, New England Deaconess Hospital.

teen Canadian cities in 1936 the average rate was 160, as compared with 13.3 in the Canadian registration area in 1935. Just as one can predict that the death rate of the country will approach that of the larger cities, so too can one feel confident that the rate in other countries will approach that in the United States. In fact, this change is proceeding most rapidly where the original rates were lowest. Italy as a country and Saskatchewan as a province of Canada show this equally well, as pointed out by Chase. She also finds that the distribution by decades of onset of the disease in Saskatchewan among her private cases is essentially the same as in New England among the authors' clientele, thus showing independence of environment. She reports that no case of diabetes was ever found among 1500 Indians whose urines were examined, and that the Inspector of Indian Affairs in Saskatchewan has never heard of a case of diabetes in a pure-blooded Indian. Teleky also has recently shown that the diabetic mortality rate for women in Prussia rose from 0.74 in 1877 to 8.1 in 1914 and to 19.2 in 1932. No doctor can afford to neglect serious study of the diabetic problem, because there are so many diabetics and they live so long.

Hoffman writes, "It is regrettable that diabetes is not a notifiable disease and that the number of diabetics in this country is only a scientific conjecture." We disagree with this opinion, if for no other reason than that the diagnosis of diabetes is sometimes difficult, especially for immediate decision.

Bolduan believes the low mortality in New York City in 1871-75—2.0 per 100,000—was due more to the non-recognition of the disease than to its rarity and recalls that chemical tests for sugar in the urine were not introduced until 1850 and were not routinely adopted until some decades later. That the rate for females was formerly low he attributes to the detection of diabetes in males through life-insurance examinations, this factor offsetting the actual greater prevalence among females which existed then as now. In this connection, Teleky records the extraordinary mortality rate of 1060 per 100,000 for females between sixty and seventy years of age in Prussia in 1931. We may expect the increase among females to continue for some time, Bolduan says until the rate becomes stabilized at a point which represents approximately the relative prevalence of the disease among the two sexes, he adds that the forty-five-years-and-over group is more than one-third greater than it was in 1900. Since 1900, at least one-third of the increase Bolduan believes to be attributable to the aging of the population. Part of the increase is due to the influx of Jews, in whom he says the disease is 50 to 75 per cent more prevalent. Allowing for these two factors, age and race, the diabetes mortality rate in New York City

among males shows a downward trend during recent years." He considers that 1 per cent of the population of New York City is diabetic and that "it is probably conservative to estimate the diabetics in the United States as over 600,000."

Despite the prevalence of diabetes [he writes], we do not find this disease among the five leading causes of death [in New York City] among males at any age period. It appears in eighth place in the age period 50-55, and does not rank higher than seventh after this. In females, on the other hand, diabetes is among the five leading causes of death at ages 55-64 years, and, after occupying eighth place at ages 40-44, it is never less than sixth place in the more advanced years.

In a recent publication from Washington, the frequency of ten leading diseases in poverty is mentioned, but of them, diabetes is the exception in that it did not progress with the extent of the poverty.

In 1935 diabetes mellitus was responsible for 3 per cent of all deaths of holders of industrial policies of the Metropolitan Life Insurance Company according to a recent report. It ranked ninth among the causes of death in this group, and if accidents and homicides are excluded, it ranked eighth. In recent years (1931-1935) the rate under ten years of age has been less than 2.0 per 100,000, rising to 142.2 for both sexes among white persons between sixty-five and seventy-four and to 305.2 for white women. The rates among Negroes have been less and the increases more rapid. The rate among white women, aged one to seventy-four, exceeded that among the men by 91 per cent, and among Negroes by 112 per cent, but the actual excess is virtually limited to middle and old age. Negroes are as prone to the disease as are Whites, and between the ages of ten and fifty-five the rates for negro women are higher.

For the last four years, the report continues, the death rate from diabetes as a whole has been constant, the maximum for any one year being 20.8 per 100,000. Among young persons, the trend has been downward since the discovery of insulin, with the exception of young Negroes, and here there has been a rise, as in older ages for all.

The increases are explained in part by the greater percentage of older people in the population, thus, between 1900 and 1930 the population at forty-five years or over more than doubled, but the total population grew by only 62 per cent. The female population at forty-five and over has advanced 110 per cent in thirty years. The shift of population from rural to urban centers, and the rapid growth of foreign immigration, including peoples peculiarly susceptible to the disease, have had as results a growing population susceptible to diabetes. The increase in the use of machines, which reduces muscular work, and the rise in the standard of living, are accessory factors, presumably because they

favor obesity. Also of great importance has been improved diagnostic technic. The growth of life insurance has naturally contributed to the discovery of new cases, for 4,000,000 persons in the last few years have annually applied for such insurance, requiring medical examinations, and the number thus insured is now about 30,000,000. Other points brought out are the growing longevity of diabetics especially of children, the reduction in the mortality due to diabetic coma and the shifting of causes of death to conditions incident to the age of the patients.

INSULIN

The use of protamine insulin has become widespread in the United States, largely because of the simplicity and ease of single dosage, making it advantageous not only in children but also in adult patients with milder grades of the disease. In general, those clinicians who have employed it extensively are most convinced of its value. Protamine-zinc insulin is the type authorized for sale and has displaced the original protamine insulin and its various other modifications. Patients hitherto untreated with insulin adopt its use most readily and seldom have difficulties, whether hospitalized or treated in the office. For patients brought up on regular insulin, the transfer to protamine insulin is often confusing, and for those whose meals must vary in time and quantity from day to day it may be impracticable.

Protamine-zinc insulin may act not only for twenty-four hours but in fasting patients for forty-eight hours or longer (Wilder, Sprague and Rynearson). Consequently the action cannot be expected to meet uneven demands such as the peak loads of meals. Similarly, its action is just as strong between meals when the glycogen reserves are lower. Therefore, for successful therapy meals must be spread far apart and luncheons inserted between them and particularly upon retiring, to guard against the night's fast, sometimes, indeed, it is safest to begin the day with the breakfast fruit and protamine insulin simultaneously. Contrasted to the procedure with regular insulin, in which the dose may easily be varied with the immediate needs, with protamine insulin the dose preferably remains unchanged but the carbohydrate may be shifted, as recommended by Ricketts, from one meal to another or the total carbohydrate for the entire day may be raised or lowered. Occasionally such alterations do not suffice and one is compelled to supplement the dose of protamine insulin before breakfast with regular insulin, the dose of the latter varying as a rule from one fifth to three fifths of that of the former. Seldom is the total dose of protamine insulin less than that of regular insulin which the patient may have been using.

Hypoglycemia Reactions to protamine insulin are, as a rule, less severe than is the case with regular insulin. They are usually accompanied by fatigue, nausea and headache along with the typical hypoglycemic symptoms, although the perspiration, tremor and palpitation are less marked. The patient may appear in a semi-dazed state with mental processes depressed. The hypoglycemia at times is asymptomatic, but may lead to marked and severe symptoms if, at such a period, the patient exercises. Symptoms may come on more unobtrusively than those due to regular insulin. At times the patient requires more than one dose of carbohydrate to secure relief.

"With protamine zinc insulin," says Sherrill, "the blood sugars may be maintained at very low levels, namely 0.03 per cent and 0.04 per cent, without symptoms of any kind." Attention is called to the recent experiments of Sherrill and MacKay, in which they report as follows:

Normal dogs die following prolonged hypoglycemia from a single or several injections of protamine zinc insulin. Heretofore it has been generally assumed and recognized that the hypoglycemia resulting from the use of regular insulin has proved entirely harmless if the blood sugar is returned to normal by the administration of carbohydrate or other food. No deleterious, residual injuries have been noted in man or animals. We have found that when fasted dogs are kept in hypoglycemic shock with occasional convulsions for twenty-four hours or more, some organic change is induced which prevents recovery and results in death, even though the blood sugar level is restored to normal and the fluid balance is adequate. We have used 6 normal dogs for experiments and death has resulted in each instance. As a rule, we have given a single injection of approximately a half unit of protamine insulin per pound of body weight. Subsequent smaller doses may be required to produce prolonged hypoglycemia. These dogs have been kept in a stuporous or comatose condition with blood sugar concentrations ranging from 20 to 30 mg per 100 cc. for from twenty-four to forty-eight hours. Carbohydrate was then administered either intravenously or by stomach tube and the blood sugar concentration raised to normal until death ensued. None of the animals regained consciousness. Some tissue or organ is apparently so damaged by the hypoglycemia or related reduction in glycogen content that death ensues, probably due to failure of the vascular system. No gross pathological lesions in the visceral organs or brain have been noted. Further experiments are in progress to determine the mechanism of this deleterious effect of insulin shock and the minimum duration of hypoglycemia which is dangerous.

As to whether the pathological lesions or chemical alterations which cause death in the dog are similar to and can be reduplicated in man is open to question. Nevertheless, the admonition at this time is expedient. Although the above animal experiments are convincing, hasty, adverse conclusions should not be arrived upon which might deprive the diabetic patient of the benefits which might accrue from protamine insulin.

Wilder's experiments with dogs given overdoses of protamine insulin resulted similarly. Multiple

petechial hemorrhages were found in the brain

In the course of studies designed to determine the effects of various diets, hydration, dehydration, and so forth, on convulsions caused by insulin in nondiabetic dogs, Corwin found that if an animal was given injections of insulin on successive days, its resistance to hypoglycemia decreased on the second day and decreased still further on the third. The resistance then became more or less stabilized so that on all succeeding days there was little if any variation in the response.

For clinical reasons Jordan emphasizes the importance of caution to avoid hypoglycemia in elderly diabetic patients who are taking insulin.

A diabetic who has an insulin reaction which puts in jeopardy the lives of others or his own makes it increasingly difficult for diabetics to secure employment, and brings nearer the day when the privilege of driving a motor will involve stricter physical and mental tests. Diabetics must not have insulin reactions, and this is one reason why we are satisfied if we can keep our severer diabetics 90 per cent instead of 100 per cent controlled. By this we mean that there is excreted in the urine no more glucose than 10 per cent of the actual carbohydrate in the diet. For this purpose the formation of glucose out of protein and fat can be disregarded. This paragraph is written apropos of the opinion of the New York judge who discharged a diabetic where the evidence showed he was having an insulin reaction at the time of the accident, but who, on the other hand, took away his license.

Sensitization Swelling and induration at the site of injection of insulin may occur and threaten abscess formation, but the latter seldom if ever develops. After a few weeks these local signs almost invariably disappear, and with the continuation of injections new ones fail to form.

Lewis points out that insulin protein is an active antigen and does not react in common with pancreas protein, that its specificity is independent of that of the major constituents of the pancreas, that it is without species specificity since it has no antigenic activity in common with other proteins of the same species, which are strongly species specific, and finally that insulin proteins from different animal sources are immunologically closely related.

Protein sensitiveness so severe as to prevent the use of insulin has been extremely rare in Umber's clinical experience with 8000 diabetics. Generally, sufficient prophylaxis is given by injecting 4 units twenty minutes before the regular insulin injection. Stötter, from Umber's Clinic, thinks that if he had used the method of Lasch and begun with a dilution of 1:100, the result would have been fatal in his patient, who had a history of protein sensitivity and hay fever in 1916, and sensitivity to

peptone in 1919. An attempt at desensitization almost caused death. In 1931 diabetes was diagnosed, in 1932, following the administration of staphylococcal autovaccine, the patient had an allergic reaction of extraordinary severity, the blood on the next day showing 6,600,000 red cells and 9 per cent eosinophils, in 1933 there were two more reactions to peptone. The patient entered the Umber Clinic in July, 1936, with a urinary excretion of 66 gm of sugar in twenty-four hours and a blood sugar of 280 mg per cent. Desensitization was begun with intracutaneous doses of 0.1 cc of a 1:1,000,000 dilution, but the reaction proving positive, with marked local and later general symptoms, the dilution was changed to 1:10,000,000,000 and was gradually increased. The patient was kept on a protein-free diet for about a month. Within one month he could take 0.5 cc. of a 1:1000 dilution. After two months the diabetes was controlled with 12 units twice daily. Special precautions were taken to preserve the crystalline insulin used, to keep it free from contaminating protein. Eventually the patient was wholly desensitized against insulin, and incidentally, peptone sensitiveness also disappeared.

Methods A multitude of articles upon protamine-zinc or calcium insulin has appeared. Joslin summarized and commented upon his results in over 1250 cases. Emphasis was laid upon the desirability of reverting to the Naunyn era and comparing carbohydrate intake with glucose loss. If with modern diets containing 150 gm of carbohydrate only 10 per cent, or 15 gm, appears in the urine, the case can be considered fairly well controlled. With complete sugar freedom, there is danger of reactions unless the days are planned with remarkable uniformity. The zeal of patients to keep sugar-free throughout the twenty-four hours, however, is a welcome contrast to their former indifference to their tests.

Wilder demonstrated the importance of insulin in protecting the proteins of the body from catalysis. This may account for the better health and apparent increase in carbohydrate tolerance of patients taking protamine insulin. Wilder also found an initial dose of protamine insulin along with regular insulin of decided value in the treatment of diabetic acidosis.

Most writers, including Sherrill, stress the better control of patients under protamine insulin and its value in reducing hepatomegaly. Greenhouse also noted improved carbohydrate tolerance, which he quite correctly writes "may be ascribed to the stabilized carbohydrate metabolism made possible by the continued insulin effect maintained by protamine zinc insulin." Richardson gives good working rules for its employment.

Humsworth finds that the new protamine insulin compounds act so slowly that they are ineffec-

tive in suppressing alimentary hyperglycemia, and that it is therefore often necessary to give auxiliary injections of quickly acting insulin

Evidently Whitehill and Harrop have realized the difficulties of protamine insulin for the careless or erratic diabetic, for they write "Individuals with moderately severe diabetes who will not submit to a careful, regular dietary regime will find the use of regular insulin safer and, on the whole, more satisfactory." They also note the variability and unpredictability of its action. Gray, Bischoff and Sansum report favorable results with histone insulin, which because of its slow and prolonged action they consider particularly useful in patients with severe diabetes, in juvenile patients and in elderly ones with cardiovascular complications. No local or systemic reactions were noted. The total unit requirement was the same or less than that with regular insulin. Instead of 27 injections per day of regular insulin, the number has been reduced to 1.2 injections of histone insulin.

With children especially, says Joslin, protamine-zinc insulin has been welcomed, although with the large majority, regular insulin has also been necessary. Newcomb, Dick and Schnute urge the importance of adjusting the meals and carbohydrate intake so as to prevent reactions when children are taken home from the hospital. Children were said to have fewer periods of intense hunger than adults and to be more active and alert. Favorable results with children were noted also by Drysdale, who believes protamine insulin especially efficacious in preventing diabetic acidosis in juvenile diabetic patients suffering from respiratory infection.

According to Sindoni, "protamine insulin, if indicated, should be given on retiring and, if necessary, after breakfast, immediately following the ordinary insulin, which is given within from fifteen to twenty minutes after meals."

Resistance From time to time, cases have been reported which have shown most of the symptoms and signs of diabetes but which did not respond to insulin in the usual fashion. An extraordinary case treated by Mason and Sly was that of a white boy, twenty-five months old, who was found routinely to have low fasting blood-sugar values and who exhibited glycosuria and an abnormal rise in blood sugar following the ingestion of dextrose-containing carbohydrate. The ingestion of isocaloric amounts of levulose or galactose, or large amounts of protein or fat, caused much less rise in blood sugar and little or no glycosuria. The patient exhibited little or no response to insulin. The glycosuria could always be stopped by the substitution of levulose or galactose for dextrose in the diet. The authors suggest that the difficulty in this case was caused by a marked lessening of the liver's ability

to convert dextrose to glycogen or to an intermediary product in this conversion.

Himwich and Fazekas hold that resistance to insulin is developed during infections. The effects of the disease in stimulating the endocrine glands and the nervous system result in a rise in blood sugar, counteracting the effects of insulin, whether endogenous or injected. It is the infection, not fever, that is the potent factor in the development of insulin resistance. Insulin resistance, experimentally produced by diphtheria toxin injections, results from an increased activity of the sympathetic nervous system which favors glycogenolysis. Insulin resistance does not appear to be due to antibodies, for antitoxin creates no insulin resistance. The mobilization of carbohydrate in response to the emergency of infection, although ordinarily a defensive reflex mechanism, becomes injurious in diabetes. Thyroxin and the anterior pituitary hormone also counteract effects of insulin. Diphtheria toxin exerts a direct necrobiotic effect on the islands of Langerhans and the cells of the liver. The chief factor in insulin resistance, however, is hormonal antagonism. Ergotartrate in large doses may inactivate the mechanism of insulin resistance. Denervation of the adrenal gland is not to be considered. Combating the infection is the most logical treatment. Standard insulin, with its more intense and rapid action, is preferable to protamine insulin in cases of acute infection.

Technical Sahyun, Goodell and Nixon found that a preparation of insulin low in ash and free of copper, iron and zinc was unstable when incubated at 52°C for at least one week. At the end of nine weeks' incubation at this temperature the insulin had lost 50 per cent of its physiologic activity. However, 1 mg of zinc to every 1000 units resulted in a preparation which was quite stable at a temperature of 52°C for seven weeks, and at the end of nine weeks' incubation at this temperature the sample had lost only 10 per cent of its physiologic activity. The addition of zinc in the amount of 1 mg to 1000 units did not cause either a delayed onset or a greater duration of the hypoglycemic effect of the insulin.

Miscellaneous Kantrow and Boyd gave 0.25 units of insulin per kilogram of body weight to children and determined the blood sugar before and at half-hour intervals afterward. In the non-diabetics the maximum fall in blood sugar occurred in the first half hour, whereas in diabetics the effect was prolonged.

Major and Delp found in tests carried out on both rabbits and human patients that inconstant but at times marked decreases in blood sugar might follow the cutaneous application of insulin.

HYPERINSULINISM WITH PANCREATIC TUMOR

White and Gildea report the case of a woman of thirty-two with symptoms of hyperinsulinism which were shown subsequently to be secondary to an island-cell adenoma of the pancreas. This adenoma was unusual in that it was calcified and was found outside the pancreas in the surrounding tissues. Before the operation it was noted that the patient responded more favorably to a high-carbohydrate, low-fat diet than to a low-carbohydrate regime. The threshold for the development of symptoms of hypoglycemia was not appreciably affected by the administration of large amounts of alkali or acids. No direct relation was demonstrated between emotional tension and the onset of symptoms.

Herrmann and Gius report the case of a man of forty-eight who suffered attacks of spontaneous hypoglycemia. The striking feature was that at operation instead of a pancreatic adenoma or a calcareous mass was found. No pancreatic tissue was found by the pathologist in the material removed at operation. Careful studies at intervals following the operation showed entirely different glucose-tolerance tests than before operation and the symptoms of the hypoglycemia did not recur.

DIET

The problem of diet continues to be discussed from the point of view of the etiology of diabetes as well as from that of therapy. Bertram emphasizes the use of high-carbohydrate, low-fat diets. He, like Süsskind, believes that the increase in diabetes is due to increased consumption of fat by civilized man and to obesity itself. Of the men who were 25 per cent overweight, 49 per cent owned an automobile and therefore took little exercise, and 74 per cent were guilty of greater or less abuse of alcohol. However, in 49 per cent of his cases there was diabetes in the family. An important point is that Bertram believes that the occurrence of diabetes is not conditioned by the hereditary anlage but is in reality due to exogenous factors.

Vesa studied 23 diabetic patients between the ages of seventeen and sixty-five. Blood and urine samples were examined for sugar hourly from 8 a. m. to 8 p. m. on successive days. He found that the taking of pure olive oil did not in any case cause an elevation of the blood sugar higher than the control sugar curve obtained in fasting, in fact, in some cases the blood sugar fell during the course of the day more rapidly than during a similar period when fasting. Furthermore, the amount of sugar in the urine was often smaller when fat had been taken than when the patient had had nothing to eat.

After the taking of meat the daily blood-sugar curve almost paralleled the fasting curve, although in some cases it was on a slightly higher level. The giving of meat did not cause any hyperglycemia, it merely caused the blood sugar to fall more slowly in some cases when compared with the fasting curve. The amount of sugar excreted in the urine after meat was somewhat greater than that during the period of fasting.

The author concludes that fat and albumin probably affect metabolism during the course of the entire day and that the ingestion of pure fat and albumin does not need to stand in any direct relation to the time of insulin medication.

The relations of the vitamins to carbohydrate tolerance must be considered of some importance since, as Umber points out, both vitamins and hormones act as catalyzing agents which regulate chemical changes in the living cell. He emphasizes the fact that one may have a purely functional disturbance in the pancreas gland of a most serious nature without any demonstrable pathologic change, not merely in relation to diabetes but in relation to the other functions of the pancreas. He illustrates this with the case of a woman of fifty-four who suffered loss of weight and fatty stools, with a loss of 75 per cent in ingested fat in the stools, development of aplastic anemia and at autopsy an entirely normal pancreas. Similarly, this condition of the pancreas can be produced in hyperthyroidism. He holds that diabetes almost never follows an infected, necrotic pancreatitis unless there is a constitutional deficiency. He cites a case, however, in which he believes that diabetes did follow some years after an acute gangrenous pancreatitis in a woman of twenty-six. He believes on clinical grounds that functional inflammatory or neoplastic lesions in general affect only the external secretion of the pancreas. The island apparatus is extremely resistant against all exogenous pancreatic injuries unless there is a constitutional deficiency.

A direct connection between diabetes mellitus and vitamin A is unknown, according to Schroeder. Carotene, as well as vitamin A, is found in diabetic blood serum, but during diabetic coma both disappear. In view of the antagonism between vitamin A and thyroid secretion, it seems likely that carbohydrate metabolism is indirectly influenced by vitamin A. Although vitamin B has no direct effect upon blood-sugar content, he could demonstrate a slight improvement in carbohydrate tolerance by giving pure vitamin B. Lactoflavin injected intravenously reduced the blood sugar of diabetic patients by 20 to 30 per cent. Also the intravenous injection of 300 mg. cevitic acid (vitamin C) reduced the blood sugar of normal indi-

viduals, perhaps by inhibiting the insulin antagonist, thyroxine. That vitamin D is involved is proved by the fact that ultraviolet irradiation brings about reduction of the blood and urine sugar in diabetic patients.

Stueck, Flaum and Ralli determined the serum carotene in 13 diabetic patients with clinical evidence of carotenemia and found it to be above normal in all. The average for the group was 0.39 mg per cent. The photoelectric colorimeter was found to be a convenient and accurate instrument in the determination of carotene.

Aszodi and Mosonyi by intravenous administration of vitamins B and C caused an increased secretion of insulin in dogs' blood. In dogs without a pancreas, vitamin C caused only a slight fall of blood sugar, which presumably came from a nervous restrictive mechanism. With dogs with bilateral division of the vagus the insulin secretion was very slight or none at all, this showing a peripheral point of attack of vitamin C. Sigal and King produced in guinea pigs a lowering of carbohydrate tolerance as measured by blood-sugar content when the pigs lived on a diet low in vitamin C. This tolerance returned to normal, however, when the vitamin C was added to the diet.

Gradually, methods for quantitating vitamins are becoming more generally available. Helmer determined vitamins B (antineuritic) and G (lactoflavin) in the human urine by the rat-growth method.

CURE OF DIABETES

Glassberg presents the case histories of 5 patients in whom a diagnosis of "cured diabetes" seemed proper to him. In 4 of the 5 "cured" cases reduction in weight accompanied the increase in tolerance. One gathers that the patients did not show symptoms of diabetes mellitus but that the condition was diagnosed originally by glucose-tolerance curves. The cure was assumed because of the fact that the tolerance curve subsequently became normal. In the discussion Olmsted pointed out that diagnosis by means of tolerance curves, although at the present the only means at our disposal in addition to the evaluation of symptoms, is fraught with danger because of the fact that arbitrary standards must be maintained.

The authors of this review have never encountered a case diagnosed not only on the basis of an abnormal glucose-tolerance curve but also on that of the typical symptoms of polyuria, polydipsia, pruritus and loss of weight and strength which has subsequently failed to show diabetes. The apparent clearing up of the disease which is often seen

in mild diabetic patients who have carefully followed treatment is often shown to be misleading by the intervention of some complication such as an infection with fever, during which time the diabetes once again becomes evident in full force and hyperglycemia and glycosuria reappear. We feel that the following criteria for cure still hold

Diagnosis. The diagnosis of diabetes shall be based upon a glycosuria of 0.5 per cent or more, accompanied by a fasting blood sugar of at least 140 mg per cent or a venous blood sugar after a meal of at least 170 mg per cent.

Duration of Proved Diabetes. The duration of proved diabetes, by repetition of the tests described under diagnosis, shall be recorded in months. By this plan the individual can be classified as a proved diabetic of one or more months' duration. The longer the duration of the proved diabetes, the greater the importance which will be attached to its cure. Chance glycosurias and hyperglycemias resulting from errors in the laboratory, from operative procedures and from temporary infections are thus ruled out. Hyperthyroidism and hyperpituitarism are not excluded, and therefore a statement concerning these conditions should be included in the report of the case.

Test for Recovery. Glycosuria and hyperglycemia shall be absent while the patient is without diabetic medication, both before and an hour after a meal. This meal must contain at least two fifths of the carbohydrate for the day. The carbohydrate for the twenty-four hours shall comprise at least two thirds of the calories necessary to provide 30 calories per kilogram of body weight. Better still, the carbohydrate tolerance shall be unimpaired as judged by a normal glycemic curve following the oral administration of 50 to 100 gm. of glucose to the patient in the postabsorptive state.

Establishment of Recovery. A proved case of one or more months' duration, which conforms to the test for recovery at the beginning and end of an interval of five or more years, shall be considered cured.

ACIDOSIS

The hopes raised by the announcement that succinic acid might prove a valuable therapeutic agent in preventing or treating diabetic acidosis seem to have been false. Dunlop and Arnott found that this substance had no effect in preventing the onset of diabetic coma or in diminishing a chronic diabetic ketonuria. Unfavorable results have also been reported by Lawrence and by Dibold, Frey and Lapp. The latter found no effect exerted upon the acetoneuria in healthy people or in diabetics. Reference should be made also to articles by Koranyi and Szent-Gyorgyi and by Pocza.

Deuel, Murray and Hallman conclude that succinic acid is ineffective in preventing the ketonuria in fasting rats previously fed a high-fat diet, even when this acid is administered in amounts far in excess of the quantity of glucose required to produce a marked decrease in the excretion of the ketone bodies.

A discussion of ketonemia vomiting in diabetic

and nondiabetic children by Hungerland brings out two opposing points of view, one favoring and the other disapproving the use of insulin in non-diabetic children with ketonuria due to vomiting. The important point is not to miss the diagnosis of diabetes. While carbohydrate feeding may be sufficient treatment in nondiabetics, it is not enough for the diabetic child in coma.

ENDOCRINOLOGY

The demonstration by Young that experimental diabetes can be produced in a dog by injections of large amounts of an extract obtained from the anterior lobe of the pituitary again centers attention upon the pituitary gland in relation to diabetes. Working at the National Institute for Medical Research at London, Young administered daily twenty-six and twenty-one days, respectively, anterior pituitary extract to 2 dogs by the intraperitoneal route, as a result, they became diabetic and remained so after the injections were stopped, without showing any signs of recovery. A third animal similarly treated became only temporarily diabetic. The permanent diabetes thus produced differed from that of depancreatized dogs in that the pituitary treated dogs appeared to be able to survive without insulin, retaining vigor, and in 1 case there was no loss of weight. The extract was prepared from fresh ox anterior pituitary glands, and all the procedures for extraction and preparation were carried out at temperatures approaching 6°C. In 1 dog, the extract from 490 gm of ox pituitary was used.

In 1 dog of his series, four weeks after the cessation of injections, the sugar excretion was 264 gm (24 gm per kilogram) a day. The fasting blood sugar at the end of forty-eight hours was 256 mg per cent. This dog became diabetic in September, 1936, and insulin was not given until March, 1937. Death occurred in coma on the sixth day after insulin was discontinued, and nearly ten months after the pituitary injections were discontinued. At autopsy, the liver was large and fatty, weighing 1030 gm., and the pancreas weighed 52 gm.

Young's experiments are epoch making. They mark the first successful production of diabetes by methods other than pancreatectomy, and furthermore, the first instance in which a chronic metabolic disease has been produced experimentally by the injection of material obtained from normal glands.

An alkaline extract of the anterior lobe of the pituitary has a marked diabetogenic action in both normal and diabetic subjects, according to Lassen and Hansen. They obtained an increased ammonia elimination due to the ketogenic effect. The height

of the blood-sugar curve after a meal was increased only if the carbohydrate was limited, but the extent of the curve was increased.

Lämmlé describes a case of acromegaly due to an eosinophilic adenoma in which the metabolism was 50 per cent above normal and the diabetes scarcely controllable with diet and insulin. Removal of the tumor did not help, but later thyroidectomy, although no signs of Basedow's disease was present, brought about disappearance of insulin resistance, glycosuria and hyperglycemia. It would seem in this case, therefore, that the insulin resistance was due chiefly to the increased metabolism which was mediated through the thyroid gland.

The question often raised as to the possible benefits in diabetes of giving x-ray treatment to the pituitary is apparently answered rather completely by the studies of Pijoan and Zollinger. They studied the carbohydrate metabolism of patients undergoing massive radiation of the pituitary regions (because of the menopausal syndrome) before and after the radiations. Ten patients whose ages varied from twenty-nine to fifty received a total of 1400 to 1600 r skin doses over a period of fourteen days. Their blood-sugar curves were obtained after the oral administration of 1 gm of dextrose per kilogram of body weight, in a second series of experiments the blood-sugar values were determined after the intravenous administration of 0.35 units of insulin per kilogram of body weight. Neither set of experiments showed any essential difference between the curves obtained before the radiation and after it. In 1 case the changes in the respiratory quotient were observed after dextrose and after insulin and again perfectly comparable curves were obtained. Pijoan and Zollinger conclude that such radiation of the pituitary gland caused no change whatever in carbohydrate metabolism. In commenting upon these fundamental observations, one would say, first, that a priori no very marked change should be expected in the function of a gland treated with clinical doses of x-ray in which the cells are of the normally differentiated type. It is really only in cells of new growths in which the differentiation of cell structure has not reached its final stage that irradiation may be expected to disturb the function. However, even in some such tumors of the pituitary the evidence that radiation produces any very great change is somewhat contradictory.

Carey, Arey and Norris report a case of myxedema and diabetes with autopsy. The carbohydrate tolerance was reduced when the basal metabolism was increased by thyroid treatment. This fact is to be considered in connection with the case of Escamilla, Lisser and Shepardson in whose

viduals, perhaps by inhibiting the insulin antagonist, thyroxine. That vitamin D is involved is proved by the fact that ultraviolet irradiation brings about reduction of the blood and urine sugar in diabetic patients

Stueck, Flaum and Ralli determined the serum carotene in 13 diabetic patients with clinical evidence of carotenemia and found it to be above normal in all. The average for the group was 0.39 mg per cent. The photoelectric colorimeter was found to be a convenient and accurate instrument in the determination of carotene.

Aszodi and Mosonyi by intravenous administration of vitamins B and C caused an increased secretion of insulin in dogs' blood. In dogs without a pancreas, vitamin C caused only a slight fall of blood sugar, which presumably came from a nervous restrictive mechanism. With dogs with bilateral division of the vagus the insulin secretion was very slight or none at all, this showing a peripheral point of attack of vitamin C. Sigal and King produced in guinea pigs a lowering of carbohydrate tolerance as measured by blood-sugar content when the pigs lived on a diet low in vitamin C. This tolerance returned to normal, however, when the vitamin C was added to the diet.

Gradually, methods for quantitating vitamins are becoming more generally available. Helmer determined vitamins B (antineuritic) and G (lactoflavin) in the human urine by the rat-growth method.

CURE OF DIABETES

Glassberg presents the case histories of 5 patients in whom a diagnosis of "cured diabetes" seemed proper to him. In 4 of the 5 "cured" cases reduction in weight accompanied the increase in tolerance. One gathers that the patients did not show symptoms of diabetes mellitus but that the condition was diagnosed originally by glucose-tolerance curves. The cure was assumed because of the fact that the tolerance curve subsequently became normal. In the discussion Olmsted pointed out that diagnosis by means of tolerance curves, although at the present the only means at our disposal in addition to the evaluation of symptoms, is fraught with danger because of the fact that arbitrary standards must be maintained.

The authors of this review have never encountered a case diagnosed not only on the basis of an abnormal glucose-tolerance curve but also on that of the typical symptoms of polyuria, polydipsia, pruritus and loss of weight and strength which has subsequently failed to show diabetes. The apparent clearing up of the disease which is often seen

in mild diabetic patients who have carefully followed treatment is often shown to be misleading by the intervention of some complication such as an infection with fever, during which time the diabetes once again becomes evident in full force and hyperglycemia and glycosuria reappear. We feel that the following criteria for cure still hold

Diagnosis The diagnosis of diabetes shall be based upon a glycosuria of 0.5 per cent or more, accompanied by a fasting blood sugar of at least 140 mg per cent or a venous blood sugar after a meal of at least 170 mg per cent.

Duration of Proved Diabetes The duration of proved diabetes, by repetition of the tests described under diagnosis, shall be recorded in months. By this plan the individual can be classified as a proved diabetic of one or more months duration. The longer the duration of the proved diabetes, the greater the importance which will be attached to its cure. Chance glycosurias and hyperglycemias resulting from errors in the laboratory, from operative procedures and from temporary infections are thus ruled out. Hyperthyroidism and hyperpituitarism are not excluded, and therefore a statement concerning these conditions should be included in the report of the case.

Test for Recovery Glycosuria and hyperglycemia shall be absent while the patient is without diabetic medication, both before and an hour after a meal. This meal must contain at least two fifths of the carbohydrate for the day. The carbohydrate for the twenty-four hours shall comprise at least two thirds of the calories necessary to provide 30 calories per kilogram of body weight. Better still, the carbohydrate tolerance shall be unimpaired as judged by a normal glycemic curve following the oral administration of 50 to 100 gm. of glucose to the patient in the postabsorptive state.

Establishment of Recovery A proved case of one or more months' duration, which conforms to the test for recovery at the beginning and end of an interval of five or more years, shall be considered cured.

ACIDOSIS

The hopes raised by the announcement that succinic acid might prove a valuable therapeutic agent in preventing or treating diabetic acidosis seem to have been false. Dunlop and Arnott found that this substance had no effect in preventing the onset of diabetic coma or in diminishing a chronic diabetic ketonuria. Unfavorable results have also been reported by Lawrence and by Dibold, Frey and Lapp. The latter found no effect exerted upon the acetoneuria in healthy people or in diabetics. Reference should be made also to articles by Koranyi and Szent-Gyorgyi and by Poczka.

Deuel, Murray and Hallman conclude that succinic acid is ineffective in preventing the ketonuria in fasting rats previously fed a high-fat diet, even when this acid is administered in amounts far in excess of the quantity of glucose required to produce a marked decrease in the excretion of the ketone bodies.

A discussion of ketonemia vomiting in diabetic

and nondiabetic children by Hungerland brings out two opposing points of view, one favoring and the other disapproving the use of insulin in nondiabetic children with ketonuria due to vomiting. The important point is not to miss the diagnosis of diabetes. While carbohydrate feeding may be sufficient treatment in nondiabetics, it is not enough for the diabetic child in coma.

ENDOCRINOLOGY

The demonstration by Young that experimental diabetes can be produced in a dog by injections of large amounts of an extract obtained from the anterior lobe of the pituitary again centers attention upon the pituitary gland in relation to diabetes. Working at the National Institute for Medical Research at London, Young administered daily for twenty-six and twenty-one days, respectively, anterior pituitary extract to 2 dogs by the intraperitoneal route, as a result, they became diabetic and remained so after the injections were stopped, without showing any signs of recovery. A third animal similarly treated became only temporarily diabetic. The permanent diabetes thus produced differed from that of depancreatized dogs in that the pituitary treated dogs appeared to be able to survive without insulin, retaining vigor, and in 1 case there was no loss of weight. The extract was prepared from fresh ox anterior pituitary glands, and all the procedures for extraction and preparation were carried out at temperatures approaching 0°C. In 1 dog, the extract from 490 gm of ox pituitary was used.

In 1 dog of his series, four weeks after the cessation of injections, the sugar excretion was 264 gm (24 gm per kilogram) a day. The fasting blood sugar at the end of forty-eight hours was 256 mg per cent. This dog became diabetic in September, 1936, and insulin was not given until March, 1937. Death occurred in coma on the sixth day after insulin was discontinued, and nearly ten months after the pituitary injections were discontinued. At autopsy, the liver was large and fatty, weighing 1030 gm., and the pancreas weighed 52 gm.

Young's experiments are epoch making. They mark the first successful production of diabetes by methods other than pancreatectomy, and furthermore, the first instance in which a chronic metabolic disease has been produced experimentally by the injection of material obtained from normal glands.

An alkaline extract of the anterior lobe of the pituitary has a marked diabetogenic action in both normal and diabetic subjects, according to Lassen and Hansen. They obtained an increased ammonia elimination due to the ketogenic effect. The height

of the blood sugar curve after a meal was increased only if the carbohydrate was limited, but the extent of the curve was increased.

Lammli describes a case of acromegaly due to an eosinophilic adenoma in which the metabolism was 50 per cent above normal and the diabetes scarcely controllable with diet and insulin. Removal of the tumor did not help, but later thyroidectomy, although no signs of Basedow's disease was present, brought about disappearance of insulin resistance, glycosuria and hyperglycemia. It would seem in this case, therefore, that the insulin resistance was due chiefly to the increased metabolism, which was mediated through the thyroid gland.

The question often raised as to the possible benefits in diabetes of giving x-ray treatment to the pituitary is apparently answered rather completely by the studies of Pijoan and Zollinger. They studied the carbohydrate metabolism of patients undergoing massive radiation of the pituitary regions (because of the menopausal syndrome) before and after the radiations. Ten patients whose ages varied from twenty-nine to fifty received a total of 1400 to 1600 r skin doses over a period of fourteen days. Their blood-sugar curves were obtained after the oral administration of 1 gm of dextrose per kilogram of body weight, in a second series of experiments the blood-sugar values were determined after the intravenous administration of 0.35 units of insulin per kilogram of body weight. Neither set of experiments showed any essential difference between the curves obtained before the radiation and after it. In 1 case the changes in the respiratory quotient were observed after dextrose and after insulin and again perfectly comparable curves were obtained. Pijoan and Zollinger conclude that such radiation of the pituitary gland caused no change whatever in carbohydrate metabolism. In commenting upon these fundamental observations, one would say, first, that a priori no very marked change should be expected in the function of a gland treated with clinical doses of x-ray in which the cells are of the normally differentiated type. It is really only in cells of new growths in which the differentiation of cell structure has not reached its final stage that irradiation may be expected to disturb the function. However, even in some such tumors of the pituitary the evidence that radiation produces any very great change is somewhat contradictory.

Carev, Arey and Norris report a case of myxedema and diabetes with autopsy. The carbohydrate tolerance was reduced when the basal metabolism was increased by thyroid treatment. This fact is to be considered in connection with the case of Escamilla, Lisser and Shepardson in whose

patient, a non-diabetic, the sugar-tolerance curve was greatly elevated by the giving of thyroid extract. When the metabolism once again fell to —22 per cent the blood-sugar curve went back to normal. Labbé holds that the frequency of exophthalmic goiter in diabetes is too great to be a mere coincidence. He feels that many cases are to be regarded as a true thyroid diabetes dependent upon a disturbance in thyroid glycoregulation, and differing from the ordinary pancreatic diabetes. However, in our experience among diabetic patients in whom the diagnosis of diabetes was clearly dependent upon hyperglycemia, glycosuria and a characteristic history, the fundamental severity of the diabetes has not been affected by operation upon the thyroid. Temporary severity, even acidosis, is helped by the reduction in metabolism following operation. Furthermore, at autopsy those cases have shown changes in the pancreas similar to those found in cases of diabetes without thyroid complications.

Meythaler and Mann found in both hyperthyroidism and myxedema a marked sensitiveness to insulin. (The patients studied were nondiabetics.) The authors explain this apparent contradictory finding on the basis of an altered functional status of the sympathicoadrenal system. Although hyperthyroidism is associated with an increased, and hypothyroidism with a decreased, sympathetic tonus, the response to insulin is the same, since in the former condition there is glycogen lack (due to hyperfunctioning of the sympathicoadrenal system), and in the latter normal glycogen content of the liver (due to hypofunctioning of the sympathicoadrenal system). An overproduction of adrenine in the presence of glycogen lack is without effect, while on the other hand rich glycogen stores, as in myxedema, represent a useless depot since the mobilizing agent, adrenine, is not present in sufficient amounts.

Fazekas, Himwich and Martin ligated the lumbo-adrenal veins of 8 cats distally and proximally to the adrenal glands, and at the same operation removed the entire pancreas. The animals were maintained without insulin or cortin. The survival period of the animals was definitely prolonged by the ligation, and 1 animal lived ninety-eight days. These experiments should be considered in relation to Long's demonstration of the ameliorating effect upon diabetes in depancreatized cats produced by adrenalectomy. Suggestions of the clinical effects of the adrenal gland are made by Langfeldt, whose patient, a man with melancholia, had moderate sensitiveness to insulin following an opium cure. He developed coma with 72 units of insulin. Langfeldt raises the question whether opium depresses the production of adrenine.

PHYSIOLOGY

The significance of the variations in the sugar content of other tissues of the body besides the blood is receiving study. An example is the study of the sugar in the skin previously reported by Urbach. Greif states that the sugar concentration of the marrow of the sternum is regulated within certain bounds independently of the blood sugar, and that its percentage represents the sugar formed locally in the tissues. The fasting values in 21 healthy subjects were between 39 and 155 mg per cent. At times (12 cases) the sternal-marrow sugar was very different from the blood sugar. Sometimes it was lower and twice it was higher than blood sugar, a fact which suggested autochthonous regulation. To various tolerance tests with glucose, adrenalin and insulin there were similar variations in sternal-marrow sugar as with blood sugar, but of quite independent character, at times being later or earlier than with blood sugar, and at times showing divergencies in the curves.

LIVER

The early demonstration of Minkowski that the liver exerts the power of transforming levulose into glycogen is referred to by Paisseau, Ferriar and Mangeot, who report another case of levulose in a child of five. They state that there is no experimental evidence that insulin improves the metabolism of levulose. The reduction in the size of the liver in diabetic children as brought about by insulin in controlling the diabetes is more important than other measures. However, Eder and Gray successfully treated 5 such children with iron. They felt that the iron treatment was the main reason for the reduction in the size of the liver. Rathery and Froment, in reporting the case of a woman with gallstones, discuss the possible causation of diabetes by inflammation of the head of the pancreas along with gallstones. However, in their case little evidence of inflammatory effect either in the liver or the pancreas was found.

Terbruggen in diabetic patients under fifty noticed no disease of the gall bladder. He holds also that the concurrence of diabetes with gallstones is not so frequent as to suggest a causal connection between the two.

Bridge utilized the respiratory quotient in a study of the glycogen reserve of the liver and the muscles in rabbits. At present there is no known way of estimating the glycogen reserve of either animals or human beings. Without doubt, in the future some method of determining the glycogen reserve will be found, and it will have an important place in the clinical study and treatment of patients. Bridge's rabbits in general showed a high fasting respiratory quotient, correlated with

rich glycogen reserves in the liver. On the other hand, the content of the muscle glycogen as determined immediately after death was not so clearly correlated with the respiratory quotient. These results were somewhat surprising in view of the fact that muscles constitute about 45 per cent of the total weight of a rabbit, and should have a correspondingly predominant influence upon the respiratory quotient. On the other hand, the liver which represents only 4 to 10 per cent of the total weight, could hardly be expected to dominate the combustion in the body as it seemed to do in these rabbits.

The influence of other endocrine glands upon glycogen metabolism in the liver is receiving increasing attention.

In a brief communication Young reports that the livers and possibly the muscles of fasting rabbits injected with extracts of fresh ox (anterior lobe) pituitaries contained more glycogen than similar tissues of control animals. He suggests as an explanation that in the injected fasting animals glycogenesis proceeded at an increased rate.

Raab and Strauber obtained blood-sugar curves in 12 normal individuals, in 12 diabetic patients and in 10 patients with catarrhal jaundice, following each of two consecutive injections of 0.5 mg of adrenalin at intervals of two and a quarter hours. Furthermore, tests were carried out on 5 normal individuals and 5 with catarrhal jaundice, after each of two administrations of 50 gm of sugar at intervals of one and a half hours.

In all the normal individuals, following the giving of adrenalin and sugar, the second curve was lower than the first. In the diabetic patients, the effect of the first adrenalin injection was greater. Usually the peak of the second adrenalin curve lay higher than the first, but the absolute size of the second curve was on the average lower than the first, as in the normal cases.

In the cases of catarrhal jaundice the fasting blood sugar was normal. The effect of the first injection of adrenalin was somewhat decreased, but that following the first administration of sugar was increased. The second adrenalin peak lay, in contrast to the normal, without exception higher than the first, the absolute size of the second adrenalin effect remained on the average a little less than that of the first, as in the normal cases, in a few cases it was even greater. The peak of the second sugar-tolerance curve lay, in contrast to the normal, much higher than the first, the absolute size being on the average smaller than the first and smaller than in the normal cases.

The results in the diabetic patients were attributed by these authors on the one hand to lack of insulin and on the other to a disturbance of

glycogenesis. In explaining the results obtained in catarrhal jaundice it was assumed that there was a diminished capability of the liver cells for taking up sugar, and in addition an intact and even increased intrahepatic metabolism of sugar taken up and a mild insufficiency of the pancreatic island apparatus. An increased sensitiveness to adrenalin does not exist in catarrhal jaundice, either in connection with blood sugar or with blood pressure.

The peculiar tendency for fat to be moved from other tissues and to be deposited in the liver has been a fundamental characteristic of diabetes. Kaplan and Chaikoff, working with completely depancreatized dogs, compared the fatty acid content of a mixed sample of entire liver with that in its lobes and in sections of them. The values obtained by these three types of sampling showed that fatty acids were not evenly deposited in the liver as fat accumulates. Because of this these authors point out that it is not fair to employ lobes and sections of lobes in estimating the fatty acid content of the whole liver.

Kaplan and Chaikoff found that it required a period of at least sixteen weeks to ensure a consistent finding of fatty acids in excess of 14 per cent in the livers of completely depancreatized dogs. Furthermore, if completely depancreatized dogs survive long enough, spontaneous regression of the fatty livers may occur despite the absence of raw pancreas in the diet during the entire period. The authors found that the ingestion of raw pancreas prevented the infiltration of fat in the livers of depancreatized dogs. They report that this factor is heat-stable in contradistinction to the heat-labile factor in the pancreas, which, when it is ingested by completely depancreatized dogs being maintained with insulin, produces an elevation in blood lipids above the normal.

Kaplan and Chaikoff maintain that although choline when given to completely depancreatized dogs influences deposition of liver fat, its curative action is slow, and daily feeding for a long time is required to produce measurable effects on livers in which large amounts of fat have accumulated. Furthermore, the authors find that choline does not raise the blood lipids in depancreatized dogs above the normal level, and in conclusion say that the pancreatic blood-lipid factor is therefore not choline.

In this connection, it is relevant to cite the views of Best, who does not maintain that the sole potent factor in raw pancreas is choline. Indeed, he recognizes four possible influences: choline as such, the protein of raw pancreas which in itself has a lipotropic action, pancreatic enzymes which by

their action may release more protein and choline, and the possible presence of betaine and other substances in raw pancreas which in addition to choline may possess lipotropic activity

CARBOHYDRATE METABOLISM

Meythaler found that the regulation of carbohydrate metabolism during athletic exercise depends above all upon training. The more in training an individual is, just so much more efficiently does he store glycogen in his depots. Since we know that trained animals, even after activity which is completely exhausting, still possess a considerable amount of glycogen in the liver, it is improbable that pure glycogen deficiency is responsible for the different course of carbohydrate metabolism in sport. The factor of glycogen lack is at most to be considered in extreme activity as in marathon races. Rather, Meythaler believes that his results have shown above all that the different course of carbohydrate metabolism in sport is related to the different demands of the sympathicoadrenal system. Training implies an adaptation in the periphery to increased capability of action, which in turn depends presumably upon an increased activity of the vegetative nervous system. In the last analysis, the efficiency of the sympathicoadrenal system governs the degree of capability in a highly trained condition.

Sheldon, Johnston and Newburgh, using a respiration chamber, found that 3 normal, male, fasting subjects oxidized increasing amounts of glucose in response to increasing quantities of carbohydrate in the preparatory diet (used for three or more days prior to the day of the test). Furthermore, the subjects oxidized more glucose during the four hours of the test in response to increasing amounts of glucose ingested at the beginning of the test, even though the preparatory diet had been the same. The effect was additive when both sources of carbohydrate were increased simultaneously. The response of 3 male diabetic patients was qualitatively similar but quantitatively smaller. The ability of the diabetics to oxidize glucose was directly related to the severity of the disease. Carbohydrate, in excess of the ability of these diabetics to oxidize it, was of no benefit.

The interpretation of glucose-tolerance curves is often puzzling, especially in the presence of some complication. Peskin describes a small group of patients with symptoms in many respects similar to those of peptic ulcer, but in whom upon roentgenological examination no ulcer could be demonstrated. The author outlines the various criteria which distinguish this condition from true peptic ulcer, chief among these being the extraordinary

response to the giving of 50 or 100 gm of glucose by mouth. Instead of the usual blood-sugar curve obtained in the nondiabetic individual, the curve takes on a definitely negative characteristic, the blood sugar, instead of rising, descends to a low level (in the published curves, to as low as 50 mg per cent), and then gradually ascends, although never attaining normal. These patients possess a high metabolic rate and show the symptoms of tachycardia, — excessive sweating, tremor, nervousness and eye symptoms, — suggesting a thyroid abnormality. Successful treatment consisted in placing the patient on a diet poor in carbohydrate and protein and high in fat.

Deren studied the dextrose tolerance of 50 subjects over fifty-five years of age without complications. One half of the group were studied with the ordinary 100 gm dextrose-tolerance test, and in 16 a high prolonged curve was observed. In only 4 were normal blood-sugar curves observed. With the one-hour, two-dose method of Exton and Rose there were 21 diabetic and 4 normal types of sugar curves. This seems an extraordinarily high percentage and should encourage further study in this field.

Bergman and Drury found that the rate of utilization of glucose by eviscerated rabbits was affected by feeding and fasting prior to operation. The tissues of the fed animals utilized glucose at a rate double that of the fasted rabbits. The authors present evidence to show that this increase cannot be due to insulin but is rather due to some other influence, possibly that of the pituitary.

METHODS

Rhodehamel, Rose and Chen report the development of a simple and rapid method for determining sugar in the urine, and describe in some detail the apparatus needed and the method followed. The method is based upon that previously described by Sheftel, which depends upon the fact that the cuprous oxide formed by reduction takes on a yellow instead of a red color in the presence of a sufficient amount of creatinine and a hydrophilic colloid such as acacia. The yellow cuprous oxide forms different shades of color from green to yellow, with an excess of blue cupric ions, depending upon the amount of sugar present. A colored chart is used, the colors corresponding to various concentrations of glucose.

Greeley describes a method for complete pancreatectomy in the rabbit. His method calls for a three-stage procedure with three to four weeks between operations. Blood-sugar values in animals so depancreatized (fed without insulin) remained at a level of 400 to 500 mg per cent.

NERVOUS SYSTEM AND DIABETES

The varied manifestations and clinical relation of hypoglycemia concern the psychiatrist and surgeon as well as the internist. The present attempts to treat schizophrenia and other psychoses by means of hypoglycemia induced by large doses of insulin afford the opportunity to witness many interesting neurologic manifestations, which according to Golden have not been described as arising as complications of diabetic treatment or symptoms of pancreatic adenoma. These may be classified as follows:

Prolonged manifestations, occurring for a longer period during the four to five hours of treatment

Quick jerking movements of arms, legs and body and restless tossing of the head

Prolonged sucking movements of lips

Episodes initiated by flushing of face, dilation of pupils and labored breath, with rigid extension of lower extremities, bilateral adduction and extreme internal rotation of rigidly held arms, clinically suggesting decerebrate rigidity

Partial manifestation of the above, the legs remain normal.

Irregular, thrashing, apparently purposeless movements of the arms and legs, suggesting true defense reflexes

Deep reflexes difficult to evaluate. Occasional Babinski and disappearance of corneal reflex

Slow trombone like movements and irregular jerks of tongue after other clonic movements

Extremities showing frozen athetoid movements

Transitory hemiplegias

All the above were most often bilateral but were at times unilateral

Sudden manifestations, usually toward the end of treatment.

Frequent convulsive seizures

Dramatic complications, suggesting that the whole central nervous system is thrown into a frenzy of disorganized activity

If the patient did not react in forty-five minutes, even when intravenous glucose had been given, trouble was to be expected. The pupils were small, slowly dilated and were associated with marked flushing of the face. These followed convulsions, labored breathing and complete exhaustion. There were alternate periods of activity and relaxation, at times continued for one or two hours, the attack diminishing in severity and duration at each occurrence.

The tremendous importance of insulin hypoglycemia treatment in relation to schizophrenia is brought out by Cameron and Hoskins, who point out that because of the chronicity of this disorder, schizophrenic patients occupy one fifth of all the hospital beds in the United States. The sponta-

neous remission rate is from 20 to 40 per cent, and this makes it difficult to interpret the results of any treatment.

Lemere treated 17 chronic cases of dementia praecox and obtained a remission in 23 per cent. He believes that the effect of insulin shock is nonspecific, and that any agent that produces a convulsant action on the cerebral cortex has the same result.

Himwich and Fazekas studied the effect of hypoglycemia upon the brain metabolism. The brain seems to be the only organ which acquires its energy exclusively from the oxidation of carbohydrate. Its respiratory quotient *in situ* is unity. Furthermore, it has but little store of carbohydrate. Even in diabetes the respiratory quotient of the brain remains unchanged, according to the experimental work of these men. They state that there is no evidence that fat enters into the respiratory metabolism of the brain, because acetone substances are neither poured into the blood stream during diabetes nor absorbed for oxidation from ketonemic blood traversing the brain. They studied the changes in the brain of 14 dogs anesthetized with Amytal. During hypoglycemia the utilization of glucose on the average was 12.5 per cent and that of oxygen 7.99 per cent. When the blood-sugar values were as low as 22 mg per cent, the utilization of glucose was less than of oxygen, showing that the small store of carbohydrate in the brain must have been utilized during this period of intense hypoglycemia. They considered it probable that the central nervous system ceased to function only when no further carbohydrate, either in the blood or in the brain, was available.

According to Page, whose new monograph reviews the entire present knowledge of the chemistry of the brain, brain tissue does not lose the power of converting glucose to lactic acid in diabetes, but little of the lactic acid produced is formed from glycogen, most of it being formed directly from blood sugar.

Electroencephalographic records during thirty-five insulin treatments of 6 schizophrenic patients are reported by Hoagland and his associates. After large doses of insulin the brain waves show a progressive decline of the alpha wave (Berger rhythm) of some 40 per cent, which parallels the declining blood-sugar curve. Sugar injections during the hypoglycemia restore the frequency. The present view is that alpha frequencies are directly proportional to the rate of carbohydrate metabolism of the cortical cells producing the rhythm.

Resistance to insulin was early noted by Sakel in certain cases of schizophrenia when insulin was given for hypoglycemia treatment. Varela-Fuentes and Rawak described 1 patient who received 160

units and another who received 350 units intravenously without much effect. Intravenously they gave as much as 360 units. They considered the possibility that in certain cases of this disease there exists on the part of the adrenal medulla an extraordinary capacity for reacting which permits an outpouring of adrenine which counteracts the insulin.

Quigley studied the effects of atropine or novatropine following the production of hypoglycemia with insulin in 6 normal medical students. He found that the hypoglycemic symptoms were effectively counteracted by moderate doses. However, after twenty-five or more minutes, in 50 per cent of the experiments, pronounced mental disturbances, chiefly amnesia and speech disturbances of varying intensity, developed, presumably because of a synergistic action of insulin with the other drugs used. The author warns against the use of atropine preparations in a patient with hypoglycemia unless due regard is given to the mechanism by which the hypoglycemia is produced.

Scott estimated the blood sugar following encephalography on 75 patients because of the reported observation that following the taking of encephalograms the blood sugar rises. The highest values obtained in his series averaged 152 mg. The maximum value was 234 mg. and the lowest 100 mg. The high values in most cases occurred in epilepsy and the low values were in cases of tumor of the brain. The author directs attention to a report by Reese in a case in which diabetic coma developed after encephalography, and the patient died.

Kraus and Chaney describe a man of thirty-six who was given antitetanic serum and developed pain, nausea, vomiting and finally atrophy of the muscles about the shoulder. Other patients in their series showed paralysis or disturbance of sensation, particularly of the hands or arms, but all recovered.

These symptoms of serum disease of the nervous system may possibly explain an unusual case in our experience. In Case 7150 the patient developed symptoms some few weeks after he began to use protamine insulin, these consisted of transitory weakness of one arm, then a weakness of the right foot with various reflex changes which were quite characteristic of multiple sclerosis. At the end of eighteen months the symptoms are now somewhat improved. Whether time will prove that this is a case of true multiple sclerosis rather than serum disease of the nervous system, we cannot tell.

COMPLICATIONS

Pregnancy Since the introduction of insulin the number of diabetics who become pregnant has increased largely owing to the prolongation of the

lives of juvenile diabetics and the increased fertility of adult diabetics. Hurwitz and Irving report that, since 1916, 51 diabetics were delivered at the Boston Lying-in Hospital without death from diabetes. They discuss the fetal mortality given by previous writers, varying in the region of 45 per cent. The mortality at this hospital between 1916 and 1932 was 43 per cent, if, however, it were corrected to consider only those infants alive in utero at the first examination, the rate would be only 25 per cent. In 1932, 18 diabetic pregnancies had a gross fetal mortality of 17 per cent, though again, if correction is made, the rate is only 11 per cent. The high rate is due to acidosis, excessive size of the fetus and increased frequency of fetal anomaly. Hurwitz and Irving conclude that under proper management the diabetic mother may be expected to go through pregnancy and labor successfully. Cesarean section is reserved for cases in which the infants exceed normal weight or there are obstetric indications. They hold that insufficient stress is laid upon the peculiar types of toxemias seen in diabetic mothers, and particularly on the danger of pregnancy to young diabetic women whose diabetes began in childhood and is of long duration.

Tuberculosis Our further experience with tuberculosis and diabetes is giving us a more hopeful attitude. Thus, in the follow-up of our acidosis cases at the Deaconess Hospital, a much lower rate of development of pulmonary tuberculosis is being encountered than formerly. The much improved prognosis in acute cases is well illustrated by the case reported by Shepardson and Noble, the patient was a registered nurse of thirty-four, with diabetes of five years' duration, who was taking insulin. Four years after the onset of diabetes she had diabetic coma, which required 175 units of insulin in twenty-four hours. Her acute illness with fever and night sweats and cough did not begin until a year after this coma, and she then had tuberculous pneumonia, the sputum showing many tubercle bacilli. There were two cavities. Artificial pneumothorax was used, with excellent results. During the next two years she gradually improved and since July, 1935, she had been carrying on her duties as a nurse.

Bertram, discussing his 80 cases of tuberculosis in diabetics again denies that he has ever had hemorrhages of the lung as a result of insulin injections. He believes that Kaiser's cases were given diets too low in carbohydrate, and that this may have been the cause of the bleeding, although he admits that possibly adrenalin could have been responsible. He urges high-carbohydrate diets.

One must still recognize the danger of tuber-

culosis in diabetic patients, particularly in the young. Dunlop emphasized this danger especially in children who have had coma. Interesting experiments on the development of tuberculosis were carried out by Schedtler on animals whose thyroid glands had been removed or which had been given thyroxin. The fact that tuberculosis seems to progress rapidly in the presence of myxedema is often commented upon. This is of interest in relation to the possibility that fat metabolism and particularly the cholesterol in the blood are factors in resistance to tuberculosis. This relation is clearly shown in diabetic patients who have had acidosis and lipemia.

Vascular Disease Cardiovascular disease, together with peripheral vascular disease, continues to be a major problem in the treatment of diabetes. Radnai and Weisz studied 400 cases and made electrocardiographic examinations of 260 of them. Forty per cent of the latter cases showed changes. Cardiac decompensation was discovered in 20 per cent and angina pectoris in 10 per cent. The frequency of cardiac decompensation of the congestive type is rather striking in this series. In general, at the Deaconess Hospital we have found that congestive failure occurs rather less frequently than in a general cardiac clinic.

Edelen emphasizes what we have so long practiced at the Deaconess Hospital, namely the avoidance of heat in the treatment of impaired circulation of the feet. The danger of increasing the tissue metabolism above the level where the blood supply is capable of providing sufficient circulation, and thereby hastening gangrene, is a real one. By all means continually repeat the warning to the patient: Do not have a hot-water bottle, hot stones, or any source of heat in bed with you.

Scupham and de Takats give an excellent review of the recent literature on peripheral vascular disease. De Takats comments especially on the methods of arteriectomy recommended by Leriche for cases with completely obliterated arteries. Leriche has emphasized that an obliterated artery ceases to function as a carrier of blood and becomes a diseased plexus of the sympathetic nerve fibers which maintain vascular spasm, he therefore advocates removing this section of the artery. De Takats, while granting that this is an important principle and deserves consideration, points out that the results of arteriectomy are not encouraging.

Dermatology Sugg and Stetson describe a young man of twenty-seven, exceptionally obese, who developed lesions of xanthoma tuberosum on the elbows and knees at points where his occupation as a tile setter had traumatized the skin. His dia-

betes was extremely mild, the blood cholesterol was only 170 mg. Two nodules were removed for biopsy, they showed foamy cells, and a diagnosis of fibroxanthoma was made.

Surgery Atnan and Fenz studied the blood sugar before, during and after various types of anesthesia in nondiabetic and diabetic patients. They found that with Evipan given intravenously the blood sugar rose only slightly, even in the diabetic patient with spinal anesthesia the increase was much less than with ether anesthesia but lasted longer. The authors conclude, however, that spinal anesthesia is not contraindicated in diabetes mellitus.

Continued improvement in the results of surgical treatment are reported where good medical and surgical teamwork is brought about. Williams and O'Kane report a five-year study of 496 cases. The mortality in cases with lower-extremity lesions, operated and unoperated, fell from 48 to 19 per cent.

Because of the distribution of surgical diabetics in the older age groups with impaired circulation, we have given further attention to the problem of pulmonary embolism following Barnes's excellent review from the Mayo Clinic. Our regime has already included, among other things, the rubbing of backs and turning of patients every two hours day and night and the use of the Balkan frame and other measures for exercising the upper extremities of all patients constantly in bed. We now insist that all elderly patients in bed flex and extend the legs and exercise the feet once an hour, and take several deep breaths or cough once an hour in order to promote venous return from the extremities. Finally, we have redoubled our efforts in this group to prevent abdominal distention as a definite factor in causing venous stasis in the pelvis and lower extremities.

Trauma During 1937 appeared the volume *Trauma and Disease* edited by Brahdy and Kahn (Lea & Febiger), Chapter XV is devoted to "Trauma and Diabetes." In this chapter Joslin, Root and Marble have assembled the literature, mostly German, upon the subject and have added their own material. The forty-five page article is too long for review, but so few publications upon the subject have appeared in English that attention is called to it. An abstract of the article appears in Joslin's *Treatment of Diabetes* (Lea & Febiger, 1937).

In Germany, Umber has written extensively upon trauma and diabetes. In an address in Berlin he restated his earlier view: "Traumatic glycosurias occur, but there is no traumatic diabetes." In legal

studies, the most frequent errors come from the use of material which was published before the discovery of insulin. In those early days it was difficult to distinguish between glycosuria and diabetes. The classical type of the former is the glycosuria resulting from the Claude Bernard puncture.

CASE 24221

PRESENTATION OF CASE

A twenty-two-year-old, white, American law student entered the hospital with the complaints of stiffness of the legs and malaise.

Three weeks before entry he began to have vague pains in the joints, bones and muscles, particularly in the lower legs, which were somewhat stiff. He also noticed loss of energy, especially during the week before entry. During the two days before entry his ankles and elbows were painful on motion, and there was swelling of his ankles, his shins became sore, and a painful, tender red spot appeared on the index finger of his right hand. He did not feel feverish but was abnormally sensitive to cold. He had had a cold a month before entry, but that had cleared up, and he had had no further upper respiratory infection. There had been no nosebleeds, frequency or nocturia.

Thirteen years before entry, following a sore throat, he had had rheumatic fever, which was acute for one week and subacute for six months. He was kept in bed during that time. Three years later a definite diagnosis of aortic insufficiency was made, although at that time his heart was not enlarged and he was free of symptoms. His blood pressure was 100 systolic, 30 diastolic. During the next ten years he led a normal life with moderately restricted activity, and with the exception of occasional boils on his neck, had no significant symptoms until the time of his present illness.

Physical examination revealed a well-developed and nourished young man in no acute discomfort. There were definite petechiae on the right conjunctiva, both retinas and the right index finger, and questionable petechiae on the abdomen and back. The heart was enlarged to the right and left, extending 3.5 cm. beyond the left midclavicular line. There was a heaving apex impulse, with a loud apical first sound and a definite systolic murmur. There was also a loud, high-pitched, blowing diastolic murmur heard all over the precordium, most marked just to the left of the sternum. The pulse was regular and definitely of the Corrigan type. The blood pressure was 160 systolic, 30 diastolic. The lungs and abdomen were negative. Neither the liver nor spleen could be palpated.

The temperature was 101°F, the pulse 110. The respirations were 25.

Repeated urine examinations were negative except for rare red cells in the sediment of two specimens taken the day after entry. The blood showed a red-cell count of 4,230,000 with 80 per cent hemoglobin and a white-cell count of 16,700 with 72 per cent polymorphonuclears. The sedimentation rate was within normal limits. Two of four blood cultures contained *Streptococcus viridans*. An electrocardiogram showed the inter-ventricular conduction time to be at the upper limits of normal. The T waves were deformed, suggesting an abnormal myocardial state.

During his three weeks' stay in the hospital he had an intermittent fever with almost daily variations between normal and 102°F. On the fourth day he complained of dull, steady, abdominal pain which was unrelieved by defecation or by the passage of gas by rectum. No definite spasm or localized tenderness could be made out in the abdomen. The pain gradually disappeared during the next three days. Several more petechiae appeared on the abdomen and toes, and on the eighth day he had a sudden, sharp pain in the ball of the right foot and at the base of the big toe. Two slightly red, exquisitely tender spots were present in these areas. On the seventeenth day he began to notice a feeling of increasing submanubrial constriction and complained of difficulty in getting his breath. There was little change in his heart except that the systolic murmur at the apex seemed louder and rougher. During the afternoon of the nineteenth day he began to cough continuously, with audible wheezing respirations. The coughing continued for three hours and was finally controlled by codeine and morphine. He raised no sputum and had no hemoptysis. During the period of coughing fine rales were heard at both bases and in the right axilla. The following morning there were definite dullness at both bases, slight distention of the neck veins and moderate cyanosis of the fingernails. He died on the twenty-first day.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD C. CABOT: I can make nothing in particular out of "stiffness of the legs and malaise." If I had nothing but that to go on, I should have no idea whatever.

He was fairly young. That would account partly for his having so low a systolic pressure.

Dr. Mallory has had the habit lately of putting up to me cases that seem so perfectly obvious that I know I am wrong. They are perfect textbook cases which any first-year student can diagnose, and therefore I know there must be something ter-

ribly rare in the background. The question is, What is it? Up to date, I do not know. The history shows that he presumably had an old rheumatic heart lesion, — I suppose on the aortic valve, — and on top of that he had a subacute bacterial endocarditis associated with *Streptococcus viridans*. He had petechiae and tender spots in his fingers and toes dependent on that, these were accompanied by fever and a slight leukocytosis. Then he had something in his abdomen. Of course this is the sort of case where you might easily have an embolus in one of the mesenteric arteries or veins, but it would not disappear in three days and leave him as well as he apparently was. I cannot make any guess as to what was wrong in the abdomen.

His death seemed to be due to a straight failure of the myocardium with a filling-up of his lungs. One could easily imagine that that long attack of unproductive cough had to do with a lesion of the pleura — an embolism under the pleura, for instance, which would give pleural irritation and produce a cough like his. I think nothing of the sort will be shown. He may have had other emboli in the lungs, but in the absence of hemoptysis or other significant symptoms, I do not see how we can say so. His cardiac lesion should be aortic — subacute and chronic. He had a systolic murmur, as almost every cardiac case does, but it could perfectly well be due to the aortic lesion, and I do not see any way to be sure whether there was a lesion on the mitral valve. Mitral disease is commoner than aortic. In young hearts, on a statistical basis, one would say he might have something on his mitral valve if the disease has gone on as long as this. I can find no evidence of mitral stenosis or of any other lesion. His heart should be hypertrophied and dilated.

Is there any reason to suppose he has a coronary thrombosis? I do not see that there is. He can perfectly well have such, however, and the final termination may be due to that, resulting in sudden cardiac failure. But there is nothing to make us suppose it is, and nothing that I can see distinctive of it.

So far as I see, everything is consistent with acute or subacute endocarditis on top of an old rheumatic lesion with terminal heart failure and with presumably multiple emboli. Ordinarily in these cases you find post mortem many more emboli than there is clinical evidence for. I should not be surprised to find them in the spleen and kidneys, though the spleen was not enlarged and the urine showed no blood.

I take it the joints were not examined.

DR. TRACY B. MALLORY. No, if they had been

I do not believe they would have shown anything. It is the sort of case where you get a great many more symptoms than you do pathologic lesions.

DR. CABOT. I take it the main subacute lesion was aortic, whether or not there was anything mitral in addition.

DR. PAUL D. WHITE. I saw this young man on one occasion about ten years ago, when he was a student, to confirm the diagnosis of aortic regurgitation of rheumatic origin. After that I did not see him until Dr. Maurice Fremont-Smith asked me to examine him during the acute illness. As Dr. Cabot said, the usual subacute-bacterial-endocarditis diagnosis seemed to fit the picture until a rather abrupt change took place in his clinical condition, that is, something definitely happened on the seventeenth day when he had the feeling of increased constriction and difficulty in breathing which made him acutely ill. He had not been sick for many weeks, and it was not a terminal case by any means, so far as the ordinary picture of subacute bacterial endocarditis is concerned. I thought he had had a pulmonary embolus.

DR. CABOT. Do you think they are going to find anything in the mitral valve?

DR. MAURICE FREMONT-SMITH. I thought so before he died. He had a perfectly definite, low, rumbling murmur that was typical of mitral stenosis. It seemed that both valves were involved. The striking thing was that this boy was extremely well when he came to my office, with a temperature of only 100°F., with a four-week history of feeling below par and with evidence of petechiae. I sent him to this hospital. He was comfortable except for the three-day period of pain in the abdomen. We could not explain that. There was one symptom not mentioned in the history. He was unable to take a deep breath without increase in the pain. After recovery from this three-day episode he was happy, lying in bed reading and writing until the acute change with an attack of paroxysmal coughing, which was incessant. He coughed for three hours without being able to stop. He was given 4 gr. of morphine. His dyspnea became increasingly evident, and he became slightly cyanotic. He coughed up a little blood about two days after the onset of cough. We were not struck with the signs of congestive failure. We felt at first that it might be acute dilatation with pressure on the recurrent laryngeal nerve because there was not much in his chest. Later on, we examined the chest carefully and I found a bit of consolidation in the right back.

DR. HENRY D. STEBBINS. Could not a rupture of one of the cusps of the aortic valve explain the picture?

CASE 24221

PRESENTATION OF CASE

A twenty-two-year-old, white, American law student entered the hospital with the complaints of stiffness of the legs and malaise.

Three weeks before entry he began to have vague pains in the joints, bones and muscles, particularly in the lower legs, which were somewhat stiff. He also noticed loss of energy, especially during the week before entry. During the two days before entry his ankles and elbows were painful on motion, and there was swelling of his ankles, his shins became sore, and a painful, tender red spot appeared on the index finger of his right hand. He did not feel feverish but was abnormally sensitive to cold. He had had a cold a month before entry, but that had cleared up, and he had had no further upper respiratory infection. There had been no nosebleeds, frequency or nocturia.

Thirteen years before entry, following a sore throat, he had had rheumatic fever, which was acute for one week and subacute for six months. He was kept in bed during that time. Three years later a definite diagnosis of aortic insufficiency was made, although at that time his heart was not enlarged and he was free of symptoms. His blood pressure was 100 systolic, 30 diastolic. During the next ten years he led a normal life with moderately restricted activity, and with the exception of occasional boils on his neck, had no significant symptoms until the time of his present illness.

Physical examination revealed a well-developed and nourished young man in no acute discomfort. There were definite petechiae on the right conjunctiva, both retinas and the right index finger, and questionable petechiae on the abdomen and back. The heart was enlarged to the right and left, extending 3.5 cm beyond the left midclavicular line. There was a heaving apex impulse, with a loud apical first sound and a definite systolic murmur. There was also a loud, high-pitched, blowing diastolic murmur heard all over the precordium, most marked just to the left of the sternum. The pulse was regular and definitely of the Corrigan type. The blood pressure was 160 systolic, 30 diastolic. The lungs and abdomen were negative. Neither the liver nor spleen could be palpated.

The temperature was 101°F., the pulse 110. The respirations were 25.

Repeated urine examinations were negative except for rare red cells in the sediment of two specimens taken the day after entry. The blood showed a red-cell count of 4,230,000 with 80 per cent hemoglobin and a white-cell count of 16,700 with 72 per cent polymorphonuclears. The sedimentation rate was within normal limits. Two of four blood cultures contained *Streptococcus viridans*. An electrocardiogram showed the inter-ventricular conduction time to be at the upper limits of normal. The T waves were deformed, suggesting an abnormal myocardial state.

During his three weeks' stay in the hospital he had an intermittent fever with almost daily variations between normal and 102°F. On the fourth day he complained of dull, steady, abdominal pain which was unrelieved by defecation or by the passage of gas by rectum. No definite spasm or localized tenderness could be made out in the abdomen. The pain gradually disappeared during the next three days. Several more petechiae appeared on the abdomen and toes, and on the eighth day he had a sudden, sharp pain in the ball of the right foot and at the base of the big toe. Two slightly red, exquisitely tender spots were present in these areas. On the seventeenth day he began to notice a feeling of increasing submanubrial constriction and complained of difficulty in getting his breath. There was little change in his heart except that the systolic murmur at the apex seemed louder and rougher. During the afternoon of the nineteenth day he began to cough continuously, with audible wheezing respirations. The coughing continued for three hours and was finally controlled by codeine and morphine. He raised no sputum and had no hemoptysis. During the period of coughing fine rales were heard at both bases and in the right axilla. The following morning there were definite dullness at both bases, slight distention of the neck veins and moderate cyanosis of the fingernails. He died on the twenty-first day.

DIFFERENTIAL DIAGNOSIS

DR. RICHARD C. CABOT: I can make nothing in particular out of "stiffness of the legs and malaise." If I had nothing but that to go on, I should have no idea whatever.

He was fairly young. That would account partly for his having so low a systolic pressure.

Dr. Mallory has had the habit lately of putting up to me cases that seem so perfectly obvious that I know I am wrong. They are perfect textbook cases which any first-year student can diagnose, and therefore I know there must be something ter-

ribly rare in the background. The question is, What is it? Up to date, I do not know. The history shows that he presumably had an old rheumatic heart lesion,—I suppose on the aortic valve,—and on top of that he had a subacute bacterial endocarditis associated with *Streptococcus viridans*. He had petechiae and tender spots in his fingers and toes dependent on that, these were accompanied by fever and a slight leukocytosis. Then he had something in his abdomen. Of course this is the sort of case where you might easily have an embolus in one of the mesenteric arteries or veins, but it would not disappear in three days and leave him as well as he apparently was. I cannot make any guess as to what was wrong in the abdomen.

His death seemed to be due to a straight failure of the myocardium with a filling-up of his lungs. One could easily imagine that that long attack of unproductive cough had to do with a lesion of the pleura—an embolism under the pleura, for instance, which would give pleural irritation and produce a cough like his. I think nothing of the sort will be shown. He may have had other emboli in the lungs, but in the absence of hemoptysis or other significant symptoms, I do not see how we can say so. His cardiac lesion should be aortic—subacute and chronic. He had a systolic murmur, as almost every cardiac case does, but it could perfectly well be due to the aortic lesion, and I do not see any way to be sure whether there was a lesion on the mitral valve. Mitral disease is commoner than aortic. In young hearts, on a statistical basis, one would say he might have something on his mitral valve if the disease has gone on as long as this. I can find no evidence of mitral stenosis or of any other lesion. His heart should be hypertrophied and dilated.

Is there any reason to suppose he has a coronary thrombosis? I do not see that there is. He can perfectly well have such, however, and the final termination may be due to that, resulting in sudden cardiac failure. But there is nothing to make us suppose it is, and nothing that I can see distinctive of it.

So far as I see, everything is consistent with acute or subacute endocarditis on top of an old rheumatic lesion with terminal heart failure and with presumably multiple emboli. Ordinarily in these cases you find post mortem many more emboli than there is clinical evidence for. I should not be surprised to find them in the spleen and kidneys, though the spleen was not enlarged and the urine showed no blood.

I take it the joints were not examined.

DR. TRACY B. MALLORY. No, if they had been

I do not believe they would have shown anything. It is the sort of case where you get a great many more symptoms than you do pathologic lesions.

DR. CABOT. I take it the main subacute lesion was aortic, whether or not there was anything mitral in addition.

DR. PAUL D. WHITE. I saw this young man on one occasion about ten years ago, when he was a student, to confirm the diagnosis of aortic regurgitation of rheumatic origin. After that I did not see him until Dr. Maurice Fremont-Smith asked me to examine him during the acute illness. As Dr. Cabot said, the usual subacute-bacterial-endocarditis diagnosis seemed to fit the picture until a rather abrupt change took place in his clinical condition, that is, something definitely happened on the seventeenth day when he had the feeling of increased constriction and difficulty in breathing which made him acutely ill. He had not been sick for many weeks, and it was not a terminal case by any means, so far as the ordinary picture of subacute bacterial endocarditis is concerned. I thought he had had a pulmonary embolus.

DR. CABOT. Do you think they are going to find anything in the mitral valve?

DR. MAURICE FREMONT-SMITH. I thought so before he died. He had a perfectly definite, low, rumbling murmur that was typical of mitral stenosis. It seemed that both valves were involved. The striking thing was that this boy was extremely well when he came to my office, with a temperature of only 100°F, with a four-week history of feeling below par and with evidence of petechiae. I sent him to this hospital. He was comfortable except for the three-day period of pain in the abdomen. We could not explain that. There was one symptom not mentioned in the history. He was unable to take a deep breath without increase in the pain. After recovery from this three-day episode he was happy, lying in bed reading and writing until the acute change with an attack of paroxysmal coughing, which was incessant. He coughed for three hours without being able to stop. He was given 4 gr of morphine. His dyspnea became increasingly evident, and he became slightly cyanotic. He coughed up a little blood about two days after the onset of cough. We were not struck with the signs of congestive failure. We felt at first that it might be acute dilatation with pressure on the recurrent laryngeal nerve because there was not much in his chest. Later on, we examined the chest carefully and I found a bit of consolidation in the right back.

DR. HENRY D. STEBBINS. Could not a rupture of one of the cusps of the aortic valve explain the picture?

DR CABOT Do you think he had coronary embolus?

DR WHITE Neither rupture of a valve nor coronary embolism was seriously considered. Our attention was focused more on the cough, the blood-spitting and the cyanosis. We should have thought, however, of valve rupture.

DR CABOT Did you think he had infarction in the lung?

DR WHITE Yes

CLINICAL DIAGNOSES

Subacute bacterial endocarditis

Rheumatic heart disease with aortic and mitral insufficiency

DR CABOT'S DIAGNOSIS

Subacute bacterial endocarditis, aortic valve

ANATOMICAL DIAGNOSES

Endocarditis, subacute bacterial, aortic and mitral valves

Ruptured mycotic aneurysm of mitral valve.

Rheumatic heart disease, healed, aortic valve, with aortic insufficiency and left ventricular hypertrophy and dilatation

Pulmonary edema and congestion, acute

Hydrothorax, bilateral, marked

Hyperemia of liver and kidneys

Infarct of spleen

PATHOLOGICAL DISCUSSION

DR MALLORY The salient feature of this case seems to me to be the very sudden cardiac failure in a boy who had had bacterial endocarditis for an apparently short period of time and whose disease up to the morning of the terminal episode was progressing at a slow rate. I doubt if anyone a week before death would have expected a sudden event such as this. The actual findings at autopsy were quite unusual and come nearer to the suggestion of a rupture of one of the leaflets of the aortic valve than anything else that was mentioned, although it was not that.

In a great many cases of bacterial endocarditis involving the aortic valve the vegetations spread down onto the base of the cusps and extend onto the long leaflet of the mitral valve, where they develop on its ventricular surface. Sometimes they penetrate directly through the valve and you get sudden marked mitral insufficiency. In this case the ulceration must have been progressive for a considerable period of time before clinical symptoms appeared because there had been time to pro-

duce an aneurysm between the two surfaces of the mitral cusp, essentially a mycotic aneurysm. This was nearly 3 cm in diameter. At its apex we found a relatively small perforation which I think was probably a terminal event. I should imagine that

Figure 1

in this case the mycotic aneurysm of the valve had been developing for a long time. It then ruptured, and the sudden mitral insufficiency accounted for the rapid onset of failure. The finding of marked bilateral pleural effusions and an extreme grade of acute pulmonary congestion and edema seem to substantiate this hypothesis.

Figure 1 shows the ventricular surface of the mitral valve and the relatively wide area of ulceration of the base of the leaflet, which is really the mouth of the aneurysm. In Figure 2 the valve has been turned over to show its auricular surface, and the aneurysmal sac is evident with a slit-like perforation near the right-hand margin. The sac was very thin walled and consequently has collapsed almost completely, but in life, when it was distended with blood, it must have nearly filled the valve ring and one would suppose it must have produced a marked grade of stenosis.

DR SPRAGUE Was there any rheumatic involvement of the mitral valve?

DR MALLORY We thought there was a little, but it was hard to be sure of. Old rheumatic involvement of the aortic valve was obvious, however. I should add that there was comparatively

little evidence of embolism. There were no emboli in the lungs, and the coronaries were clear. One large infarct was present in the spleen and must

Figure 2.

have been the cause of the attack of abdominal pain. Even the kidneys failed to show the usual embolic glomerulitis.

CASE 24222

PRESENTATION OF CASE

A twenty-one-year-old, white, American woman entered the hospital with the complaints of weakness, nausea, vomiting and epistaxis of seven days' duration.

The patient stated that she had been born with heart trouble and had always lived a restricted life. She was always mildly dyspneic on climbing a flight of stairs and never had been able to take part in athletics. Aside from this she had no other symptoms and had finished high school at the age of nineteen. About fourteen months before entry she began to have pains in the calf muscles, and red macular lesions appeared on her legs which usually lasted a few weeks and then disappeared only to recur later. She was also much weaker than she had been before, tired more easily, and consequently spent most of the time in bed. She remained in bed for practically the entire year before entry. Ten months before entry her urine became dark amber colored, and her physician told her

that she had kidney trouble. At no time did she have frequency, dysuria, nocturia or frank hematuria. During the period from eight to five months before entry she had had three attacks of pleuritic pain in the left lower lateral chest, which lasted from ten to fifteen days and were somewhat relieved by strapping. Seven months before entry she had had some pitting edema of the ankles which disappeared on complete bed rest; there was no edema around the eyes. For the two months before entry she had an unproductive cough. Seven days before entry she had severe epistaxis from her left nostril, losing "well over a quart of blood." This occurred at the time when she expected a menstrual period, and the period itself did not occur. She said that for seven years she had always had mild epistaxis during her menstrual periods. For the seven days before entry she was unable to retain food by mouth because she vomited everything eaten. She was given repeated rectal taps but steadily lost ground. She was very nervous, weak, dyspneic and orthopneic, and had definite fever. For two or three weeks before entry she noticed small, painful red spots at the tips of her fingers and toes.

One of her sisters was known to have congenital heart disease.

Physical examination revealed a very pale, fairly well-developed but undernourished woman, who appeared to be acutely and chronically ill. There were small, round purpuric spots on the dorsa of the feet, and the fingers were slightly clubbed. The heart was very slightly enlarged to the left, and in the pulmonic area, systolic and diastolic thrills and murmurs could be made out. The pulmonic heart sounds were both very loud. A systolic murmur was heard at the apex. The heart rhythm was regular, and the blood pressure was 90 systolic, 30 diastolic, in both arms. The lungs were negative. The abdomen was held tense, but both the liver and spleen could be felt three fingers below the costal margin. There was slight dilatation of the neck veins, but no peripheral edema.

The temperature was 100.5°F, the pulse 125. The respirations were 25.

The urine had a specific gravity of 1.020, contained a large trace of albumin, and the sediment showed 20 red cells, many white cells and a few casts per high-power field. The blood showed a red-cell count of 3,040,000 with 40 per cent hemoglobin, and a white-cell count of 23,600 with 92 per cent polymorphonuclears. The blood Hinton was negative. The corrected sedimentation rate was 0.6 mm per minute. An electrocardiogram showed moderate left-axis deviation and low voltage. A portable x-ray of the chest showed enlarge-

ment of the heart on both sides, and haziness in the right lower lung field

On the third hospital day there were diminished breath sounds and dullness in the lower third of the right lung and slight pitting edema of the ankles. Her skin was cold, clammy and cyanotic, and she had Cheyne-Stokes breathing. She was put into an oxygen tent without much benefit and died that evening.

DIFFERENTIAL DIAGNOSIS

DR. HOWARD B. SPRAGUE: When a patient states that she was born with heart disease the observation may or may not be correct. In the main it is correct because, at an early age, congenital heart disease is to be expected and rheumatic heart disease is very rare under the age of five. We can assume that this patient had been observed constantly from birth, furthermore, she had one sister with congenital heart disease. I think it is fair to assume then that we are dealing with a congenital deformity of the heart and not an early rheumatic lesion. That is supported by the physical findings which show, most particularly, systolic and diastolic thrills and murmurs over the pulmonary area. Systolic and diastolic murmurs may well be called a continuous murmur, and a continuous murmur in that area implies a diagnosis of patent ductus arteriosus. Pulmonary stenosis with pulmonary regurgitation is extremely rare. We have seen only one such case in association with a congenital absence of the pulmonary valves with a very small pulmonary artery, and in that case the diastolic murmur was slight and there was no thrill with it.

There are two main types of patent ductus arteriosus so far as hemodynamics are concerned. The commoner type is that without cyanosis in which the flow is from the aorta into the pulmonary artery and in which, therefore, the arterial blood mixes with the blood of the pulmonary artery and cyanosis does not occur except as a terminal phenomenon when something comes up to raise the blood pressure in the pulmonary circulation, thus producing a flow in the opposite direction. This patient showed cyanosis only as a terminal affair. The other type is that found with a persistence of the fetal blood channels, that is, a flow from the pulmonary artery to the aorta, whereby non-oxygenated blood is shunted past the lungs into the aorta and systemic circulation. There was a mild degree of clubbing of the fingers in this case, which would perhaps help in the diagnosis of congenital heart disease, or perhaps would be related to the infection which we will take up later. The blood pressure finding of 90 systolic, 30 diastolic, is consistent

with patent ductus arteriosus because this condition causes the peripheral signs of aortic regurgitation due to a rapid passage of a portion of the blood from the aorta into the pulmonary artery, thus causing a rapid drop in the diastolic level.

An electrocardiogram showed moderate left-axis deviation. Patent ductus arteriosus puts a strain on both sides of the heart because the right ventricle has to pump against an increased pressure in the pulmonary artery. The left ventricle also has added work because the blood which passes from the aorta directly back to the lungs through the pulmonary artery returns at once to the left heart and has to be re-pumped into the peripheral circulation. This double strain is commonly found in the non-cyanotic type of patent ductus. We might get some help in diagnosis if we found, by x-ray, dilatation of the pulmonary artery from the increase in the pressure.

DR. GEORGE W. HOLMES: I assume that, since the lung fields are dense on both sides, this is a portable film taken when the patient was quite ill. The supracardiac shadow is unusually wide. It is magnified by the portable film but still I think there is no doubt that it is wide.

DR. SPRAGUE: It would support the idea that the pulmonary artery is dilated?

DR. HOLMES: Yes, it certainly would.

DR. SPRAGUE: Something else has occurred in the course of this patient's history to bring on the fatal termination. Infection has apparently arisen. It has resulted in fever, in petechial spots, in what I assume to be pulmonary emboli, and in a certain amount of bleeding from the kidney, probably from miliary emboli. If we are right in assuming that a subacute bacterial endocarditis has been added to the picture, then it would be consistent with our assumption that she had pulmonary infarcts, because, if blood is flowing from the aorta to the pulmonary artery, vegetations which break off would get into the lesser circuit. Such an occurrence has been observed on several occasions in this hospital, so that I believe this is the rather common combination of subacute bacterial endocarditis grafted on a congenital lesion, although it is really an endarteritis rather than an endocarditis or valvitis. The heart itself in the region of the apex has a systolic murmur, of which I can make nothing diagnostic so far as valvular disease is concerned.

DR. TRACY B. MALLORY: I take it you are assuming that the bacterial vegetations are at the actual site of the ductus arteriosus.

DR. SPRAGUE: I should think that they might involve the orifice of the ductus, perhaps on the pulmonary side.

CLINICAL DIAGNOSES

Congenital heart disease with acute or subacute bacterial endocarditis
 Patent ductus arteriosus?
 Chronic nephritis

DR SPRAGUE'S DIAGNOSES

Congenital heart disease
 Patent ductus arteriosus
 Subacute bacterial endarteritis of the patent ductus, with infarcts in the lungs and kidneys

ANATOMICAL DIAGNOSES

Congenital heart disease—patent ductus arteriosus
 Subacute bacterial endocarditis, aortic and mitral valves
 Bacterial endarteritis, pulmonary artery
 Infarcts of lung, spleen and kidneys
 Embolic glomerulonephritis

PATHOLOGICAL DISCUSSION

DR. MALLORY I asked Dr Sprague that last question for the purpose of emphasizing a point which seems to me very interesting. His answer was the natural one and his prediction would usually be correct, but it was not in this case, however. There was a patent ductus, of course—an extremely short one, however. The aorta and the pulmonary artery were in actual apposition and a small round hole led from one to the other. It was impossible to recognize any vessel. The mouths of

the hole on both sides—aorta and pulmonary artery—were free from vegetations. There was a bacterial endocarditis, however, which was on the aortic and mitral valves, and there was another similar vegetation in the pulmonary artery. This lay proximal to the orifice of the ductus and was clearly separated from it by a distance of 2 or 3 mm.

The relation of bacterial endarteritis to congenital heart itself has always been a very mysterious one. Next to rheumatic heart disease it is the most predisposing factor. Ordinarily, bacterial endocarditis *in these cases develops on the deformed valve*, if there is one, or at the site of abnormal connections between the various chambers of the heart, such as a congenital septal defect or a patent ductus arteriosus. Here we have a case with no evidence of deformity of any of the valves, but we have congenital heart disease and bacterial endocarditis combined, and the endocarditis is not at the site of congenital malformation.

A PHYSICIAN Where did it start?

DR. MALLORY I should rather suppose it started on the aortic valve and worked around from there. There was also a thrombus in the right auricle. However, this did not seem to be bacterial in origin.

A PHYSICIAN Were there any pulmonary emboli?

DR. MALLORY Yes, one or two that appeared to be frankly septic in character. There were emboli in the kidneys, which showed a well-marked embolic glomerulonephritis. There was an infarct of the spleen, which was not indicated by anything in the history.

A MODEL STATE INSTITUTION

ENVY is a normal response of the human personality to certain situations, yet it is not considered a virtue but is looked askance upon by society. However one who has lived in Massachusetts during the last year and has been familiar with the humiliating, and to some extent, degrading, developments in the Department of Mental Diseases can properly be forgiven for being envious when reading the report *A Survey of Methods of Care, Treatment, and Training of the Feeble-minded at Letchworth Village* [New York State].

In summarizing the report, Dr. C-E A. Winslow, professor of public health at the Yale University School of Medicine, who served as chairman of the survey committee, says

The first quarter-century of Letchworth Village represents a notable chapter in the history of institutional care of the mental defective. A long succession of governors and legislatures have contributed to its support. An excellent State Department of Mental Hygiene has guided and assisted its development. A great executive, endowed with common sense, sympathy, and courage, built himself into its organization. A Board of Managers of unique vision and devotion—among whom the names of Franklin B. Kirkbride, its vital mainspring through all the years, and of Mrs. E. H. Harriman, who made the Research Department possible, must be mentioned with special gratitude—formulated its program and directed its policies. With the pursuance of that program and the continuance of such leadership the story of Letchworth's second quarter-century should be as significant as the first.

Massachusetts stands at the crossroads. One way leads to continued deterioration. This way involves the use of political patronage, the appointment of second-rate trustees, and a commissioner appointed solely on the grounds of political expediency. The other way calls for a revival of past ideals, a commissioner of great ability and energy chosen only on the grounds of previous achievement and ably and vigorously supported by the governor in his efforts, trustees chosen from the enlightened, socially minded leaders of the community who have no purpose in their trusteeships other than the elevation of the standards of the care of the insane, and individual hospitals with a professional staff which is free from annoyances by selfish politicians and whose members are leaders in their departments of medicine and in their communities, striving only to render a fine account of their stewardship to the people of Massachusetts.

THE ADVERTISEMENT SECTION

PROBABLY few of the readers of the *Journal* appreciate the importance of its advertising contracts to the Massachusetts Medical Society. All members of the Society know that the annual operating loss of the *Journal*—approximately twenty thousand dollars—is covered by an appropriation from society funds and that in consideration of this,

every member whose dues are fully paid becomes automatically a regular subscriber. Fifty-two copies are received each year at an approximate total cost of four dollars, or eight cents a copy.

Improvements in the *Journal* result in additional expense, and unless other sources of revenue are increased, the net result is an increase in the operating loss—a charge to the Society.

The largest source of revenue is from advertising contracts, during 1937 it amounted to more than twenty thousand dollars. The *Journal* has nothing to do with obtaining the majority of contracts, as they are forwarded by the Cooperative Medical Advertising Bureau, of Chicago, a subsidiary of the American Medical Association. This organization negotiates the contracts with firms which advertise nationally in state medical journals, and the only acceptable copy concerns drugs, therapeutic agents and foods which are acceptable to the respective approving committees of the American Medical Association.

Advertising revenue is bound to vary with general business conditions, but there is every indication that the cancellation of contracts that is threatening or has occurred during 1938 is due, in no small part, to lack of interest on the part of the readers in patronizing the advertisers in the *Journal*. Their purpose is not altruistic, but practical, and if there is no indication that their advertisements are being read, they cancel their contracts.

The *Journal* takes this opportunity of humbly requesting its subscribers to read more carefully the advertisement section. Although it is impossible to dress this up as attractively as is done by our plutocratic lay contemporaries, it should be remembered that the products advertised therein represent acceptable therapeutic aids as supplied by manufacturers of the highest ethical standing. Every inquiry to an advertiser makes the *Journal* a better advertising medium and indirectly results in its improvement through increased revenue.

CASE HISTORY No. 74 BLEEDING DUE TO CERVICAL POLYP

Mrs. T. G., a thirty-four-year-old nullipara, was seen on January 20, 1938, complaining of painless vaginal bleeding. She came for examination to find out whether she was pregnant, her last regular period having started July 16, 1937, making her due for delivery the end of April.

The family history was of no value. Her mother and father had died in another country of unknown causes, three brothers and one sister were living and well. Previous medical and surgical history of the patient was negative except for pneumonia in 1931. Catamenia began at fourteen and was regular and of the twenty-eight-day cycle, lasting six days.

A detailed history of the painless vaginal bleeding is as follows. On July 16, 1937, the patient menstruated regularly. There was a period of amenorrhea until October 1, which the patient naturally considered as indicating pregnancy. From October 1 to November 25 there was intermittent spotting, some days fairly profuse and other days just noticeable. At no time was there any pain. From November 25 to January 8 the patient was symptom free except for questionable abdominal enlargement. On January 8 there was a slight flow for one day, and on January 15 flowing necessitated the wearing of a pad.

On examination the abdomen was enlarged to the size of a six-months' pregnancy. Definite fetal parts were palpated, and the fetal heart tones were heard. Pelvic examination revealed an enlarged and soft cervix, with a polyp the size of a large grape protruding from the os. The base of the polyp was very near the external os and easily visualized on speculum examination. Very slight trauma to the polyp caused immediate bleeding.

Considering the location of the polyp, the marked congestion which it showed and the feeling that it was the causative factor of the bleeding, removal seemed advisable. A Ferguson speculum was in-

A series of selected case histories by members of the section will be published weekly.

Comments and questions by subscribers are solicited and will be discussed by members of the section.

serted, the polyp was grasped with a sponge forceps, and the base deeply cauterized. After removal of the polyp there was very slight bleeding from the base, which was further cauterized to control the ooze.

The patient was advised to return home, remain quiet in bed for forty-eight hours, and report any bleeding or untoward symptoms. A report from the patient four weeks after removal of the polyp was completely negative.

On April 10 after a perfectly uneventful primiparous labor lasting eight hours, she was delivered by low forceps of a 7 lb., 14 oz., female child. Her convalescence was uneventful, and both mother and baby were discharged well.

Comment Cervical polyps as a complication of pregnancy are not uncommon. Naturally as the age of the patient advances the possibility of polypoid development increases, since polyps develop secondary to chronic cervicitis of rather long standing. Their diagnosis is made by a history of irregular bleeding, by vaginal examination,—the polyp being felt inside the cervix,—and lastly by inspection. The importance of an early pelvic check-up is shown in this case. If this patient had been seen earlier, the polyp could have been removed when not so congested and with a greater feeling of ease, since naturally the farther along in pregnancy a patient is, the more one wishes to avoid instrumentation of the genital tract, thereby minimizing the chances of infection. Removal and cauterization of the base should cause no trouble so far as the pregnancy is concerned. The possibility of inducing labor is very remote since deep cauterization of the canal is not done. Because of the constant flow and the possibility of hemorrhage during and after delivery, these vascular tumors should be removed during the early prenatal course.

EPILEPSY

John is a fifteen year-old schoolboy, healthy, happy, the pride of his parents and the mainstay of his neighborhood ball team. One day while sitting quietly in his seat at school, John makes a groaning noise, all his muscles become rigid, his breathing stops, his face turns blue, he falls heavily to the floor, his arms and legs jerk violently for a minute or so then thoroughly exhausted he sleeps, and wakes without any knowledge of what has happened. Instead of having a convulsion, perhaps he simply stops what he is doing, stares vacantly for a few seconds unconscious of his surroundings, then resumes his work as though nothing had happened. Or, what is least likely, John may suddenly begin to act as though confused or intoxicated. Though he appears to know what he is doing, he can not be guided or controlled. Then after some minutes he is himself again.

These are three different forms which epileptic seizures may take. An epileptic may have any one, or all these kinds of seizures. They may occur but once in a life time, or may recur at intervals of hours, days or years.

The New Testament contains a vivid word picture of a distracted father bringing to Jesus his son who was subject to convulsions. The disease, said the father, cast the son "into the fire and into the water" and even as he came he fell on the ground and wallowed foaming." Confronted with this medical problem, modern physicians are oftentimes as baffled as were the disciples of Jesus. For centuries both before and after the time of Christ the epileptic was believed to be possessed of a demon. Though we moderns may not believe this, in the fastidious society of the present a "fit" is still looked at with horror and the person who is subject to such attacks is oftentimes cut off from normal associations and employment.

The problem of epilepsy is of importance to the state as well as to the individual. In the United States there are more than 500,000 persons who are, or have been, subject to seizures. Of this number about 40,000 are housed in various state institutions, at a cost for maintenance alone of about \$18,000,000 a year. However, more than 90 per cent of patients are in the community, and if given a proper chance, the great majority of these would be able to live fairly normal lives.

What can be the cause of this terrible condition which like a wild animal leaps upon the innocent and unsuspecting person? Epilepsy would best be considered a symptom rather than a disease. As in the case of other symptoms, headache for example, the cause may differ for different persons or for the same person from time to time. Furthermore, the symptom may not be the result of a single cause but the sum total of several.

First, I shall mention the various causes of seizures. The first cause is heredity. This factor has been over-emphasized. Only about one fifth of patients with seizures know of a relative who was similarly affected. The inheritance of diabetes is as great as that of epilepsy. The 'susceptibility' is present in all who develop the condition, but whether seizures actually appear may depend on additional acquired causes.

Causes which are most likely to start epilepsy in a predisposed individual are injuries or infections of the brain, and the most serious time for such to occur is at birth or in infancy.

Epilepsy may also be stimulated by the failure of some organ in the body. For example, disease of the kidneys may result in the accumulation of poisons which irritate the brain and start convulsions. Then in some patients constipation, poor posture, a hidden infection, a weak heart or an emotional disturbance will precipitate an attack. In every case the seizure originates in the brain, but these other disorders may increase the irritability of nerves and set off an attack. From the aspect of treatment, removal of such last straws may save the camel's back.

How can the cause or causes of seizures in a given individual be determined? Because the causes are different in each person, every person with seizures should have careful physical and laboratory examinations. By no other means can abnormalities either of the brain or of the body be detected. Recently, a most important instrument called the electroencephalograph which makes a record of the electrical currents in the brain has been perfected.

What is the treatment of epilepsy? First, efforts should be spent in correcting any cause discovered by the physician in his examinations. The second line of treatment is to increase the patient's resistance to attacks by the maintenance of robust physical and mental health. The diet

A Green Lights to Health broadcast given by Dr. William G. Lennox on Wednesday, May 18, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

should be varied and should include meat. In the case of children, striking benefit has often been secured through the use of the so-called ketogenic diet—a diet that is rich in fats and poor in starches.

Drugs are not curative but are useful as sedatives to lessen the number or severity of convulsions. Of course drugs as well as other treatment should be at the direction of the physician, otherwise more harm than good may result. Patent medicines, the advertisements of which fill the mailboxes of patients, contain no new or unknown medicines. They are merely one or the other of two well-known drugs, given in unknown doses at exorbitant prices.

Contrary to popular opinion, weakening of the mind does not necessarily or even usually occur. There is need for the education of the family and the public to the attitude that recurring seizures are not dreadful things but are only, like sick headaches, temporarily incapacitating. So far as feasible the patient himself should go ahead in spite of epilepsy. Millions have done this. Many persons of eminence have been epileptic: witness Mohammed, Julius Caesar, Lord Byron, Swedenborg, Napoleon Bonaparte, and many others.

In ending, let me emphasize that epilepsy is more a symptom than a disease. The causes vary in different persons. The finding and the treatment of the causes require careful examinations and long-continued treatment at the hands of a doctor who is both interested and informed. There is great need of a changed attitude on the part of the public toward seizures and toward epileptics. New methods of treatment have recently been found, but there is crying need for more adequate support of research in this disease.

Q My child had a convulsion when he was teething. What chance is there that he will have convulsions later in life?

A According to one investigator, the chances are five times greater than if he had not had any such trouble, in other words his chances of getting epilepsy are about one in forty instead of one in two hundred.

Q What is the difference between luminal and phenobarbital?

A They are the same. Luminal is the name used by a certain manufacturing firm and costs more than phenobarbital.

Q Is there no hope of finding a medicine better than phenobarbital?

A Yes, of course. In fact studies now underway give encouragement in this direction.

Q A friend of mine has a boy about twelve years old who is having very bad convulsions, his mother is very nervous about keeping him at home. Is there any place where such a child can be sent? They do not have much money.

A Eleven of the states including Massachusetts maintain colonies for epileptics where care is given without charge. As you may suppose, practically all the patients in these colonies are physically and mentally far below normal, and there is the question whether a mentally normal child should be sent to them.

Q But this child is quite bright and most of the time is very lovable. The parents do not want to put him away in a big institution. Is there no private place where he can be taken care of inexpensively?

A Unfortunately in spite of the obvious need there seems to be a lack of small adequately staffed and yet in

expensive hospitals for the care and treatment of early cases.

Q If this is such an important sickness why do the doctors not get busy and find out the cause and cure?

A Some doctors are busy. Research work is being carried on in several centers, Boston being a principal one. The Harvard Epilepsy Commission is organized for the purpose of collecting funds to be used in this research.

Q A friend of mine writes me that she is frantic because her child has started having convulsions. She has consulted about all the doctors in her town, but they say they know little about this and just say wait and see if the child will outgrow it. You said that much new knowledge had been gained recently. What I want to ask is this: Are the doctors who know most about this disease explaining what they know to the doctors who know little about it? And also: Is there any place to which a person could write, or is there any printed material that they could get, which would explain about the disease and special treatments that might be tried?

A That is a large double-barreled question. The doctors have indeed formed a society called the League Against Epilepsy for gaining and scattering information. Also there is the Epilepsy Commission of Harvard University to which your friend might write.

Q You spoke about the need of funds. Why would not the prevention and cure of epilepsy be as good a way to employ government funds as finding a cure of hog cholera or building little used roads?

A Why not?

Q You spoke of the necessity of consulting a doctor. How do you explain the following? A neighbor of mine went to many doctors without help, then sent off for a patent medicine and has not had a spell since. Another neighbor had the same experience after going to an osteopath.

A There is great variability in the frequency of seizures. Patients even without any treatment may have long periods, sometimes years in length, without an attack. As for the patent medicine, I have explained that these contain the drug usually prescribed by doctors, but the patient may have taken it in much larger doses than the doctor would consider safe. Excessive doses of these sedatives can make the cure worse than the disease.

Q Would you advise marriage as a means of stopping attacks?

A No. The idea that marriage is a cure is inherited from the Middle Ages.

Q Then does marriage make attacks worse?

A Again no, unless marriage brings added burdens and worries or undermines general health.

Q I still am not clear as to your position about marriage. Do you or do you not forbid a person with epilepsy to marry?

A I do not forbid them. I give the available statistics and explain the pros and cons, and let the patient decide—as he would decide without my advice.

Q Children who begin to have epilepsy should, I suppose, be taken out of school.

A No. They should maintain such mental activity as is consistent with normal exercise, recreation and sleep.

Q But how about the harm to other children which would come from seeing a convulsion? Would you want your own child in the same classroom with an epileptic?

A Of course there is a limit as regards the number and severity of attacks which can be tolerated in a classroom. However, I personally believe that a good many of the nervous ills of adults are due to overprotection in childhood. We cannot be shielded or run away from unpleasant sights all our lives. Early acquisition of a matter-of-fact attitude toward seizures is advantageous. I want my children to associate with and have a sympathetic attitude toward children who are making a brave fight against some physical handicap, and I should object to a beginning or mild case of epilepsy being taken out of school on their account.

Q I know a young woman who has the light, petulant spells which you described. A man wants to marry her, but does not know of her attacks. Ought she to tell him?

A By all means. Aside from the question of fairness, keeping him in ignorance would be legal grounds for divorce in some states.

DEATHS

DEZELL—FREDERICK BURR DEZELL, M.D., of Lynn, died February 2. He was in his seventy-first year.

Born in New York, he received his medical degree from the Johns Hopkins University School of Medicine and then settled in Lynn.

Dr. Dezell was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow, a son and daughter survive him.

LASKEY—EDWARD P. LASKEY, M.D., of 48 Highland Avenue, Haverhill, died April 23. He was in his fifty-sixth year.

Born at Dover, New Hampshire, he attended the public schools there, later graduating from Dartmouth College and receiving his degree in 1908 from the Harvard Medical School. For a year after he left Dartmouth, Dr. Laskey taught at the Weyland High School, serving as sub-master.

After serving a two-year internship at the Boston City Hospital, he started a general practice in Haverhill. Dr. Laskey was a specialist in the use of radium and was one of the first doctors in the vicinity of Haverhill to acquire equipment and use radium extensively. In 1915 he sailed with the Harvard unit, to Falmouth, England, for service in an English field hospital. A former member of the Gale Hospital, he was a consultant on the staff of the Hale Hospital at the time of his death. For many years he served as school physician.

Dr. Laskey was a fellow of the American Medical Association and the Massachusetts Medical Society. He also was a member of the Pentucket Medical Association and the Haverhill Medical Club.

His widow, a son, daughter, brother and sister survive him.

MISCELLANY

COURSE FOR MEDICAL SECRETARIES

Realizing that a doctor needs a secretary with qualifications quite different from those of the ordinary business secretary, Boston University's college of practical arts and letters, in conjunction with the school of medicine, is completing the first year of the new medical secretarial course which was started last fall. The first group of students will graduate a year from this June.

Miss Elizabeth W. Carvell, assistant professor of secretarial studies, supervises the office training, and Dr. Helmuth Ulrich, associate professor of clinical pathology, is chief counselor in medicine. The aim of the course is to make it so practical that when a girl completes her work she can step into a doctor's office and carry on the secretarial work competently without the usual eight months or a year that doctors now have to spend in training a girl for their specialized work.

"A doctor's secretary must be different from any other type of secretary," said Miss Carvell. "Dealing successfully with sick people takes an entirely different psychological outlook than that needed by a girl who works in a lawyer's office or in a bank. Unless a doctor can afford both a nurse and a secretary, his assistant must be able to care for his supplies, to perform first aid, to make blood tests and analyses, all in addition to her general duties of caring for correspondence and bookkeeping."

NOTES

Dr. Harvey Cushing, Moseley Professor of Surgery (emeritus), Harvard University, and Sterling Professor of Neurology (emeritus), Yale University, has been made an honorary member of the Biological Society of Vienna.

Dr. Walter B. Cannon, George Higginson Professor of Physiology, Harvard University, recently delivered the William H. Welch lectures at Mount Sinai Hospital, New York City. The titles were "Some New Aspects of Homeostasis" and "The Aging of Homeostatic Mechanisms."

A grant for an indefinite period of time by the permanent Science Fund of the American Academy of Arts and Sciences has been made to Dr. William C. Boyd of the Boston University School of Medicine. It will enable Dr. Boyd to continue his research in blood groupings, which chiefly concerns a determination of the relations existing between peoples living now and those living in the earliest known period of history.

CORRESPONDENCE

ALEXANDER POPE'S PHYSICAL DISABILITIES

To the Editor: The fact that great physical disability and suffering have never been a bar to distinguished literary achievement is so well known as to require little comment. We have but to think of the Brontës, Heine, Parkman and the great Russian surgeon, Pirogoff, among numerous others.

The following quotation concerning Alexander Pope is interesting in this connection. It is from a volume entitled *From Anne to Victoria: Essays By various hands* (edited by Bonamy Dobree, Cassell & Company, 1937), and is quoted from an "Essay on Pope," by W. H. Auden.

If Pope's social advantages were few his physical charms were even less. Only four feet six in height he was already a sufferer from Pott's disease, the "little Alexander whom the women laugh at," and in middle age was to become really repulsive. So weak as to stand in need of perpetual attendance, extremely sensitive to cold, so that he wore a kind of fur doublet under a shirt of a very coarse warm linen with fine sleeves. When he rose he was invested in a bodice made of very thick stuff canvas, being scarcely able to hold himself erect till they were laced, and he then put on a flannel waistcoat. One side was contracted, his legs were so slender that he enlarged their bulk with three pairs of

stockings, which were drawn on and off by the maid for he was not able to dress or undress himself, and neither went to bed or rose without help. His weakness made it very difficult to be clean. His hair had fallen most all away.

Brookline, Massachusetts.

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

To the Editor In addition to the articles enumerated in our letter of March 31 the following have been accepted

Calco Chemical Co., Inc.

Mandelic Acid—Calco

Cheplin Biological Laboratories

Cheplin's Epinephrine Hydrochloride Solution, 1 1000,
10 cc.

Cheplin's Epinephrine Hydrochloride Solution, 1 1000,
30 cc.

Lederle Laboratories

Viosterol (A.R.P.I. Process) in Oil

Eli Lilly & Co

Ampules Metycaine 10 per cent for spinal anesthesia

Ampules Metycaine 20 per cent for infiltration and regional anesthesia

Wm. S. Merrell Co

Ampules Solution Dextrose 50 per cent, 100 cc.

Parke, Davis & Co

Cevitamic Acid—P. D. & Co.

Tablets Cevitamic Acid—P. D. & Co., 25 mg

Schieffelin & Co

Sulfanilamide Tablets—Schieffelin, 5 gr

S.M.A. Corporation

3 Pyridine Carboxylic Acid (Nicotinic Acid)—
SMACO

3 Pyridine Carboxylic Amide (Nicotinic Acid Amide)—
SMACO

The following product has been accepted for inclusion in the List of Articles and Brands Accepted by the Council But Not Described in N.N.R. (New and Nonofficial Remedies, 1938, p. 508)

Chicago, Illinois.

REPORT OF MEETING

SUFFOLK DISTRICT MEDICAL SOCIETY AND BOSTON SURGICAL SOCIETY

A joint meeting of the Suffolk District Medical Society and the Boston Surgical Society was held April 20 at the Boston Medical Library

The meeting was opened by Dr Conrad Wesselhoeft.

Following a brief presentation of medical society business, Dr Wesselhoeft turned the meeting over to Dr William C. Quinby. Dr Quinby then introduced Dr Augustus Thorndike, Jr., who presented a paper on 'Trauma Incident to Sports and Recreation. Diagnosis and treatment.'

Dr Thorndike pointed out the increasing importance of trauma in competitive athletic sports during recent years, in which time participation in both organized and unorganized sports has been steadily increasing. The most serious injuries in his experience are encountered not in football, as might be expected, but in skiing, baseball and polo. An even larger number of less serious injuries, chiefly sprains, strains and contusions, are encountered in these sports. A detailed knowledge of the lesions involved in these injuries is essential if they are to be given proper treatment.

The fundamental pathologic disturbance is similar in sprains, strains and contusions, the difference depending on the location and extent of the injury. First, there is a tearing of tissue, followed by hemorrhage, which in extent may far exceed the original tear. Subsequently, the hematoma is absorbed, and coincidentally, a fibroblastic proliferation begins the process of repair. In specialized tissues, such as tendons and ligaments, this fibroblastic repair constitutes a permanent weakening, which is the basis for the axiom: Once a sprain, always a sprain.

Contusions may be classified as superficial, joint or muscle contusions. In competitive sports, the most common muscle contusions are seen in the thigh and knee. The usual superficial contusions occur on the lower leg or forearm, and most of them are near enough to the integument to make cold applications feasible in causing local vasoconstriction and, hence, limitation of hemorrhage. Cold should be applied for at least an hour, followed by the application of a pressure bandage. In severe contusions, rest of the injured part is essential, combined with cold applications and pressure. Sponge rubber pressure dressings are very useful in injuries involving joints.

The second stage of the treatment of contusions consists in hastening the resorption process by heat and massage. This should not be undertaken until hemorrhage has stopped completely.

Deep-muscle contusions are occasionally complicated by myositis ossificans traumatica. If this occurs near the end of a long bone or in the region of a joint it may result in permanent impairment of function. It may be suspected by the continued failure of a deep contusion to respond to treatment. X-ray diagnosis is usually not possible until the fifteenth day. The condition usually disappears with continued heat treatment.

The treatment of sprains is based on the same principles as that of contusions, and consists, first, in limiting the hemorrhage as much as possible and, secondly, in facilitating resorption and repair. It is essential to ascertain accurately the pathologic anatomy in each case. By careful palpation it is possible to determine the ligaments involved in any sprain. In ankle sprains, the most common type of injury is a tear of the anterior tibiofibular ligament, injuries to the medial and lateral collateral ligaments are less common. A series of lantern slides were shown to illustrate the treatment of sprains, showing the marked limitation of swelling obtained by the immediate application of cold and pressure bandages. Areas of ecchymosis along the borders of sponge rubber dressings demonstrated the degree to which deep hemorrhage had been limited. The duration of disability depends largely

upon the amount of hemorrhage immediately following a sprain

It was pointed out that strapping an acute sprain with adhesive plaster is a mistaken form of treatment. Strapping should be reserved for the later stages when the swelling has subsided, and is chiefly useful in preventing recurrent sprains. In competitive sports at Harvard, any players who have a history of sprain at any time within several years are strapped each day before entering contact work.

The types of strains were discussed briefly, with lantern slides to illustrate the lesions and their treatment.

The incidence of the more serious injuries, such as fractures, dislocations and internal injuries, is comparatively low in organized sports. The fractures received in football have been less serious than those in baseball and polo. In the unorganized sports, particularly skiing, there is a high incidence of severe injuries. Furthermore, in these sports there are fewer facilities for prompt first aid or medical attention.

Dr Thorndike's paper was discussed by Dr B. A. Godwin, who said that the prompt treatment which had been emphasized was rarely possible in industrial and street injuries. He agreed that the early control of internal hemorrhage determined the length of disability. Dr Henry H. Faxon cited the prevalence of athletic injuries in the younger age groups, which are lacking in full physical growth and development. He suggested that too heavy protective equipment might contribute to some of these injuries. He also called attention to the simultaneous use of a pressure bandage and cold applications in the early treatment of sprains. Dr Charles C. Lund discussed the occurrence of injuries in skiing, which he thought were somewhat exaggerated. He mentioned the need for more adequate first-aid facilities in ski areas. Dr Thorndike recommended the training of lay people for proper first aid work in the unorganized sports.

NOTICES

TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning from ten to twelve-thirty there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. All kinds of tumors are seen, discussed, and when indicated, treated with radium and high voltage x-ray.

Physicians are welcome to visit this clinic and bring patients to the clinic for diagnosis.

AMERICAN CONGRESS OF PHYSICAL THERAPY

The seventeenth annual scientific and clinical session of the American Congress of Physical Therapy will be held co-operatively with the twenty-second annual convention of the American Occupational Therapy Association, September 12, 13, 14 and 15, at the Palmer House, Chicago. Preceding these sessions, the congress will conduct an intensive instruction seminar in physical therapy for physicians and technicians—September 7, 8, 9 and 10.

The convention proper will have numerous special program features, a variety of papers and addresses, clinical conferences, round table talks, and extensive scientific and technical exhibits.

Information concerning the convention and the instruction seminar can be obtained by addressing The American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago.

NUMBER 23

CONSERVATIVE METHODS IN THE SURGERY OF THE CHRONICALLY AND SEVERELY INFECTED KIDNEY

DAVID M. DAVIS*

PHILADELPHIA

I BELIEVE that no one will deny the statement that, of the commoner operations of urology, nephrectomy for pyonephrosis is accompanied by the highest operative mortality. I have found difficulty, however, in determining what this mortality actually is. The term "pyonephrosis" is applied by different persons to different things, the figures given vary tremendously and must, therefore, be regarded with a shrewdly appraising eye. This condition can best be illustrated by a series of mortality figures obtained from the literature. The number of reported series, especially in recent years, is small, as is easily understandable, for the surgery of pyonephrosis is beset with tragedies, it is an unpleasant subject, and there have been no startling therapeutic improvements to encourage the surgeon. The one technical change which has marked a definite advance is preliminary nephrostomy followed by secondary nephrectomy. This procedure has undoubtedly saved many lives, but it is hard to say, from the statistics, just how many.

Table 1 gives the death rates for nephrectomy for pyonephrosis, without regard to whether the nephrectomy was primary or secondary. The figures of Beer, Hryntschak, Scholl and Judd, and Schmidt fall considerably below the others. Hryntschak, as will be seen later, reports a mortality of 29.4 per cent following nephrostomy for pyonephrosis, so that his 24 successful nephrectomies may be regarded as a bit of good fortune. In analyzing the large series of Scholl and Judd, one notes that there were 468 lumbar nephrectomies, including 6 transperitoneal nephrectomies. Of these 54 were extracapsular and 114 subcapsular. Preliminary nephrostomy was carried out in only 7 cases. There were 63 perinephric abscesses, of which 38 were drained some time before the nephrectomy. There is no definite statement of the criteria for the diagnosis of pyonephrosis.

*Professor of genitourinary surgery, Jefferson Medical College; attending genitourinary surgeon, Jefferson Hospital.

Read before a meeting of the New England Branch of the American Urological Association, Boston, November 18, 1937.

Bantz, who has made the most careful statistical study of the subject, finds that there has apparently been a marked improvement in the mortality figures since 1929. He guesses that this improvement is due to better preoperative and postoperative care, particularly ureteral catheter drainage and attention to the fluid balance. However, lumping all the data he has been able to collect, he reaches a combined mortality figure of 27 to 30 per cent for nephrectomy for pyonephrosis.

Table 1 *Mortality Rates in Nephrectomy for Pyonephrosis*

	%
Gerster	14.7
Beer and Hyman (85 cases)	4.7
Hryntschak (24 cases)	0
Bantz (66 cases)	21.2
Bantz (1929-1932)	12.5
Bantz stone (34 cases)	29.1
Rühmer (31 cases)	12.9
Schmieden (138 cases)	23.8
Scholl and Judd (471 cases)	2.5
Schmidt (77 cases)	7.8
Schede (11 cases)	27.2
Combined mortality	27.0-30.0

Table 2 shows those series in which primary nephrectomies are separated from secondary nephrectomies, that is, those done after preliminary nephrostomy. Most of these figures are older, and they run distinctly higher than those in Table 1.

Table 2 *Mortality Rates in Primary Nephrectomy for Pyonephrosis*

	%
Küster	17.0
Gerster (30 cases)	10.0
Schmieden	30.1
Collected by Beer and Hyman	17.0-21.0
Israel	23.0
Bergmann	43.9
Otto	38.8

Table 3 shows the figures for secondary nephrectomies. They are quite comparable with those in Table 2, being in about the same chronological period. The advantages of preliminary drainage appear to be about offset by the fact that the cases so treated are usually more severe.

upon the amount of hemorrhage immediately following a sprain

It was pointed out that strapping an acute sprain with adhesive plaster is a mistaken form of treatment. Strapping should be reserved for the later stages when the swelling has subsided, and is chiefly useful in preventing recurrent sprains. In competitive sports at Harvard, any players who have a history of sprain at any time within several years are strapped each day before entering contact work.

The types of strains were discussed briefly, with lantern slides to illustrate the lesions and their treatment.

The incidence of the more serious injuries, such as fractures, dislocations and internal injuries, is comparatively low in organized sports. The fractures received in football have been less serious than those in baseball and polo. In the unorganized sports, particularly skiing, there is a high incidence of severe injuries. Furthermore, in these sports there are fewer facilities for prompt first aid or medical attention.

Dr Thorndike's paper was discussed by Dr B. A. Godwin, who said that the prompt treatment which had been emphasized was rarely possible in industrial and street injuries. He agreed that the early control of internal hemorrhage determined the length of disability. Dr Henry H. Faxon cited the prevalence of athletic injuries in the younger age groups, which are lacking in full physical growth and development. He suggested that too heavy protective equipment might contribute to some of these injuries. He also called attention to the simultaneous use of a pressure bandage and cold applications in the early treatment of sprains. Dr Charles C. nephrectomy can never have a standardized classical technic for the reason that the conditions it must meet vary too much to admit of this."

In trying to evolve from these intricacies some method of classification which will permit us to evaluate more accurately the success or failure of surgical treatment, I have despaired of achieving a pathological classification simple enough to be useful. It seems to me that surgeons would do better to classify their cases according to the method of operation adopted, which will permit us to advance by studying carefully the diagnostic means of determining which form of operation will be best, and perhaps by developing new or modified methods of operation suitable to the conditions present.

The operations commonly listed as available under these circumstances are lumbar extracapsular nephrectomy, lumbar intracapsular nephrectomy, transperitoneal nephrectomy and permanent nephrostomy.

It often appears to me that a number of surgeons have come to believe that nothing but nephrectomy is permissible. Facing such a case, they have felt that however reluctant one may be, he must proceed to remove the kidney, and that to maintain his professional reputation he must complete the removal, even if in so doing he inflicts trauma which is almost sure to prove fatal. I wish now to ask whether it would not be better to admit frankly that in some cases it is beyond the power of any human being to remove the kidney and save the patient. This being so, we should study and develop other possible methods of giving relief. Such methods actually do exist, and I venture to hope that they may be amplified and improved in the future.

Keeping in mind the assumption that formal nephrectomy may possibly be avoided, if there is good reason for so doing, every effort should be made to obtain the most complete information about the condition present. In some cases the patient's illness may be so severe that immediate operation—usually nephrostomy—is necessary. If so, studies can be carried out later in the manner I shall presently describe. If the illness is not so severe, the usual thorough urologic study is of course carried out. There is no need to go into details about this, but I should like to call attention to an observation made recently which seems to be of some importance. It was made in the case of a woman of fifty who entered the medical ward of the Jefferson Hospital complaining of weakness, malaise, pallor, loss of appetite and slight daily fever, with no localizing symptoms. Pus was found in the urine. A badly infected pair of tonsils was removed without improvement. Urologi-

cal study was then carried out, and the pyelogram shown in Figure 1 was obtained. The patient received several blood transfusions, after which, her condition being improved, operation was performed. The operator was Dr. Walter W. Baker, and I was present at the operation and concurred in the decisions made. We believed that nephrostomy was probably the correct procedure, but decided to explore the kidney with the idea that if it separated easily, primary nephrectomy might be carried out. When the kidney was exposed, the presenting surface was not adherent at all, and separated with great ease from the perirenal fat

Figure 1 *Right pyeloureterogram showing two large round dilated calyces and at least three small irregular cavities near the hilum*

After this encouragement the dissection was continued, but as we approached the region of the hilum very dense adhesions were encountered. A few of them were separated, when it became evident that the ureter and pedicle were embedded in a solid, extremely firm, fibrotic mass. We felt sure that the patient was in no condition to withstand either the separation of these adhesions or an intracapsular nephrectomy, so we concluded the operation, leaving a drainage tube in the pelvis of the kidney. The patient suffered a circulatory collapse after the operation, from which she recovered after a transfusion, but the collapse recurred the next day and death resulted. Her resistance was even less than we had estimated. On returning to the pyelogram after the operation, it appeared to me that this whole situation was clearly shown in it, and that the findings at operation

Table 4 shows some figures as to the results of simple nephrostomy for pyonephrosis. They are all old, and appear to the modern surgeon quite high.

Israel	50.0

Table 5 shows all the figures I could find on the two-stage operation taken as a whole.

It is obvious that figures such as these are confusing and unsatisfactory, and do not permit the establishment of proper standards for the treatment of pyonephrosis. The reason is not hard to discover. The term "pyonephrosis" has always been inexact from the pathological point of view, and unsuitable from the surgical point of view.

Table 4 *Mortality Rates in Nephrostomy for Pyonephrosis*

	%
Küster	17.0
Tuffier	23.3
Hrynschak (17 cases)	29.4

There is no distinct dividing line between pyonephrosis and infected hydronephrosis, and when we say "pyonephrosis" we convey no information whatever as to the existence or severity of complications which may be present, and which are of the utmost importance to the surgeon.

As a matter of fact, it makes little difference to the operator whether the obstructed kidney is filled with pus or with clear, sterile urine, so long

Table 5 *Mortality Rates in Two-Stage Operation for Pyonephrosis*

Tuffier	29.2
Chute (20 cases)	10.0

as there is no perinephric inflammation. We might then create a group of pyonephroses devoid or almost devoid of perinephritic changes. In this group the operative difficulties are minimal. The disease is apt to be of comparatively short duration, but even if the infection is so acute that the patient is extremely ill, and preliminary nephrostomy is the prudent course to follow, the secondary nephrectomy should be easy. The results in this group should be good, provided the opposite kidney is healthy. In short, I believe it would tend to clarify the situation if we abandoned the term "pyonephrosis" for this group and classified the cases as infected hydronephroses, regardless of the character of the contents of the kidney.

This would leave another group in which the extension of the inflammation to the perinephric tissues plays a most important role. Abscesses may occur, and may be single or multiple, large or small, but fibrosis is inevitable, and it is this that determines whether the surgical problem is to be easy or difficult. The fibrosis may involve the entire area about the kidney in an approximately uniform manner, or may be more pronounced in certain areas and less in others. The area most apt to be more densely adherent is that around the hilum of the kidney, where the pedicle, pelvis and ureter are involved. In only a few cases is the fibrosis sharply localized at one point. It may be very extensive about the kidney, and yet not obliterate the line of cleavage between the kidney proper and the inner surface of the true capsule, even though the latter be greatly thickened. It is upon this pathological fact that the operation of subcapsular or intracapsular nephrectomy is based. It avoids the separation of dense and widespread adhesions, in which lies the danger of producing traumatic shock, or injuring other vital organs such as the vena cava, aorta, pleura, intestine, pancreas, liver, and so forth.

This operation, however, does not solve all the problems. With increasing damage to the kidney, the line of demarcation between it and the capsule may be partly or entirely obliterated, and in the extreme degree of this change, nothing may be left but an infected cavity representing the pelvis, surrounded by a dense mass of scar tissue in which it is difficult or impossible to find, even with the microscope, any remnant of kidney tissue. To speak of performing nephrectomy in such a case must be regarded as the result of wishful thinking, because there is really no longer any kidney—it has been destroyed and its boundaries cannot in any way be determined.

In formulating the problem presented by such kidneys, three other factors must be considered. First, there may be a congenital anomaly of the kidney, such as horseshoe kidney, double kidney, ectopia, or polycystic disease, all of which increase the responsibilities and difficulties of the surgeon. Secondly, there may be disease of the opposite kidney, which requires simultaneous treatment or restricts the alternatives available to the surgeon. Thirdly, general disease may be present, and diminish the ability of the patient to withstand extensive surgical procedures.

It must be obvious from this exposition that even in the restricted group of pyonephroses complicated by perinephric fibrosis there are the greatest variations in operative suitability and consequently in prognosis for recovery from operation. It is indeed true, as Chute has said that "secondary

tions injected in the drainage tube will tell us whether any of the pelvic contents are reaching the bladder. Roentgenographic studies are the most instructive. While ordinary retrograde pyelography is possible in many cases, it is usually easier to inject the pyelographic medium directly through the drainage tube. Fluoroscopic observation during the injection shows whether any of the fluid reaches the bladder, and if so, how easily. If the tube is clamped or plugged, one can see how quickly and completely the pelvis empties. Lastly, if there is any chance that ureteral drainage has become adequate, blocking of the drainage tube for twenty-four hours or so answers the question. It is by careful attention to these methods and thoughtful interpretation of the findings that we may hope to make the accurate and reliable preoperative diagnoses which will permit the selection of the best and least dangerous procedure to relieve the patient.

I can add to the literature no large body of statistics on the surgery of pyonephrosis. However from the records I have available, I have taken 12 cases which I think can fairly be placed in the category of the extremely difficult cases of pyonephrosis with extensive perinephric fibrosis. I have eliminated all frank renal tuberculosis, and a few other cases in which severe perirenal fibrosis was present, but was due to causes other than pyonephrosis, such as trauma. Of these 12 cases, 4 had, in addition, perinephric abscess. Three cases were treated by extracapsular nephrectomy, with 1 death from peritonitis a week after the operation, and 1 other case in which secondary complete ureterectomy was necessary to obtain a cure. One case, with a double kidney and dilated ectopic ureter opening into the urethra, was treated by nephrostomy, followed by resection of the diseased half of the kidney. The ureter was not removed and by good fortune gave no trouble. In 2 cases nephrectomy was attempted and abandoned, and both these patients died. One case has been described, and the other occurred a good many years ago. I now believe that nephrectomy should not have been attempted in the latter case. Autopsy showed complete fibrosis of the kidney and obliteration of the line of cleavage. One case treated by intracapsular morcellation, 3 treated by nephrostomy and subsequent ureteral dilatation and 2 treated by prolonged drainage gave excellent results and will be described in greater detail. The last 5 of these cases represent the sort of conservative handling which may perhaps come to be granted a place in the treatment of these difficult cases.

Case 1. A 37-year-old married woman had never been pregnant, but a gynecological operation had been per-

formed 4 years before. One year before admission there began pain in the right upper quadrant, radiating to the groin, and frequent and painful urination. During the year she lost 70 lb., becoming extremely emaciated. There

Figure 2 Diagrammatic representation of the operation performed in Case 1. One blade of the clamp has been thrust into the kidney near the hilum. The reflected and thickened capsule is not shown.

was a large, tender mass in the right kidney region and an irregular fever. Immediate nephrostomy was performed, with release of nearly a quart of pus. Both pus

Figure 3 Operation partly completed. The hemostatic sutures and ligatures are shown.

and urine contained *Escherichia coli communis*. Improvement was rapid and uninterrupted. The drainage tube was unfortunately removed by her family physician after 3 or 4 months, but the fistula remained open and at the end

might have been foreseen. As you will note in the picture (Fig. 1) there are in the upper and outer parts of the kidney two large, round, smooth cavities, evidently dilated calyces, while below and medially situated are several very irregularly shaped cavities, each much smaller than the round cavities. The pressure in a closed cavity is the same at all points, and the good distribution of the pyelographic medium shows that all parts of the pelvis communicate freely with one another. Therefore, the appearance of this pyelogram can only mean that the upper and outer calyces have dilated freely and easily and without hindrance from any fibrotic change in the capsule or perirenal tissues, while in the more central portion of the kidney the calyces have dilated but slightly and irregularly because they are surrounded and confined by an extensive fibrotic change. Had we observed this fact, we should have made a simple and rapid nephrostomy, and it is quite likely that the patient's life might have been saved. Since this incident, I have restudied a number of pyelograms, and believe that it may be possible to draw from the nature of the pelvic outline fairly accurate inferences as to the degree and location of perinephric fibrosis.

If the surgeon believes that secondary nephrectomy is or may be for any reason inadvisable, and wishes or hopes to avoid it, the nature of the problem depends upon whether or not the kidney is still able to secrete urine.

If the kidney is still secreting considerable quantities of urine, nephrectomy can be avoided only by providing adequate drainage. Unless we accept the undesirable alternative of a permanent nephrostomy, this may be accomplished only by restoring the function of the ureter, by dilatation or by plastic operation. In considering this matter, we should remember that in the early days of urology the great pioneer Albarran recognized the possibility of restoring ureteral drainage, and attempted to place a retention catheter, as large as possible, in the ureter at every nephrostomy. The infection is not necessarily an insuperable obstacle. Let me observe that if an infected kidney can be kept under control by drainage through a rubber tube, it may be controlled equally well by thorough drainage through the ureteral tube.

If the kidney secretes only a small quantity of urine, efforts may be made to remove remaining portions of parenchyma by fragmentation, to interfere with the remaining blood supply, or to cause atrophy by the application of chemicals or deep x-ray. Chemicals such as tannic acid, weak formaldehyde and trichloroacetic acid have been suggested, but I have had no experience with them. Schofield speaks highly of the value of x-ray for

this purpose. If such efforts are successful, urinary secretion is permanently suppressed, and the considerations outlined in the next paragraph then apply.

If the kidney produces no urine, we are simply dealing with an infected cavity. This cavity may be only the renal pelvis, but if there is a low ureteral obstruction, it may be the pelvis and a dilated ureter, or there may be added the cavity of a perinephric abscess. Whatever it is, it will heal if adequate drainage is provided for a sufficiently long period. The drainage aperture must be of generous size, and drainage materials must be kept in place until firm healing occurs from the bottom of the cavity.

In all such cases very careful thought must be given to the ureter. If the ureter is not dilated, we may assume that the obstruction giving rise to the pyonephrosis is at or near the ureteropelvic junction, and no especial attention need be given the ureter. If, on the contrary, the ureter is dilated, it cannot be disregarded, no matter what kind of surgical attack is employed. The nature of the obstruction then becomes important. If it is a dilatable stricture, suitable dilatation may have very favorable effects, and indeed change the whole nature of the problem. If the obstruction is for any reason not amenable to dilatation, we must deal with the ureter in some positive way, and it is often desirable to do so before attacking the kidney. This is true even if an intracapsular nephrectomy is contemplated, as in this operation ureterectomy is difficult or impossible. The ureter can be dealt with by some plastic or other operation designed to restore its patency, by removal through an inguinal incision, or, if neither of these is possible, by bringing it to or near the surface and draining it thoroughly. Such operations should be carried down to the point of obstruction, wherever it is, as a retained lower end of the dilated ureter is much more apt to give trouble than the upper end. Neglect of the ureter does not always result in failure of an operation on the kidney, but often enough so that no prudent surgeon should be guilty of such neglect.

In deciding what to do in the region of the kidney, observations at the operating table are of the greatest value, as there is no other absolutely certain way to determine whether the kidney falls within the extremely difficult classification. If nephrostomy is done, numerous and extremely valuable methods of study are available after drainage has been provided. The presence or absence of urine in the drainage can be determined. In doubtful cases, the urea content is decisive. Functional studies can be carried out with phenolsulfonphthalein or indigo carmine. Colored solu-

Case 3 A 47-year-old man entered the surgical ward of the Jefferson Hospital complaining of extreme pain in the right side of the abdomen, with muscular rigidity, fever and leukocytosis. An emergency laparotomy was performed, and an essentially normal appendix was found. A mass was palpated in the region of the right kidney. The symptoms continued and in fact grew worse, with high fever and chills, so that a few days later, after transfer to the Urological Service, operation on the right kidney was necessary. Figure 7 shows the intravenous urogram

Figure 7 Case 3 Right pyeloureterogram. Note the large opaque mass occupying the right half of the upper abdomen, the dilated pelvis and the mottled appearance due to a poor mixture of the pyelographic medium with thick pus. The arrow marks a ureteral calculus.

with dilated pelvis lying in a large area of density, and a questionable stone shadow in the region of the lower ureter. A large perirenal abscess was found, with marked fibrotic changes about it. Beneath the abscess could be palpated a large, flabby kidney, and a fistula was found leading to the pelvis. The abscess and the kidney pelvis were drained with rubber tubes. Improvement was immediate and pronounced, and subsequent pyelographic studies, made by injecting the medium through the drainage tubes, showed the pelvis enlarged, and the ureter dilated down to a point just below the iliac artery, where a good sized calculus was lodged. The patient felt so well that he importuned us to remove the tube, but this was not done until, as a result of repeated ureteral dilatation as high as 16 French, the stone was passed. Since the injection of colored fluid now demonstrated excellent ureteral drainage, the tube was removed. The sinus immediately closed, and the state of well-being was such that the patient neglected the advice given him to undergo systematic ureteral dilatation. He gained about 30 lb,

but in about 4 months fever and pain recurred and the loin sinus reopened and discharged large amounts of pus. There was some difficulty in passing an instrument up the ureter, but once it was accomplished the sinus healed at once. Subsequently the ureter was dilated at increasing intervals with a No 14 bulb, and the patient has remained perfectly well. Figure 8, an intravenous urogram, shows

Figure 8 Case 3 Intravenous urogram. The ureter has been dilated, the stone has passed and the nephrostomy tube has been removed. Note the small size of the pelvis and the sharp calyces.

how markedly the right renal pelvis had contracted and returned toward normal.

Case 4 A 54-year-old man had had for 16 years recurrent attacks of pain on the right side, and 10 years before admission a large stone had been removed by operation from the right kidney. Two years later he had passed blood. For 7 years he had been known to have diabetes, which was controlled by dietary treatment. For 5 years he had passed blood and pus at frequent intervals and had lost 50 lb. For 3 weeks there had been pain in the right side, fever to 101°F and hematuria. Examination showed the typical features of horseshoe kidney (Fig 9), with marked hydronephrosis and hydroureter on the right, narrowing of the ureter at its lower end and a few stone shadows in the kidney area. The urine contained pus and a few streptococci. Urine from the left pelvis was normal, with excellent function (Fig 10), but only a trace of phenolsulfonphthalein came from the right side. An operation, planned to be a heminephrectomy, was carried out. After a very thick Gerota's capsule had been cut through, a large perinephric abscess

of 6 months there were no bad effects, except that x ray studies were rendered impracticable. Secondary nephrectomy was attempted. The capsule was 2 cm thick and very tough, and the ureter, pelvis and pedicle were imbedded in such extensive masses of scar tissue that it was

Figure 4 Operation completed The pelvis is left widely open, drains were placed well down into the pelvis

considered unsafe to free them. After dividing the capsule and pushing it away from the kidney as well as possible, one blade of a large curved clamp was thrust through the kidney cortex into the pelvis as far down toward the hilum as possible (Fig 2). The kidney was cut away above the clamp. By repeating this process, the entire pelvis was encircled (Figs 3 and 4). Hemostasis was obtained by mattress sutures or ligatures, according to the length of the bite of the clamp. The entire extrarenal pelvis, ureter and pedicle were left behind, but all parenchymal tissue appeared to have been removed. Drains were placed in the pelvis. A tube was kept in place about 2 months, being shortened only as it was forced out by the healing process. By this time healing was complete, and the patient has remained perfectly well and free from symptoms. I include this case to illustrate a variant in the method of performing intracapsular nephrectomy. It has probably been used before, but I have not found a description of it.

Case 2 A 53-year-old woman had severe pain in the right kidney region, with fever and chills. Examination showed the right kidney pelvis dilated and filled with pus, and the pyelogram (Fig 5) aroused a suspicion of polycystic kidney. The patient was so ill that a right nephrostomy was done, at which time the diagnosis of polycystic kidney was confirmed. While she was convalescing from this operation the other kidney became heavily infected, and left nephrostomy was necessary. The pelvis again was found to be full of pus (Fig 6). Ten days later the fever recurred, and exploration revealed a large abscess around the upper part of the left ureter. This was drained, and all the drains were maintained for nearly 8 weeks. During the first half of this period the patient had continuous high fever and chills, but after these subsided the ureters were cautiously dilated, as it was out of the

Figure 5 Case 2 Right pyeloureterogram showing dilatation and deformity characteristic of a polycystic kidney. The ureter is irregular, but not markedly dilated.

question to consider removal of either kidney. As a result of this, all the sinuses healed and the patient was able to leave the hospital in good condition, although of course the urine was still infected.

Figure 6 Case 2 Left pyelogram showing dilatation and deformity.

and was greatly dilated and convoluted in its lower portion, which extended almost to the bladder (Fig 12) I felt that nephrectomy, to be successful would have to be preceded by removal of this hugely dilated and infected ureter. This was accordingly undertaken, and was found to be very difficult. The peritoneum was extensively torn. A small portion of the lower end of the ureter had to be left in place, and was thoroughly drained. The upper end

were extruded by the healing process, and no urine was ever detected in the drainage. Both sinuses were completely healed 4 months after the last operation. The patient was under observation for 6 months after healing was complete. He felt very well, had no symptoms and gained much weight. The mass in the right kidney

Figure 11 Case 4 Right pyeloureterogram made by injecting Skiodan solution through the nephrostomy tube. The ureter has been dilated. Note the small size of the pelvis and that most of the solution is in the bladder.

was brought as near the surface as possible and drained with a large tube. This procedure was so arduous that it was considered wise to postpone the attack on the kidney. The incision healed per primam, and 3 weeks later the old sinus was excised and its lower portion split with a view to intracapsular nephrectomy. Neither kidney tissue nor line of cleavage could be found although the cavity representing the pelvis was widely opened. During this dissection several small arteries were divided and either ligated or closed by packing. This may have assisted in completing the atrophy of any small remnants of secreting tissue remaining. The entire large mass of scar tissue could have been removed only by sharp dissection, and I considered this unjustifiable in the absence of all landmarks, so that large drains were inserted and the operation was concluded. The drainage sinus from the lower end of the ureter healed very promptly. Drainage tubes were kept in the sinuses leading to the upper end of the ureter and to the kidney pelvis until they

Figure 12 Case 5 Diagram representing the x ray findings after injecting Skiodan solution through the drainage sinus. Note the large dilated ureter and that no solution has entered the bladder.

region was not tender in the slightest degree, and became markedly smaller. I feel that this treatment was by far the best solution for this young man, and cure would have been impossible so long as the dilated ureter remained in place.

Case 6 A 43-year-old, married woman, with two children, complained of frequent, painful and urgent urination for 2 years, and a painful and tender swelling in the right flank for 5 weeks, with loss of weight of 10 lb. Seven years before she had been told that she had a floating right kidney. Ureteral catheterization was impossible. At operation a perinephric abscess was found, extending down into the iliac fossa. It and a large pyonephrotic cavity were drained. Following the operation, no urine was detected in the drainage at any time. A pyelogram was made by injection through the tube (Fig 13), showing a dilated pelvis. There was no ureteral filling, so that the underlying obstruction was undoubtedly at or near the ureteropelvic junction. The patient did so well that nephrectomy was attempted 9 days later. The operation note made at this time states:

"The incision has healed in a remarkable way in spite of the presence of so much pus. There has never been any sign of urinary drainage. The old incision is reopened with some difficulty. The perirenal fat is extremely indurated. Efforts are made to dissect down

was opened. Within the abscess lay the kidney, which was densely adherent. It was felt that the circumstances, including the existence of the isthmus, did not permit intracapsular nephrectomy, and indeed that the excessively dense adhesions in every direction would prevent one from ever removing the kidney with any degree of safety. Drainage tubes were therefore placed in the abscess cavity

necessary, after which dilatation was eventually carried to No 16½ French. The posterior edge of the vesical orifice, which was prominent, was incised with the Collings electrode. After this, fluoroscopic examination showed that Skiodan solution injected in the nephrostomy tube passed quickly and completely to the bladder (Fig 11)

Figure 9 Case 4 Right pyeloureterogram showing a dilated pelvis mottled appearance a deformity characteristic of a horseshoe kidney and a dilated ureter with stenoses in the lower third. The lower border of isthmus can be seen

Figure 10 Case 4 Left pyeloureterogram showing some dilatation and deformity characteristic of a horseshoe kidney. Note the absence of a mottled appearance in the pelvis

and in the pelvis with the idea that the nephrostomy would probably have to be made permanent. The convalescence was extremely complicated. The diabetes was difficult to control. Subacute postoperative gangrene developed in the incision, requiring a wide excision of skin and subcutaneous tissue, protracted dressing with zinc peroxide paste and eventual skin grafting. First one epididymis and then the other became acutely inflamed, but neither suppurated. Acid fast bacilli were found in the urine once, but later studies were negative. These misfortunes kept the patient in the hospital 3 months, during which time purulent urine drained constantly from the nephrostomy tube. I decided to attempt to restore ureteral drainage, hoping to be able to dilate the stenosis demonstrated in the lower ureter. Ureteral meatotomy was

The tube was therefore tightly corked for 3 days, with no untoward symptoms whatever. It was then considered safe to withdraw it, and the fistula healed promptly. Eight months later the patient had gained 50 lb, felt very well with no symptoms whatever and was hard at work. The urine still contained pus and a few streptococci. I feel that further operation in this case would have been unjustifiably dangerous, and although an infected kidney is still present, it can be controlled by an occasional ureteral dilatation.

Case 5 This patient was a 26-year-old man, at the age of 5, a large right hydronephrosis had been drained, and the resulting sinus had discharged purulent material ever since. Two subsequent operations had been performed at one of which a large stone had been removed, and possibly part of the kidney. Examination showed a large, irregular mass beneath the sinus. The urine was perfectly normal and the right ureter evidently completely occluded, as no ureteral orifice could be found with the cystoscope. The sinus was injected with Skiodan solution and was observed under the fluoroscope, and films were taken. They showed an ovoid mass beneath the sinus, and in the middle of it the Skiodan outlined an irregular kidney pelvis with large, rounded calyces. The Skiodan had also penetrated the ureter, which was very narrow near the kidney,

parenchyma left, and one need not worry about hemostasis. The blood supply is much less than normal, the situation is less formidable, and the control of the blood supply is easy.

The other problems are very diverse and very complicated. I am rather surprised that Dr. Davis has not found abscesses working downward. In our series there were perirenal abscesses gravitating as far as Poupart's ligament. The whole flank was transformed into an infected space. There is no doubt that conservative treatment is the proper kind so long as it is really conservative. In some cases if the patient seems not to be doing well a nephrectomy should be performed.

The problem of the bilateral case is a very difficult one. In my group of 150 cases, 80 or more were associated with stones in one way or another. They either formed the inciting cause of the pyelonephrosis or were incidental to it.

DR. E. GRANVILLE CRABTREE. In the handling of this group of cases Dr. Davis has brought out many important points. I wish to emphasize the necessity for prompt secondary operation in case it has to be done. In approximately a month's time the patient has had the advantage of adequate drainage of the suppurating process, even in cases where the process is in the parenchyma of the kidney itself. At the end of this time, one does not find the dense scar tissue which makes secondary operations almost impossible. I note in one of Dr. Davis's cases the great difficulty in handling scar tissue. I make an effort to reoperate within a month, because later than that the scar tissue becomes very difficult to deal with.

DR. CLYDE L. DEMING. Dr. Davis has clearly outlined the way to handle kidney infections in a conservative manner by two-stage nephrectomies, first draining the ureters and leaving the kidney in. I have recently looked over our list of nephrectomies for pyelonephrosis. There are 35 or more, and there has been only 1 death. This is a better record than I find in the literature. There are large numbers of cases where kidneys have been preserved, and 1 case that I should like to cite. A woman with bilateral pyelonephrosis had only 10 per cent dye excreted in two hours. She was operated on nine years ago by conservative measures and the pus was drained by nephrostomy and later by dilatation of the ureters. The renal function has remained about the same, the patient does her own housework and looks quite well. In cases with pyelonephrosis there have been no deaths from nephrectomy during the last few years, we have tried to treat these cases conservatively by two-stage operations.

I have lost cases by doing a primary nephrectomy and have wondered why there was shock. This occurs within two to twenty-four hours after operation, and there seems to be no way of combating it. Recently there have been reported a number of cases in which the patients died of shock and in which autopsy showed a single adrenal. That brings to my mind a new possibility which I think has not been brought out, namely in some cases where we attempt nephrectomy there is only one adrenal. We all know that we sometimes injure the adrenal in doing a nephrectomy, and it is possible that these deaths may be explained by injury to this single gland.

In doing two-stage nephrectomies one finds a rather

marked diminution in the size of the kidney, so that the operation is very much easier, the line of cleavage is more distinct from the adrenal, and one is less likely to injure the gland in removing the kidney.

Dr. Davis did not bring in the factor of different types of infection in discussing the treatment. I wonder if he has formulated any opinion as to the types of infection in which special kinds of surgical treatment should be applied.

DR. J. DELLINGER BARNEY. Dr. Davis has reviewed the subject most thoroughly. I think one should lay down the rule that each case is a law unto itself. It is surprising that one can leave behind a great amount of inflammatory tissue in the form of perirenal fat and capsule in cases of intracapsular nephrectomy. It is unwise to remove it, and to do so takes as much time as does a whole nephrectomy. I can think of only one or two cases where I have later removed this tissue. Nature seems to have been kind in these cases, and it is poor judgment to take out the tissue when it can be left behind. Some of the older men used to tell me to remove everything possible, but I have found this inadvisable.

Dr. Davis (closing). Dr. Quinby has raised a point which I did not mention, that there are a few cases which do not do well after nephrostomy drainage. That is true, and I think it is due to the conformation of the kidney pelvis itself. It may be difficult to obtain good drainage by a single drainage tube or even two. I recall one case where it was obvious that nephrostomy drainage would be unsatisfactory, and I proceeded to perform a primary nephrectomy. The patient was extremely ill and I feared she would die of operative shock, but fortunately she made an excellent and rapid recovery. I think this was one case which would not have done well with nephrostomy drainage.

Dr. Crabtree speaks of the time of secondary operation. I agree with him. The patient who was operated on six months later went too long, owing to her failure to return at the recommended time. On the other hand in a good many cases the patient is so debilitated because of the first illness that one feels it desirable to postpone secondary operation until the patient's condition has improved. Patients are often quite emaciated and anemic, and it takes two or three months to build them up sufficiently to withstand the operation.

As Dr. Deming has said, one often finds the adrenal extending onto the kidney. In some cases where we have done extracapsular nephrectomy, an intracapsular operation would have been better.

As to the types of infection, those due to *Proteus* bacilli seem to be the most difficult ones to treat. If one can get thorough drainage with two or three drainage tubes and possibly a Dakin's tube as well, and irrigate the kidney with acetic or phosphoric acid in dilute solution, he can deal successfully with a *Proteus* infection.

I was delighted to have Dr. Barney confirm my impression that it is correct to leave large amounts of fibrous tissue behind. If it is necessary to drain, the most important point is keeping the drainage material in place for a long time until the wound can heal from the bottom with granulation tissue. I think it is the early removal of drainage tubes that gives trouble in these cases.

to the kidney around the drainage sinus, but nowhere is any recognizable kidney tissue found or any line of cleavage indicating the capsule. The finger in the drainage sinus feels firm trabeculae characteristic of a hydronephrotic kidney pelvis. Efforts are made in various directions to dissect the kidney and posteriorly the vena cava is exposed. The finger is passed below the lower pole of the kidney, but it is impossible to tell whether this is inside or outside the perirenal fat. The peritoneum is densely adherent to the kidney anteriorly and medially.

"In view of these findings and of the fact that all this palpation discloses no noteworthy kidney sub-

Figure 13 Case 6 Right pyelogram made by injecting sodium-iodide solution through the nephrostomy tube. Another drainage tube is in the perinephric abscess cavity. Note that none of the solution has entered the ureter.

stance, and of the fact that no urine has been secreted through the drainage tube, it is decided not to attempt further to remove the kidney. I feel that removal of the kidney here would be extremely dangerous to the patient's life. A drainage tube is placed in the kidney pelvis and packed around with gauze. A second drainage tube is placed in the abscess in the iliac fossa. Cigarette drain to the postrenal space. Closure by through and through sutures of silkworm gut.

I think that the abscess in the iliac fossa will heal promptly. The tube will be kept in the kidney pelvis as long as possible, preferably 2 to 4 months. I believe that the sinus will then close and there will be no further drainage. Should any further operation be necessary, it should be transperitoneal on account of the destruction of all landmarks about the kidney."

The tissue removed for examination showed no trace of any renal elements. The tube remained in place about

2½ months, when it was forced out by the healing process. The patient has remained well and entirely free of symptoms for nearly a year, and has gained about 30 lb.

* * *

I am sure that every urologist has had experiences similar to mine in dealing with pyonephrosis. When the results have been poor, I believe that they are usually due to the extreme difficulties inherent in the situation. I venture to make a plea that there be more discussion of these difficulties, and of means of circumventing them, and hope that even if my contribution is considered of small importance, it may stimulate further consideration of these knotty problems.

DISCUSSION

DR. FLETCHER H. COLBY. Dr. Davis has given us a very interesting paper. He brings up a very difficult problem and one which we all meet. His solution is new to me and is probably new to many others. His experience in pyogenic infections of the ureters has been similar to my own, which is that ureters infected with tuberculosis seldom have to be removed, those infected with pyogenic organisms are much more apt to cause trouble.

DR. WILLIAM C. QUINBY. I think we are very fortunate in having such a clear-cut picture of this subject. I had reason to look up this type of case in our clinic rather recently, and while I do not have the exact figures based on the approximately 150 cases operated upon, there was a mortality of 13 per cent, this includes drainage cases as well as nephrectomies of all kinds. The patients are usually very sick, as we all know, and each demands one's best judgment as well as one's most daring operative skill. There is, I think, one thing worth bringing out, that is the importance of handling the infection and at the same time of providing adequate hemostasis. Cases fall roughly into two such groups so far as the diagnosis is concerned. If the infection is relatively recent, and if one finds a very large, swollen, soft, succulent kidney thoroughly infiltrated with pus, the danger is greater than with a kidney whose condition will be changed for the better by prolonged drainage through nephrostomy. However, where there is only a relatively large or small pus sac the problem is that of handling the infection rather than one of vascular supply. As Dr. Davis has pointed out in one or two of the cases he mentioned, there is often very little

with 1 patient in this series, in whom a difficult forceps delivery was complicated by partial inversion of the fundus of the uterus. About forty-eight hours after delivery a tumor mass was palpated in the pelvis which at operation proved to be a walled-off abscess in contact with a small rent in the posterior wall of the bladder.

Disease of the bladder wall is an occasional factor in the causation of rupture. Alton² has reported a case of intraperitoneal rupture wherein at autopsy the entire wall of the bladder was found to be necrotic, owing to tuberculous infection which evidently originated in the left kidney. Dixon and Strohl¹³ report an unusual case of spontaneous rupture of the bladder in a patient with syphilis of the central nervous system.

Saphir and Shapiro³³ reported a case of seemingly spontaneous intraperitoneal rupture in which microscopic examination of the bladder wall showed almost complete replacement of the muscularis with fat. Careful microscopic examination of bladder walls of patients coming to autopsy from diseases not related to the urinary tract showed 2 cases of fatty infiltration in 30 bladders examined, bladder function during life had apparently been normal. These cases suggest fatty infiltration of the bladder wall as an occasional etiologic factor in the production of so-called spontaneous rupture. No such findings were recorded in the present series.

The term "spontaneous rupture" is reserved for cases in which there is no history of trauma and no demonstrable disease of the wall of the bladder. Three such cases were found in this series, of which 1 had a postprostatectomy stricture of the urethra. Genitourinary disease was not demonstrable in the other 2 cases. Of these, 1 was of particular interest in that the patient, a man of forty-eight, was awakened from a sound sleep by sudden, severe abdominal pain which he tolerated for forty-eight hours before entering the hospital. At laparotomy, an 8-cm laceration was found in the dome of the bladder. This was closed after the method to be described shortly and the bladder was drained by means of a urethral catheter. The patient made an uneventful recovery, and when last seen six months after operation he was voiding normally and without residual urine. Cystoscopy at this time showed a perfectly normal bladder mucosa except for the barely perceptible scar at the site of closure.

Two cases of this series showed definite disease of the bladder. In one the bladder wall was infected to the extent that it was described as being phlegmonous. In the other rupture occurred through a diverticulum of the bladder wall.

Table 1 *Etiology of 22 Cases of Intraperitoneal Rupture of the Urinary Bladder*

Disease of bladder wall		
diverticulum	1	
phlegmon	1	
Totals	22	7

Table 1 summarizes the etiologic factors responsible for rupture of the bladder in the 22 cases in this series.

PATHOLOGY

In the majority of cases the actual dissolution of continuity of the bladder wall is represented by a linear tear which, even with the bladder in the contracted state, is usually 5 cm or more in length. The laceration, in the majority of cases runs from a point on one side or the other of the posterior wall, obliquely across the dome to the anterior portion of the opposite side. Because of this antero-posterior direction, it is often difficult to effect adequate surgical closure of the posterior extremity of the laceration.

In an effort to determine the mechanism of rupture of the bladder, Besley⁵ injected fluid into the bladders of 6 cadavers, to the point where the bladder wall ruptured. From these experiments he concluded as follows: (1) There is no constant relative order of tearing of the coats of the bladder. (2) When pressure is applied evenly throughout the bladder the wall ruptures at the weakest point, which is not always the same, anatomically speaking, thus, in 5 of the experiments an intraperitoneal rupture was produced, while an extraperitoneal rupture occurred in the sixth case. (3) In no case did the bladder rest against the promontory of the sacrum, so that this bony projection has nothing to do with the mechanism of rupture.

The sudden expulsion of the contents of the bladder into the peritoneal cavity represents a shock which is tolerated surprisingly well. It is not unusual to find cases reported in which recovery has ensued when surgery has not been resorted to until forty-eight to sixty hours after rupture. Indeed, Quick³¹ reported recovery in a case operated upon ten days and fourteen hours after rupture.

The urine itself is irritating to the peritoneum, and sets up a chemical peritonitis which is similar to that following perforation of a peptic ulcer. If the urine is bacteriologically sterile, this chemical insult is well tolerated. However, if the urine is

INTRAPERITONEAL RUPTURE OF THE URINARY BLADDER

EUGENE A. GASTON, M.D. *

FRAMINGHAM, MASSACHUSETTS

WITH the present-day incidence of automobile and industrial accidents the therapeutic problems incident to trauma to the urinary bladder are becoming increasingly impressed upon the conscience of the profession. Of all the conditions resulting from trauma to the genitourinary organs, intraperitoneal rupture of the bladder is one of the least common, a fact which is adequately explained by the protection afforded by the bony pelvis. Nonetheless, it occurs with sufficient frequency so that all should be familiar with its clinical picture and the therapeutic problems involved, for it presents an emergency that demands immediate surgery if the patient is to survive.

In an effort to evaluate and co-ordinate some of the numerous published opinions as to diagnosis and treatment of this condition, a study was conducted of 22 cases proved at operation or autopsy at the Boston City Hospital during the past twenty years. During the same period 19 cases of extraperitoneal rupture of the bladder have been operated upon. In addition there have been a great many cases of suspected intraperitoneal or extraperitoneal rupture in which, for one reason or another, the exact diagnoses have not been definitely established. These cases have been excluded, with the result that the series is smaller than is desirable for statistical analysis, yet has the great advantage that there can be no doubt as to the exact diagnosis in each individual case.

HISTORICAL

Homer^{10, 20} is credited with having mentioned wounds of the bladder causing death, while Hippocrates stated that such wounds were invariably fatal. For many centuries there was little reason to doubt the accuracy of the latter observation, for in 1882 Rivington²² stated that he doubted whether there had ever been an unequivocal recovery following intraperitoneal rupture. He added that "I do not, in this age of antiseptics, absolutely despair of a time arriving when such can no longer be said." Bell, in 1789, is credited with first having proposed suture of the ruptured bladder, while Grandchamps,¹⁷ in 1826 concluded from animal experiments that the bladder wall could be closed by suture of the muscular and serous coats. By 1888, Grant¹⁸ was able to collect 14 cases of intra-

peritoneal rupture from the literature, all treated by operation. Of these 14 cases there were 5 recoveries and 9 deaths. Since that time there has been an increasing number of case reports, but with few efforts at critical evaluation of the several methods of surgical therapy.

AGE AND SEX INCIDENCE

Intraperitoneal rupture of the urinary bladder can occur in either sex and at any age. Evidence for this statement is found in the present series, which includes a girl of three and a man of seventy-four. As would be expected, however, men between twenty and forty are most frequently afflicted, since they are more exposed to the dangers of trauma and alcoholism. In the series herewith presented there were 16 men and 6 women, a ratio of 3:1. The average age was forty-one years, the male patients averaging forty-five, and the female thirty-two.

ETIOLOGY

Trauma is by far the most frequently encountered etiologic agent in intraperitoneal rupture. The traumatizing force is usually applied directly to the abdominal wall in a person who at the moment has a distended bladder. Since it takes at least 350 cc of fluid to bring the dome of the bladder above the brim of the pelvis, and since this amount of urine is not comfortably tolerated by the normal adult, it is not surprising to find that alcoholism, which not only dulls the sensorium but also causes an increase in urinary output, is very frequently encountered. Of the 22 cases in this series 12 (55 per cent) gave a history of direct trauma to the abdomen (usually a kick in the abdomen, a fall on the abdomen or being crushed between moving objects). Of the 12 cases in which trauma was a major etiologic agent, 5 were in addition alcoholic at the time of rupture. In 2 cases of alcoholism associated with intraperitoneal rupture, no history of trauma could be obtained. This supposed absence of trauma, of course, is open to question. However, in one of these cases the patient was awakened from a drunken stupor by the sudden onset of agonizing abdominal pain, the cause for which was later found to be an intraperitoneal rupture of the bladder.

Intraperitoneal rupture is an occasional complication of the second stage of labor, as was the case

From the Fourth Surgical (Boston University Teaching) Service of the Boston City Hospital.

Formerly resident surgeon, Fourth Surgical Service, Boston City Hospital; now surgeon, Framingham Union Hospital, Framingham, Massachusetts.

cause of a valve-like action, the return flow is impeded. The injection test gave positive information in only 4 cases of this series.

The results of simple catheterization may at times give information which is very misleading, as evidenced by Case 22 of this series. The patient was admitted with a history of symptoms of peritonitis with a total anuria of thirty-six hours' duration. On admission, a catheter was passed into the bladder, yielding 60 cc of clear, yellow urine. An hour later a catheter was again passed and yielded 2000 cc of grossly bloody urine. At operation an 8-cm laceration was found extending across the dome of the bladder in an antero-posterior direction. It is evident that at the first catheterization the catheter was introduced into the bladder, which contained a small amount of grossly normal urine. At the second catheterization it was introduced through the rent into the peritoneal cavity, yielding a large quantity of bloody urine which had been intermittently escaping from the bladder since the rupture had occurred.

Keen²⁴ in 1890 suggested the injection of filtered air into the bladder as an aid in diagnosing intraperitoneal rupture. He pointed out that if rupture were present the injected air would escape into the peritoneal cavity and distend the entire abdomen, whereas if it were not present the resulting area of tympany would be confined to the hypogastric area. Walsham is credited by Besley²⁵ as being the first to apply this test clinically, in 1895. Alexander,¹ in 1901, warned against the massive injection of air, stating that if an intraperitoneal rupture were present the inflation of the peritoneal cavity might lead to a fatal syncope. More recently, Vaughan and Rudnick³⁰ have suggested the injection of a small quantity of air (50 to 100 cc.) If intraperitoneal rupture is present a roentgenogram of the abdomen taken with the patient in the upright position will reveal air between the liver and diaphragm, while if an extraperitoneal rupture is present the air will escape into the fascial planes of the abdomen and thighs, where it will be readily visible in the x-ray picture. We have had no experience with either of the air injection tests, but the feasibility of Vaughan and Rudnick's suggestion can hardly be doubted.

Cystoscopy cannot be recommended as a diagnostic aid in the presence of intraperitoneal rupture of the bladder, since at best it is time-consuming and an ordeal for a patient who is already seriously ill. In the occasional case in which the diagnosis is obscure and the rent in the bladder is small or incomplete, cystoscopy may prove to be of value.

TREATMENT AND MORTALITY

As in the case of rupture of any abdominal viscus, the treatment of intraperitoneal rupture of the urinary bladder is purely surgical. In this series there are 3 cases in which no treatment was instituted and which ended fatally. In each case the clinical diagnosis was missed and the condition was discovered only at autopsy. It is probably correct to state that untreated intraperitoneal rupture of the urinary bladder is invariably fatal.

In reviewing the literature relative to intraperitoneal rupture of the bladder, one is astounded at the lack of agreement among authors as to what actually constitutes adequate surgical treatment. For treatment of the actual laceration, most authors have recommended a double row of inverting sutures of catgut. Crosbie¹² and Dixon and Strohl¹³ have, on the other hand, recommended adequate suprapubic drainage of the bladder with no attempt to suture the laceration. Each author reports successfully treated cases. As to whether or not to drain the peritoneal cavity, opinion is similarly divided. In the majority of cases reported a drain has been placed in the posterior cul-de-sac. Cave¹¹ states, however, that "unless there is present a localized peritonitis with abscess formation, drains placed into the peritoneal cavity are of questionable value." O'Neil³⁰ advocates sewing the cavity up tightly without drainage. Smith³⁶ has recently reported a case in which, after careful suture of the bladder, the peritoneum was closed without drainage with good result. Nicolaysen²⁹ reports 1 case treated successfully by urethral catheter drainage alone.

The question of how best to drain urine from the bladder postoperatively is also a mooted one. MacCormac²⁶ reported recovery in 2 cases in which no provision was made for the escape of urine other than by encouraging the patients to void at frequent intervals. Grant²⁸ recommended emptying by means of repeated urethral catheterizations. He believed that even this precaution might be omitted after four days. Campbell⁹ and others^{16, 38} have stressed the importance of liberal suprapubic drainage. However, many successful cases have been reported in which urethral catheter drainage has proved to be entirely adequate.

In an effort to evaluate the relative accuracy of these conflicting opinions, the present series was subdivided according to whether the bladder wall was sutured, whether bladder drainage was instituted, and if so the type of drainage, and finally whether the peritoneal cavity was drained. Vari-

infected, as is frequently the case in the presence of chronic bladder-neck obstruction from any cause, the immediate chemical insult to the peritoneum sets the stage for the subsequent growth of bacteria from the infected urine. A septic peritonitis which carries a high mortality results. Because low-grade urinary infection is frequently present in persons in the older age groups, it is evident that early operation affords the best protection against the dissemination and growth of bacteria in the peritoneal cavity.

As bladder rupture is most frequently the result of trauma, it is to be expected that in many cases associated injuries will be present to complicate the clinical picture. Of the 14 cases in this series in which rupture was due to trauma, 8 showed no other demonstrable injury of clinical significance. Four patients suffered from fracture of the pelvis, of which 1 had in addition a rupture of the sigmoid flexure of the colon. A fifth had a fracture of the os calcis, and a sixth had a compression fracture of the cervical spine.

Campbell⁹ reports that of 166 cases of fracture of the pelvis seen at the Bellevue Hospital, 15 per cent had also a rupture of the urinary bladder, either intraperitoneal or extraperitoneal. On the other hand, 20 per cent of 55 cases of rupture of the bladder, both intraperitoneal and extraperitoneal, had in addition a fracture of the pelvis.

As mentioned under the discussion of etiology, associated genitourinary disease is occasionally present, and more rarely is responsible for the rupture. In this series is reported 1 case of cystitis and diverticulitis, 1 case diagnosed clinically as phlegmon of the bladder, and 2 cases of bladder-neck obstruction, 1 a postprostatectomy stricture and the other a benign hyperplasia of the prostate.

CLINICAL PICTURE AND DIAGNOSIS

The clinical picture of intraperitoneal rupture of the urinary bladder is frequently misleading. The usual picture is one of an acute abdominal catastrophe following immediately, or soon after, a definite trauma to the abdomen. The patient complains of abdominal pain and, very often, marked frequency and urgency of urination, occasionally of anuria. Examination reveals signs of a rapidly progressive peritonitis, with board-like rigidity of the abdominal muscles and generalized tenderness and rebound tenderness. A boggy induration in the posterior cul-de-sac can occasionally be made out on rectal or vaginal examination. The majority of cases give a history of gross hematuria which, in conjunction with the complaint of frequency and strangury, usually points to the genitourinary apparatus as the site of injury. In 21

cases of this series a definite statement concerning the presence or absence of hematuria was noted. Of these, hematuria was present in 13 (62 per cent).

In cases where rupture occurs without trauma, of which there were 5 in this series (including 2 due to disease of the bladder wall), the clinical picture is much the same, although because of its rarity the diagnosis is frequently obscured since the physician does not consider the urinary bladder in association with the sudden onset of peritonitis. In these 5 cases, 3 patients were awakened by the sudden onset of abdominal pain. In the fourth case, rupture occurred while the patient was under observation in the hospital preparatory to an operation for hydrocele. In the fifth the patient was very sick with pneumonia and died without recognizable abdominal symptoms, and intraperitoneal bladder rupture was not suspected until found at autopsy.

Since a history of trauma may or may not be present, the condition must be differentiated from other and commoner causes of generalized peritonitis of acute onset. These include perforation of a peptic ulcer, acute fulminating appendicitis, ruptured ectopic pregnancy, and so forth. In addition, because of the frequency of alcoholism in these patients, acute alcoholic gastritis with its frequently confusing clinical picture must be ruled out.

To aid in the differential diagnosis, in addition to the very important finding of blood in the urine, we have several clinical tests which may at times prove of great diagnostic importance. The first of these is the well-known, but often misleading, injection test, which consists of injecting through a catheter a known amount of sterile fluid into the previously emptied bladder and noting the amount expelled. If the quantity returned is appreciably less than the quantity injected, this fact supports the diagnosis of intraperitoneal rupture. However, the result of this test depends to a great extent on the type and degree of laceration, and a negative result (that is, fluid expelled equals fluid injected) is without significance. This is readily explained, since if the laceration is small only a minor amount of fluid will escape into the peritoneal cavity, and the quantity returned will so nearly equal the quantity injected that the difference will not be readily measurable. On the other hand, if the laceration is large and open, allowing a free interchange of fluid between bladder and peritoneal cavity, the injected fluid entering by way of the bladder will be returned by the same route and again the quantities of injected and returned fluid will be approximately equal. Thus, the only case in which the injection test will be positive is that where fluid injected into the bladder has free access into the peritoneal cavity but, be

cause of a valve-like action, the return flow is impeded. The injection test gave positive information in only 4 cases of this series.

The results of simple catheterization may at times give information which is very misleading, as evidenced by Case 22 of this series. The patient was admitted with a history of symptoms of peritonitis with a total anuria of thirty-six hours' duration. On admission, a catheter was passed into the bladder, yielding 60 cc of clear, yellow urine. An hour later a catheter was again passed and yielded 2000 cc of grossly bloody urine. At operation an 8-cm laceration was found extending across the dome of the bladder in an antero-posterior direction. It is evident that at the first catheterization the catheter was introduced into the bladder, which contained a small amount of grossly normal urine. At the second catheterization it was introduced through the rent into the peritoneal cavity, yielding a large quantity of bloody urine which had been intermittently escaping from the bladder since the rupture had occurred.

Keen²⁴ in 1890 suggested the injection of filtered air into the bladder as an aid in diagnosing intraperitoneal rupture. He pointed out that if rupture were present the injected air would escape into the peritoneal cavity and distend the entire abdomen, whereas if it were not present the resulting area of tympany would be confined to the hypogastric area. Walsham is credited by Besley as being the first to apply this test clinically, in 1895. Alexander,¹ in 1901, warned against the massive injection of air, stating that if an intraperitoneal rupture were present the inflation of the peritoneal cavity might lead to a fatal syncope. More recently, Vaughan and Rudnick³⁸ have suggested the injection of a small quantity of air (50 to 100 cc). If intraperitoneal rupture is present a roentgenogram of the abdomen taken with the patient in the upright position will reveal air between the liver and diaphragm, while if an extraperitoneal rupture is present the air will escape into the fascial planes of the abdomen and thighs, where it will be readily visible in the x-ray picture. We have had no experience with either of the air injection tests, but the feasibility of Vaughan and Rudnick's suggestion can hardly be doubted.

Cystoscopy cannot be recommended as a diagnostic aid in the presence of intraperitoneal rupture of the bladder, since at best it is time-consuming and an ordeal for a patient who is already seriously ill. In the occasional case in which the diagnosis is obscure and the rent in the bladder is small or incomplete, cystoscopy may prove to be of value.

TREATMENT AND MORTALITY

As in the case of rupture of any abdominal viscus, the treatment of intraperitoneal rupture of the urinary bladder is purely surgical. In this series there are 3 cases in which no treatment was instituted and which ended fatally. In each case the clinical diagnosis was missed and the condition was discovered only at autopsy. It is probably correct to state that untreated intraperitoneal rupture of the urinary bladder is invariably fatal.

In reviewing the literature relative to intraperitoneal rupture of the bladder, one is astounded at the lack of agreement among authors as to what actually constitutes adequate surgical treatment. For treatment of the actual laceration, most authors have recommended a double row of inverting sutures of catgut. Crosbie¹² and Dixon and Strohl¹³ have, on the other hand, recommended adequate suprapubic drainage of the bladder with no attempt to suture the laceration. Each author reports successfully treated cases. As to whether or not to drain the peritoneal cavity, opinion is similarly divided. In the majority of cases reported a drain has been placed in the posterior cul-de-sac. Cave¹¹ states, however, that "unless there is present a localized peritonitis with abscess formation, drains placed into the peritoneal cavity are of questionable value." O'Neil³⁰ advocates sewing the cavity up tightly without drainage. Smith³⁶ has recently reported a case in which, after careful suture of the bladder, the peritoneum was closed without drainage with good result. Nicolaysen²⁹ reports 1 case treated successfully by urethral catheter drainage alone.

The question of how best to drain urine from the bladder postoperatively is also a mooted one. MacCormac²⁶ reported recovery in 2 cases in which no provision was made for the escape of urine other than by encouraging the patients to void at frequent intervals. Grant¹⁸ recommended emptying by means of repeated urethral catheterizations. He believed that even this precaution might be omitted after four days. Campbell⁹ and others^{16, 38} have stressed the importance of liberal suprapubic drainage. However, many successful cases have been reported in which urethral catheter drainage has proved to be entirely adequate.

In an effort to evaluate the relative accuracy of these conflicting opinions, the present series was subdivided according to whether the bladder wall was sutured, whether bladder drainage was instituted, and if so the type of drainage, and finally whether the peritoneal cavity was drained. Vari-

ous combinations of these variables are presented in Table 2. The various groups are too small for statistical comparison, yet give a general conception of the types of treatment adopted together with the results obtained.

Table 2 *Summary of Methods of Surgical Treatment*

BLADDER SUTURE	BLADDER DRAINAGE	PERITONEAL DRAINAGE	RECON- STRUCTED	DIED	MORTAL ITY %
Sutured	Suprapubic	Drained	2	1	33.3

Not sutured	None	Drained	0	1	100.0
No treatment			0	3	100.0
Totals			10	12	55.0

In Table 3, a condensation of Table 2, an effort has been made to determine the importance of the several single factors in surgical treatment. From it we may conclude that the single factor of peritoneal drainage is not of statistical importance in this series if the other factors of treatment are disregarded. Ignoring all points in treatment except that of drainage of the bladder, we find that in cases in which urethral catheter drain-

Table 3 *Evaluation of Methods of Treatment*

	TOTAL CASES	DIED	MORTAL ITY %
Peritoneal cavity drained	15	7	47
Peritoneal cavity not drained	4	2	50

Urethral catheter drainage	11	4	36
Both suprapubic and urethral catheter drainage	1	1	100
No bladder drainage	3	2	67
Suprapubic drainage plus peritoneal drain- age with or without suture of bladder	3	1	33
Urethral catheter drainage plus peritoneal drainage with or without suture of bladder	9	3	33

age was used a mortality of 36 per cent ensued. Suprapubic drainage, on the other hand, carried a mortality of 50 per cent, while 2 of 3 cases in which no provision for drainage of the bladder was made died, a mortality of 67 per cent.

Disregarding for the moment the method of dealing with the lacerated bladder wall, we find in cases in which peritoneal drainage was established that suprapubic and urethral catheter drainage carried the same mortality—33 per cent. However, when the lacerated bladder wall was sutured and the peritoneal cavity drained, suprapubic bladder drainage carried no mortality in 2 cases. Under the same circumstances, urethral catheter drainage carried a mortality of 28 per cent in 7 cases (Table 2).

From these considerations it is evident that the

treatment of a given case must be governed by the patient's general condition and the findings at operation. In the first place, the type of bladder drainage used is not important statistically provided it is adequate. This means that it must prevent a head of pressure from forming against the suture line. If it is technically possible to effect a sound closure of the laceration by means of a double layer of inverting sutures in a young individual who gives no history of previous bladder-neck obstruction, then urethral catheter drainage is adequate and has the advantage of a quicker post-operative convalescence, since there will be no delay caused by a slowly closing suprapubic sinus. On the other hand, if any doubt exists as to the efficacy of the suture line, suprapubic drainage is undoubtedly safer and the speed of convalescence is of secondary importance.

Similarly, in the young individual subjected to traumatic rupture of the bladder in whom there is no reason to suspect pre-existing urinary infection, and who is operated upon within a reasonable time after the rupture has occurred, it is probably safe to close the peritoneum without drainage. But in the older patient in whom there is a possibility of urinary infection, or in any patient, young or old, in whom operation is for any reason delayed beyond ten hours, drainage of the posterior cul-de-sac should be instituted in an effort to prevent an infectious peritonitis.

As has been stated above, it has been held that after suprapubic drainage of the bladder suturing of the bladder wall is unnecessary. In this series, 1 patient so treated died, as did another when the tube was sutured into the laceration itself. In this respect we are inclined to agree with Cave,¹¹ who states that "the patient's condition warranting, the expenditure of ten minutes' additional time for repair by suture seems more than worth while."

A further factor of greatest importance in influencing the mortality of intraperitoneal rupture is the time elapsing from injury until surgical treatment is instituted. In Table 4 the 19 surgically treated cases in this series have been divided into groups according to the time between rupture and surgical treatment. While the number in each group is small, the tendency for the mortality to increase directly with the time between injury and operation is probably accurate, and speaks for operation at the earliest possible moment.

The mortality for the series of treated cases was 47.4 per cent, which compares favorably with that reported from other clinics.^{5, 9, 23, 28, 37, 38}

SUMMARY AND CONCLUSIONS

Trauma not infrequently associated with alcoholism is the commonest etiologic agent encountered in intraperitoneal rupture of the bladder.

The laceration of the bladder wall usually runs in an anteroposterior direction across the dome of the bladder. Because of the obstacles to exposure, adequate closure of the posterior extremity of the laceration is often difficult.

A discussion of the special tests whereby the diagnosis of intraperitoneal rupture of the bladder

Table 4 *Mortality According to Time between Rupture and Operation*

ESTIMATED TIME	NO OF CASES	RECOV- ERED	DELD	MORTAL- ITY %
Less than 12 hours	6	4	2	33
12-24 hours	7	4	3	43
24-48 hours	2	1	1	50
48-72 hours	0			
Over 72 hours	4	1	3	75
Totals	19	10	9	47

may be definitely established is presented. Although we have had no experience with the suggestion of Vaughan and Rudnick that air be injected into the bladder, the method seems logical and worthy of trial. In the event of intraperitoneal rupture a roentgenogram of the abdomen taken in the upright position will disclose air in the sub diaphragmatic space.

Treatment of intraperitoneal rupture of the bladder is purely surgical and should encompass three aims, namely the treatment of the laceration of the bladder wall, the treatment of the peritoneum, and the method of establishing adequate drainage of bladder urine. A discussion of these factors and their relative importance is presented.

The mortality is directly proportional to the time elapsing between rupture and the institution of adequate surgical treatment.

ous combinations of these variables are presented in Table 2. The various groups are too small for statistical comparison, yet give a general conception of the types of treatment adopted together with the results obtained.

Table 2 Summary of Methods of Surgical Treatment

BLADDER SUTURE	BLADDER DRAINAGE	PERITONEAL DRAINAGE	RECOV- ERED	DIED	MORTAL- ITY %
Sutured	Suprapubic	Drained	2	1	33.3
Sutured	None	None	1	0	—
Sutured	None	Drained	5	2	28.0
Sutured	Urethral	None	1	1	50.0
Not sutured	Urethral	Drained	1	2	66.6
Sutured	Suprapubic	None	0	1	100.0
Sutured around suprapubic drain	Suprapubic and Urethral	Drained	0	1	100.0
Not sutured	None	Drained	0	1	100.0
No treatment			0	3	100.0
Totals			10	12	55.0

In Table 3, a condensation of Table 2, an effort has been made to determine the importance of the several single factors in surgical treatment. From it we may conclude that the single factor of peritoneal drainage is not of statistical importance in this series if the other factors of treatment are disregarded. Ignoring all points in treatment except that of drainage of the bladder, we find that in cases in which urethral catheter drain-

Table 3 Evaluation of Methods of Treatment

	TOTAL CASES	DIED	MORTAL- ITY %
Peritoneal cavity drained	15	7	47
Peritoneal cavity not drained	4	2	50

Urethral catheter drainage	11	4	36
Both suprapubic and urethral catheter drainage	1	1	100
No bladder drainage	3	2	67
Suprapubic drainage plus peritoneal drain- age with or without suture of bladder	3	1	33
Urethral catheter drainage plus peritoneal drainage with or without suture of bladder	9	3	33

age was used a mortality of 36 per cent ensued. Suprapubic drainage, on the other hand, carried a mortality of 50 per cent, while 2 of 3 cases in which no provision for drainage of the bladder was made died, a mortality of 67 per cent.

Disregarding for the moment the method of dealing with the lacerated bladder wall, we find in cases in which peritoneal drainage was established that suprapubic and urethral catheter drainage carried the same mortality—33 per cent. However, when the lacerated bladder wall was sutured and the peritoneal cavity drained, suprapubic bladder drainage carried no mortality in 2 cases. Under the same circumstances, urethral catheter drainage carried a mortality of 28 per cent in 7 cases (Table 2).

From these considerations it is evident that the

treatment of a given case must be governed by the patient's general condition and the findings at operation. In the first place, the type of bladder drainage used is not important statistically provided it is adequate. This means that it must prevent a head of pressure from forming against the suture line. If it is technically possible to effect a sound closure of the laceration by means of a double layer of inverting sutures in a young individual who gives no history of previous bladder-neck obstruction, then urethral catheter drainage is adequate and has the advantage of a quicker post-operative convalescence, since there will be no delay caused by a slowly closing suprapubic sinus. On the other hand, if any doubt exists as to the efficacy of the suture line, suprapubic drainage is undoubtedly safer and the speed of convalescence is of secondary importance.

Similarly, in the young individual subjected to traumatic rupture of the bladder in whom there is no reason to suspect pre-existing urinary infection, and who is operated upon within a reasonable time after the rupture has occurred, it is probably safe to close the peritoneum without drainage. But in the older patient in whom there is a possibility of urinary infection, or in any patient, young or old, in whom operation is for any reason delayed beyond ten hours, drainage of the posterior cul-de-sac should be instituted in an effort to prevent an infectious peritonitis.

As has been stated above, it has been held that after suprapubic drainage of the bladder suturing of the bladder wall is unnecessary. In this series, 1 patient so treated died, as did another when the tube was sutured into the laceration itself. In this respect we are inclined to agree with Cave,¹¹ who states that "the patient's condition warranting, the expenditure of ten minutes' additional time for repair by suture seems more than worth while."

A further factor of greatest importance in influencing the mortality of intraperitoneal rupture is the time elapsing from injury until surgical treatment is instituted. In Table 4 the 19 surgically treated cases in this series have been divided into groups according to the time between rupture and surgical treatment. While the number in each group is small, the tendency for the mortality to increase directly with the time between injury and operation is probably accurate, and speaks for operation at the earliest possible moment.

The mortality for the series of treated cases was 47.4 per cent, which compares favorably with that reported from other clinics.^{5, 9, 23, 28, 37, 38}

SUMMARY AND CONCLUSIONS

Trauma not infrequently associated with alcoholism is the commonest etiologic agent encountered in intraperitoneal rupture of the bladder.

The laceration of the bladder wall usually runs in an anteroposterior direction across the dome of the bladder. Because of the obstacles to exposure, adequate closure of the posterior extremity of the laceration is often difficult.

A discussion of the special tests whereby the diagnosis of intraperitoneal rupture of the bladder

Table 4 Mortality According to Time between Rupture and Operation

ESTIMATED TIME	NO OF RECENT CASES	DECEASED	DIED	MAY BE LIVED
Less than 12 hours	6	4	2	33
12-24 hours	7	4	3	43
24-48 hours	2	1	1	50
48-72 hours	0			
Over 72 hours	4	1	3	75
Totals	19	10	9	47

may be definitely established is presented. Although we have had no experience with the suggestion of Vaughan and Rudnick that air be injected into the bladder, the method seems logical and worthy of trial. In the event of intraperitoneal rupture a roentgenogram of the abdomen taken in the upright position will disclose air in the subdiaphragmatic space.

Treatment of intraperitoneal rupture of the bladder is purely surgical and should encompass three aims, namely, the treatment of the laceration of the bladder wall, the treatment of the peritoneum, and the method of establishing adequate drainage of bladder urine. A discussion of these factors and their relative importance is presented.

The mortality is directly proportional to the time elapsing between rupture and the institution of adequate surgical treatment.

RECENT PROGRESS IN PHYSIOLOGY

HEBBEL E. HOFF*

NEW HAVEN, CONNECTICUT

"WE seek truth itself," wrote Claude Bernard¹ in *La Science Expérimentale*, "and if we continue ever to seek it, it is because the part of it that we have already found does not satisfy us" Priestley² also recognized that the scientist's search for truth yielded only fragments, some of them important, and all making up the general body of fact constituting a science when he wrote

In completing one discovery we never fail to get an imperfect knowledge of others, of which we could have no idea before, so that we cannot solve one doubt without creating several new ones

Travelling on this ground resembles Pope's description of travelling among the Alps, with this difference, that here there is not only a *succession*, but an *increase* of new objects and new difficulties

So pleas'd at first the tow'ring Alps we try,
Mount o'er the vales, and seem to tread the sky
Th' eternal snows appear already past,
And the first clouds and mountains seem the last.
But those attained, we tremble to survey
The growing labours of the lengthen'd way
Th' increasing prospect tires our wand'ring eyes,
Hills peep o'er hills, and Alps on Alps arise."

Difficulties of perspective must always concern him who attempts to write on progress in physiology rather than to present a review of the recent literature. Discoveries which seem of the greatest importance when first announced may later be found to be mere foothills hiding from sight a great peak. So also a great discovery, seen unclearly, may appear as an insignificant landmark until great effort and years of progress reveal it in its true stature. The history of physiology is replete with examples of this kind. The discovery of ganglia in the heart by Remak,³ once hailed as the final proof of the neurogenic theory of the heart beat, is the classic example of the first type, while Purkinje's discovery⁴ of the peculiar fibers along the inner walls of the chambers of the heart shows what great importance may some day be attributed to a long-neglected observation.

If one can at all distinguish the contributions in physiology in the past years, it is in the brilliant application of Claude Bernard's insistence on the essential unity of phenomena in living and non-living systems, and the necessity of studying them by the same methods. It will be recognized from

what follows how greatly the physiologist is indebted to the chemist, and especially the physicist, who thus repays the physiologist for teaching him how to make electricity by the union of two dissimilar metals.

THE PHYSIOLOGY OF NERVE AND MUSCLE

Muscular Contractions

Few aspects of physiology have been studied as long or as fruitlessly as that which relates to the intimate nature of muscular contraction. The last few years, however, have seen the development of a method that holds great promise for the future of this subject, namely the method of x-ray diffraction so ably employed by Astbury and his co-workers.⁵⁻¹² Their work is based primarily on earlier demonstrations by the same technic as that which shows that silk fibers are made up of bundles of protein molecules composed of alternate molecules of alanine and glycine in the classic polypeptide linkage of Fischer. From a stereochemical viewpoint, these molecules were shown to be fully extended, and thus incapable of elongation and elastic recoil. The molecules composing hair or other keratin structures, which are known to be elastic over a wide range, were then demonstrated to exist normally in a state of partial contraction owing to the formation of temporary ring structures, probably as a result of attraction between the side chains. When stretched to the limit, these molecules assume a fully extended structure in every way similar to the natural state of silk molecules. Next, it was shown that under the influence of initial stretch plus steam, the normally partially contracted molecules of hair would pass into a still shorter or supercontracted state, again by the formation of further ring structures.

These observations upon keratin were then extended to dried films of the muscle protein myosin, which showed an identical behavior. Such films normally exist in the partially contracted or α keratin state, and can be stretched out to the fully extended or β keratin state. Under the influence of steam and initial tension they also pass into a state of supercontraction. Washed and dried muscle of the foot retractor of *Mytilus edulis* has also been demonstrated to be composed of similar longitudinal bundles of polypeptide chains existing in the partially buckled or α keratin state, and capable of being stretched to the fully extended state.

Laboratory of Physiology Yale University School of Medicine New Haven

*Assistant professor of physiology Yale University School of Medicine.

The implication is clear that the contraction of muscle may be due to the actual shortening of the molecules of protein which make up the greater proportion of its substance, corresponding to the supercontraction of protein chains in hair and myosin films. That this is actually the case has not of course been demonstrated as yet, but such an explanation would fit in with many of the known facts of muscle physiology. It would, for instance, explain the well-known effect of increased initial tension in promoting vigorous contraction, which finds such striking application in Starling's law of the heart. Bernal¹³ has recently shown how the cross-striations seen in many types of muscle may be accounted for by the twisting of such long molecules along the longitudinal axis of the muscle fiber, an idea also suggested by Tiesgs,¹⁴ and it is not improbable that the change in the cross-striations during muscular contraction is due to a different degree of twisting, associated with a more acutely buckled molecule. The work of Bernal also indicates how ionic changes produced by electrical stimulation or by the action of large positively charged ions such as potassium may bring about shortening of unstable molecules, while such ions as calcium may exercise a stabilizing influence.

*The Compound Nature of the Action Potential and the Reaction to Subthreshold*Stimulation*

The classical researches of Erlanger and Gasser have led to so many basic advances in physiological thinking that to attempt any sort of comparative evaluation is futile. There are two recent developments,^{15, 16} however, which seem to hold infinite promise. The first of these is the elucidation of the compound nature of the monophasic action potential and the association of coincident changes in threshold with its various parts. It is now recognized that the single monophasic action potential is made up of at least four parts: (1) the spike, a brief period of negativity associated with the local discharge of the propagated disturbance, followed by (2) a brief positive afterpotential not always found, (3) a somewhat longer negative afterpotential, and (4) a much longer positive afterpotential. A great many procedures have been employed to demonstrate that these four parts are actually separate processes capable of independent variations.

These portions of the electrical disturbance following discharge of the impulse in an excitable tissue have next been correlated with changes in threshold. It is known that the duration of the spike coincides with the absolutely refractory period, the first positive afterpotential with the relative refractory period, the negative afterpotential with the supernormal period, and the second pos-

itive afterpotential with a prolonged period of relative inexcitability. Thus the classic picture of the threshold changes following a propagated disturbance is enlarged to include a final, fairly prolonged period of heightened threshold of which physiologists had been unaware, and the relation of these changes to alterations in potential is demonstrated.

The applications of these discoveries to many fields have already been numerous, but an especially significant one to simple nerve fibers deserves attention. This is the implication of the second positive afterpotential and the negative afterpotential in the production of rhythmic discharge. In conditions in which the supernormal period is not in great evidence, relatively slow rhythms comparable to that of the heart are set up by the application of constant stimuli, in which the limiting factor seems to be the positive afterpotential. Under circumstances in which the supernormal phase is pronounced, more rapid rhythms or tetany are produced in which the limiting factor is the supernormal phase. Thus an adequate explanation is afforded for the old observation of Wedensky,^{17, 18} who noted that in a fatigued muscle-nerve preparation subjected to tetanic stimulation at a level barely below the threshold, application of a single threshold stimulus was followed by a tetanic response which continued as long as the previously subthreshold stimulus was maintained. In the light of the present work it is recognized that the single effective shock produced a discharge, which was followed by a supernormal period during which the previously ineffective stimulus was capable of evoking a second response, and so on.

The second contribution, implied in work extending over a number of years, but only recently clearly stated, is the demonstration that very similar changes both in threshold and potential follow a single stimulus which is ineffective in producing a propagated disturbance.¹⁹ In the chain of events following such a stimulus only the spike of the action potential and the absolutely refractory period are lacking. The first and second positive afterpotential find representation in coincident increases in threshold, and the negative afterpotential is accompanied by a decrease in threshold.

The first positive potential wave and its accompanying relative refractory period find application in explanation of the Gildemeister phenomenon, in which a single ineffective shock applied to a nerve can render ineffective a second shock following closely after it, even though the second shock alone can be demonstrated to be well above threshold strength. The first shock, although ineffective, had obviously left behind a period of relative refractoriness, which rendered ineffective a

previously effective stimulus. In a similar manner the Wedensky inhibition may be explained.

Recognition of the next phase in the cycle of charges of threshold following a subthreshold stimulus permits an insight into an important physiological phenomenon, loosely termed "summation." It has long been known that during the stage of partial curarization of the myoneural junction a single volley arriving over the motor neuron may prove ineffective, while two volleys, even though fairly widely separated, evoke a response in the muscle. A similar phenomenon has been shown to exist in an isolated nerve trunk, usually over a shorter temporal course, although in certain abnormal conditions summation intervals of several hundred milliseconds are discovered. It is clear that the actual stimulus (that is, electrical shock) is of extremely short duration, and at the neuromuscular junction the spike potential of the nerve ending or the quantum of acetylcholine liberated disappear with almost equal rapidity. It is therefore impossible to speak of a temporal summation of subliminal stimuli in any strict sense. Actually, the first subliminal stimulus, although it quickly disappears, evokes a reaction in the stimulated area, producing, after a short, relatively refractory period, a period of enhanced excitability during which the second, normally subthreshold, stimulus is now effective. It may well be that the second stimulus too is ineffective, but it is in turn followed by a somewhat greater depression of threshold during which a third stimulus is capable of initiating a propagated discharge. There can be little doubt that this concept will prove of the greatest value in all applications of what now must appear to be an inappropriate term "temporal summation."

Humoral Transmission at the Myoneural Junction

The third major advance in knowledge of the physiology of nerves and muscles lies in the application to skeletal neuromuscular transmission of a concept previously applied in the autonomic system to account both for transmission at the synapse between preganglionic and postganglionic neurons and the mediation of the action of the postganglionic activity on the effector systems. Sir Henry Dale, who with his co-workers is largely responsible for this newer concept, has called attention to the fact that DuBois-Reymond²⁰ had suggested that nerves may act to stimulate muscles by liberating at their endings in the muscle a quantum of a chemical substance which is the direct stimulator of muscular activity. The various steps in the development of the subject since then have also been traced in recent publications by Sir Henry Dale.²¹ Their culmination in the discovery by Loewi of a chemical transmitter, later shown to be acetylcholine, in parasympathetic ac-

tivity and of a sympathetic transmitter resembling adrenalin by Cannon must be classed with the most important physiological discoveries of the century. More recent have been the postulation of an acetylcholine transmission at the synapses in autonomic ganglia, largely through the work of Dale, and lately the claim has been advanced that at the motor end plate of skeletal muscles an acetylcholine transmission also occurs.²⁻²⁵

Naturally these claims have not met with universal acceptance, and adherents are still to be found to the theory that the spike potential of the nerve ending in the muscle constitutes the stimulus to muscular contraction.²⁶ An examination of material presented on both sides of the controversy reveals that both theories fail to satisfy all the criteria of rigorous proof, of which the following may be mentioned.

Is the theoretical transmitter present at the synapse at the time of transmission? Obviously the spike potential of the nerve ending must be present, although it has of course never been recorded. Acetylcholine can be detected in perfusates, but does not begin to appear for several minutes after stimulation begins. Obviously the perfusion technic cannot provide the essential proof of accurate time relations. It fails to prove that the material recovered actually originates in the synapse, and Lorente de N6²⁷ claims that in fact nonsynaptic tissue gives as much acetylcholine as do synaptic regions. Of course action potentials are also found in synaptic and nonsynaptic regions.

Both acetylcholine and rapid electric shocks—more specifically spike-action potentials—are known to stimulate muscles when properly applied. So, however, do a great many other substances. Potassium ions, which may well play a part in transmission, are particularly excellent stimulators. Evidence that acetylcholine when injected into muscles causes all-or-nothing contractions cannot therefore be considered as more than presumptive evidence, which already exists in equal strength for electrical transmission.

It seems therefore that evidence for chemical transmission can be balanced by equally weighty, yet equally inconclusive, evidence for electrical transmission, and that a decision cannot be made at this time.

Smooth Muscle

Valuable contributions have recently been made to this hitherto neglected field in physiology by the studies of Rosenbluth and collaborators,^{28, 29} by Eccles and a co worker,^{30, 31} and by Fletcher.^{32, 33} Study of their work reveals primarily how little really is known of the physiology of smooth muscle. Save only for the work of McSwiney,³⁴ almost nothing is known of the nature of the sim-

ple muscle twitch of smooth muscle. The identity of the smooth muscle "motor unit" is equally unknown, as are the parts played by contraction of the twitch and tetanus type, and by contracture in producing tension in various smooth muscles. Whether the basic syncytium is of physiological importance and how far it accounts for co-ordination of contraction are subjects only for conjecture. What is more surprising, it is impossible to find agreement concerning the presence of a spike action potential characteristic of propagated disturbance in smooth muscle. The well-recognized presence of a spike potential in active cardiac muscle, and the careful analysis of the potential waves found by Eccles, seem to indicate that at least in the smooth muscle which he studied, the retractor muscle of the nictitating membrane, a spike potential exists. Incidentally, Eccles was able to record long-lasting (200-millisecc.) negative potentials in this muscle following subthreshold volleys via its motor nerve, and demonstrated that during this period summation of a second individually inadequate volley was possible. Much basic work on smooth muscle will probably follow these very stimulating investigations.

THE CENTRAL NERVOUS SYSTEM

Nature of the Central Processes

Few suggestions have been of more value to physiologists than Keith Lucas's³⁷ to the effect that phenomena in the central nervous system are susceptible of explanation in terms of events in simple nerve and muscle. Today, with rival theories of neuromuscular transmission dividing physiologists into opposing camps, the genius of Lucas is more than ever needed to point the path to those who venture into the central nervous system. The evidence which Dale and his collaborators have accumulated in favor of synaptic transmission has been largely concerned with the transneuronal transmission in sympathetic ganglia, in which but a single synapse is involved, but which shows many of the characteristics of transmission within the spinal cord. These workers have carefully avoided any attempts to extend their theory to the central nervous system, in the absence of strict proof. Recently Wright and others³⁸⁻³⁹ have clearly shown that acetylcholine, eserine and adrenalin, all implicated in humoral transmission in peripheral structures, have no less striking effects on reflex activity in the cord. They too, however, emphasize that the evidence they present need only indicate a pharmacologic effect having no necessary relation to the normal physiology of reflex activity. The recent paper of Lorente de N6, calling in question the essential evidence upon which Dale's work is based, serves to emphasize

the very tentative state of all theories at present entertained.

The work of Gasser on the excitability changes following propagated discharges and subliminal stimuli is on the other hand being applied with increasing success to interneuronal transmission. The most profitable application has been the elucidation of the central excitatory state of Sherrington as the period of lowered threshold following a subliminal stimulus, and the central inhibitory state as in all probability a manifestation of the period of increased threshold following a subliminal stimulus. The independent work of Eccles³⁹ and Lorente de N6⁴⁰ indicates that in the central nervous system a distinction between "temporal" and "spatial" summation must be made, as it can be in peripheral nerves. Thus the effects of a simultaneous discharge of several "boutons" or synaptic endings is brought about by a true "spatial" summation of the stimulus produced by each, whether electrical or chemical. Repeated volleys over the same endings must, however, be separated by an interval no less than the absolutely refractory period of the ending, with the result that the voltage of the spike, or the quantum of acetylcholine, has disappeared by the time the second stimulus arrives. In such circumstances the resulting discharge is in reality brought about by the lowering of threshold which invariably follows a subliminal stimulus.

Application of the study of action potentials to the central nervous system presents difficulties identical with those faced by earlier electrocardiographers, amplified many fold: (1) the necessity for indirect leads, (2) a complicated system of action potential production, and (3) the serving of only a small proportion of the cells as a pacemaker, with functional communications on a wide scale. For this reason the analysis of electrical charges in the central nervous system is still incomplete. Those of the spinal cord are naturally more simple but even they present great difficulties. Even so, the presence in cord potentials of the usual spike and afterpotentials are to be recognized, and the association with them of threshold changes is determined.

The analysis of brain potentials by Davis and his collaborators in Boston⁴¹ and by Adrian⁴² in England has served to introduce a subject which still remains in great confusion. The recent authoritative review by Jasper⁴³ should also be consulted.

Central Representation of the Autonomic System

The original hypothesis as proposed by Bichat to account for the activity of the autonomic nervous system attributed to that system complete independ-

ence of the central nervous system, and located the source of spontaneous activity and the center for reflex behavior in the peripherally situated ganglia. While some modern work, notably that of Schwartz,⁴⁴ suggests that reflexes may possibly take place in ganglia isolated from the central nervous system, the bulk of evidence suggests most strongly that representation of the autonomic system is to be found side by side with that of the skeletal nervous system at each level of integration. Spinal autonomic reflexes have in fact been reported, and the decerebrate animal possesses many notable autonomic reflexes. Further representation in the hypothalamus has been recognized for a number of years, and Ranson's⁴⁵ Harvey Lecture for 1937 summarizes this subject from the viewpoint of one of its most active students.

It is no less certain that the autonomic system is well provided with cortical representation. The recent review by Fulton⁴⁶ indicates that cortical representation had in fact been suspected by a great number of the best neurologists of the nineteenth century, but the experiments which they carried out failed to meet all the criteria of rigorous proof. Within the past few months definite, unequivocal evidence of cortical representation has been provided by the work of E. C. Hoff and Green.^{47, 48} Rigorously excluding changes produced by spread of current and due to reflexes originating in the movements of skeletal muscle, these investigators were able to demonstrate the presence of sharply circumscribed areas whose stimulation produced changes in blood pressure, heart rate and capacity of the vascular bed in the kidney and leg. Both the motor and premotor areas contained motor point, and very closely located spots often gave diametrically opposed results. Rioch and his co-workers⁴⁹ and Schwartz⁵⁰ furnish corroborative evidence. Further evidence of the close functional interrelation between the centers of autonomic and skeletal reflexes is provided by the observations of Dusser de Barenne and Ward,⁵¹ Schweitzer and Wright,⁵² and Barclay and Franklin,⁵³ who independently demonstrated the effect of somatic reflexes of afferent stimulation normally associated with autonomic reflexes. The postural changes associated with micturition in animals are of course obvious examples of this close interaction.

THE CARDIOVASCULAR SYSTEM

Intraventricular Conduction

For years the classic description by Lewis of the spread of the cardiac impulse through the ventricles has taught that the impulse is propagated at a rapid rate in the bundle of His and Purkinje fibers to the endocardial surface of the ventricles,

where a transition to muscle fibers takes place and a much slower conduction outward to the epicardial surface occurs.

Objections to this hypothesis were first raised by Robb⁵⁴ in her careful anatomical studies of the distinct muscle bundles of which the heart is composed. She suggested that just as each bundle has its own blood supply, and suffers as a unit from obstruction to that supply, so also it is activated by its own Purkinje supply. The spread of the cardiac impulse must therefore be considered to consist of a rapid spread along the Purkinje system to a muscle bundle, and from there along the bundle by direct conduction along muscle fibers, as in the auricle, at a rate not much less than that in the Purkinje system.

Somewhat later, several workers found unmistakable proof that the Purkinje system extended beyond the subendocardial network, throughout the entire myocardium.^{55, 56} This extension of the Purkinje system, which in fact had not entirely escaped the notice of earlier histologists, provided the incentive to a renewed study of the spread of the impulse through the ventricle, with the use of more adequate recording systems, and avoidance of cooling and drying of the surface of the heart. These studies^{57, 58} have shown fairly conclusively that the impulse does arrive first at the septum, and the region of the ventricular walls near the septum, as demonstrated by Lewis. It is obvious also that the entire heart, both internally and externally, is then activated very rapidly, and that no differences can be found between the inside and outside. Finally, no evidence can be found to support Robb's suggestion that the process of excitation follows muscle bundles. It can thus be concluded that the intramuscular Purkinje network acts to distribute the cardiac impulse, with great rapidity, to all parts of the myocardium, rather than to the endocardial surface of the ventricles, as was formerly believed.

The Blood Supply of the Myocardium

A second fundamental contribution to the knowledge of the heart is recognized in the studies of Wiggers and his associates on the blood supply of the myocardium. Recent anatomical investigations, well reviewed by Wearn in Levy's *Diseases of the Coronary Arteries and Cardiac Pain*,⁵⁹ have indicated that blood entering the coronary arterioles may take widely differing courses to the right ventricle. Some, of course, may pass into capillaries and thence by way of the venules into the coronary sinus and right auricle. The well-known Thebesian channels may divert some blood from the capillaries and venules directly into the right ven-

tricle. It is now recognized that accessory passages, the arteriosinuosidal and arteriololuminal vessels, also exist between the arterioles and the ventricular chambers

Some of the physiological implications of these facts have been recognized for many years, and while it is known that under certain conditions approximately 70 per cent of the coronary flow returns through the coronary sinus, physiologists have found that the actual proportions may vary widely. In fibrillating hearts especially, the Thebesian outflow was found to predominate. This led to the supposition, now carefully worked out by Johnson and Wiggers,⁶⁰ that right ventricular pressure is a major factor in diverting blood from the Thebesian channels to the coronary sinus. Johnson and Wiggers now report the following important conclusions: (1) the coronary sinus normally empties into the right atrium only during systole, (2) increasing the right ventricular pressure causes a proportional increase in coronary sinus outflow, all other factors remaining constant, and (3) the increase in coronary sinus outflow produced by certain drugs and by stimulation of cardiac nerves may well be the result of slight elevation of right ventricular pressure. It is more than ever obvious, therefore, that the measurement of coronary sinus outflow, taken by itself, cannot be used as a method for estimating the amount of coronary circulation or the variations it may undergo.

To the question of how coronary flow may be measured, Johnson and Wiggers⁶⁰ have devoted great perseverance and the most exquisite techniques. The present studies, well reviewed in the chapter on coronary flow written by Wiggers for Levy's *Diseases of the Coronary Arteries and Cardiac Pain*,⁵⁹ are based principally upon the determination of the velocity of blood flow by the method of Pitot's tubes, in which the velocity is calculated from the differential pressure between two tubes inserted into a vessel, one directed against and one with the circulation. The most interesting outcome of this method to date is the confirmation of the finding of Anrep that the flow of blood may slow or even stop momentarily during the brief isometric phase of systole, coupled with the demonstration that despite this momentary stoppage, as much or more blood may flow out of the coronaries during systole as during diastole.⁶¹

The Action Potentials of the Myocardium

The identification of the multiple phases of the monophasic action potential in nerve fibers carries with it the important implication of application to other tissue producing action potentials.

Of all such tissues perhaps the heart is most interesting, and presents the most difficulties. Much remains to be learned: the nature of the monophasic action potential has become the subject of renewed study,^{62 63 64} and the manner in which local potentials summate to produce the electrocardiogram as derived from external leads continues to be debated.^{62 64 65}

Especially interesting have been the successful attempts of Rothberger and Goldenberg⁶⁶⁻⁷⁰ to register monophasic action potentials from isolated strips of Purkinje fibers. These strips, which beat rhythmically, show a monophasic action potential of at least two phases, a spike and a negative afterpotential. Slow changes from positivity to negativity are occasionally detected immediately before the spike of spontaneous discharges.

Simultaneous mechanograms prove definitely that the electrogram does not terminate with the end of mechanical events, but persists for some time after, and varies independently of mechanical events under the influence of a variety of conditions. This suggests that the association of the end of the T wave in the electrocardiogram with the end of systole is neither exact nor of any significance.

These studies have offered a new approach to a problem that has long agitated physiologists: the origin of the so-called "ectopic" arrhythmias, including extrasystoles and tachycardias from both auricles and ventricles. There has been a growing tendency to consider these as the result of "re-entrant excitation" from a wave traveling continually in a circle in the cardiac tissue. While this hypothesis successfully accounts for auricular flutter and fibrillation, its extension to the extrasystolic arrhythmias has been vigorously opposed by those who favor the hypothesis that these irregularities are brought about by the development of an ectopic pacemaker, which gives rise to a single beat, a short burst of tachycardia, or a long run of tachycardia, depending upon the degree to which its rhythmicity surpasses that of the normal pacemaker and the persistence of this change.

In favor of circus movement has hitherto been the phenomenon of "coupled beats" or "bigeminy," in which an extrasystole alternates with a normal beat. It was noticed that the extrasystole was in some way coupled with the preceding beat, if the rhythm of the normal beat was altered, that of the extrasystole likewise changed, and to the same degree. It was thought that the normal beat set up a circus movement in the heart, which after traversing some undesignated pathway emerged to stimulate the heart and provoke the premature beat.

The Viennese workers finding that isolated strips

of Purkinje fibers produced action potentials having many of the characteristics of nerve fibers, recalled that the work of Gasser and Erlanger had solved the mechanism of a phenomenon discovered long before by Wedensky. As mentioned before, this worker had noticed that a frog's motor nerve, on being stimulated tetanically at a sub-threshold level, responded to a single effective shock, not by a single twitch but by a tetanus, which persisted as long as the previously sub-threshold stimulus was maintained. It became obvious that the preparation must have been one showing a marked supernormal phase after recovery from the refractory period of the single shock. During this period the previously ineffective tetanic stimulation evoked a response, likewise followed by a supernormal phase, and so on. It was then found that in isolated Purkinje strips the coupled beat occurred just at the height of the supernormal period following the first beat. This work suggests that just as a marked supernormal period in the nerve is found to favor the appearance of tetanic discharge, so also in the heart a supernormal period forms the basis for the development of ectopic arrhythmias of all types. Certainly these observations convert a cogent reason for believing in the circus movement into very much more valid evidence for the ectopic pacemaker theory. While the importance of these experiments and the inferences to be drawn from them are obvious, the presence of supernormality in the intact mammalian heart remains to be adequately explored. Only then can the significance of the present studies be determined with accuracy.

Physiology of the Veins

Study of the physiology of the veins has received renewed impetus in the publication of Franklin's¹ *Monograph on Veins*. The volume reflects not only the important contributions he has made to the subject through a series of investigations extending over many years, but also a deep interest in the history of the circulation, so well manifested in his translation of Lower's *Treatise on the Heart*. Another individual contribution worthy of note is the demonstration by Nonidez² of the presence of receptor organs in the intrapericardial parts of the great veins. Both the venae cavae as well as the pulmonary veins are shown to be richly supplied with subendothelial endings greatly resembling the pressor-receptors in the carotid sinus, the aorta and the right subclavian artery. Endings of a different type were found around the muscle fibers in the walls of the pulmonary veins and superior vena cava. The first were assumed to be the receptor organs for the reflex first described by Bainbridge, who found that increase in the pressure within the right auricle evoked a reflex ac-

celeration of the heart. No function has been ascribed to the perimuscular terminations.

RESPIRATION AND METABOLISM

Nervous Control of Respiration

The role of the carotid body in the regulation of respiration was anticipated many years ago by Siciliano,³ who occluded the great arteries of the neck and observed both changes in blood pressure and alterations in rate and depth of breathing. He clearly stated his belief that the region of the common carotid near the bifurcation might prove to be an important point of origin for reflexes regulating the blood pressure and respiration. It is only recently, largely through the work of Heymans, that the carotid body has been recognized as a center specifically stimulated by anoxia. The most recent development in this field has been the discovery that certain drugs act to stimulate respiration by virtue of a local action on the carotid body.⁴⁻⁶

The location of the "respiratory center" has interested physiologists ever since Legallois found that damage to the medulla was followed by arrest of respiration. Since then attempts to delimit more exactly the areas involved have employed such methods as local warming and cooling,⁷ application of drugs to discrete areas and the production of small, circumscribed injuries. All these methods have failed to indicate that any specific group of cells in the medulla is the pacemaker of the respiratory center. More recently the method has been introduced of obtaining action potentials through small electrodes inserted into various parts of the medulla.⁷⁻⁹ These have shown that cells in a number of the nuclei of the medulla discharge rhythmically in synchrony with discharge of the motor neurons of the respiratory muscles, and that to none of them can as yet be ascribed the function of pacemaker. Just as the precise location of the pacemaker of the heart depended upon the determination of the point of primary negativity, so it would seem that the position of the respiratory pacemaker depends upon the exact timing of the moment of discharge of one group of cells as compared with the others.

The Intimate Nature of Cell Respiration

Recent years have seen the development of a new approach to the problem of the intimate nature of cell and tissue respiration, namely the development of instantaneous methods of assaying changes in the interior by color or spectroscopic changes. The determination by Keilin in 1925 of the time of reduction of cytochrome is observed visually in a spectroscope was followed by the use of photoelectric cells for study of similar activity in yeast

by Haas in 1934. Optical changes in contracting muscle were recorded photoelectrically by von Muralt in 1934. Last year Millikan⁵⁰ reported the measurement of the reduction of muscle hemoglobin in intact muscles, using a photoelectric cell to pick up changes in color of the muscle illuminated transversely. The system was made stable to a variety of possible variants such as thickness of muscle, amount of contained blood and the changes in opacity noted by von Muralt, by utilizing only the change in transmissibility of green and red light brought about by reducing or oxidizing muscle hemoglobin. Millikan concludes from these experiments (1) muscle hemoglobin acts as a short-time oxygen store to tide the muscle over from one contraction to the next, (2) when contraction takes place the oxygen demand starts to rise in less than 0.2 seconds, reaches its maximum value within 1 second, and falls nearly to its resting value within 10 seconds of the end of the contraction, (3) blood flow through the soleus muscle of a cat appears not to be greatly affected by maximal tetanic contraction, whether the muscle is stimulated directly or by its nerve.

It is too early to attempt to fit information such as this into the general picture of muscle chemistry. It is essential to point out, however, that the accuracy of the time values obtained by such methods is conditioned by the nature of the recording system. The galvanometer used by Millikan to register the changes in current produced by the photoelectric cell was stated to have a period of about one second, a figure out of all proportion to the time relations that undoubtedly occur. This problem has been considered in a second series of experiments designed to answer the question of whether enzymes enter into chemical combination with the substrate.⁵¹⁻⁵⁴ Stern⁵¹ had previously shown that when monethyl hydrogen peroxide was added to a concentrated, highly active solution of liver catalase, the spectrum of the free enzyme disappeared and was replaced by two new absorption bands. Much later the new bands faded and the old spectrum reappeared. To measure the rate of the first reaction between enzyme and substrate, Stern and DuBois⁵² devised an apparatus in which monochromatic light of the same wavelength as the absorption bands to be studied penetrated a cell containing the reaction mixture and struck the cathode of a photoelectric cell. The photoelectric current was amplified and recorded through a string galvanometer. It was found that, while mixing was complete in 0.04 to 0.06 seconds, the time for half completion of the enzyme-substrate reaction varied from 0.06 to 0.26 seconds.

To check the accuracy of these methods, in which

both the photoelectric cell and the string galvanometer interposed definite time limitations, these investigators devised a direct method whereby the reaction cell was placed between the light source and the slit of the spectrograph, which was equipped with a falling-plate camera, so that continuous pictures could be obtained of the changes in the spectrum.⁵³ This method demonstrated first that mixing of the reagents was completed as quickly as 0.006 seconds, and that the enzyme-substrate reaction was completed before mixing was over.

While such promising studies are carried on, study of similar problems by the classic chemical procedures have continued to progress. Some of these have been admirably summarized in a volume of essays entitled *Perspectives in Biochemistry*,⁵⁵ published in honor of Sir Frederick Gowland Hopkins on his seventy-fifth birthday. Particularly interesting are the reviews by Needham of the chemical cycles in muscle contraction, and of Szent-Györgyi on his own work on the catalytic action of the four-carbon-atom dicarboxylic acids in cell respiration. His discovery of the function of these acids as a link between the foodstuff and the Warburg-Keilin oxidative enzymes is equivalent in interest to his demonstration that the stages in fermentation involving trioses were followed almost exactly by the four-carbon acids, which were in reality trioses stabilized by the addition of a terminal carboxyl group.

THE ENDOCRINE GLANDS

Glands Regulating Carbohydrate Metabolism

In 1936 this journal published an account of one of the most fruitful advances in endocrinology since the discovery of insulin.⁵⁶⁻⁵⁷ In his Dunham Lectureship Series, delivered at the Harvard Medical School in 1935, Houssay described a long series of experiments in his laboratory which showed unmistakably the intimate association between the secretion of the anterior lobe of the pituitary gland and the regulation of carbohydrate metabolism. His evidence consisted of three main points: (1) the great hypersensitivity of hypophysectomized animals to the injection of insulin, and their equally striking lack of sensitivity to the injection of adrenalin, (2) the improvement in the condition of depancreatized animals effected by removal of the hypophysis, and (3) the production of persistent diabetic-like states by the injection of anterior pituitary preparations.

These experiments, amply confirmed, made necessary a revision on a wide scale of previous notions concerning the mechanism involved in production of diabetes mellitus in man. It could no

longer be held that this disease was invariably of pancreatic origin, and that varying degrees of insulin deficiency resulted in varying degrees of impairment of the ability of the tissues to utilize glucose, terminating ultimately in total inability to oxidize it. It also became obvious that processes might exist under hormonal control that result in glucose production from noncarbohydrate sources, and that other hormones might act to increase or decrease carbohydrate utilization.

Recently the role of other endocrines in regulating carbohydrate metabolism has been extended through the work of Long and his colleagues.⁸⁰⁻⁸³ Removal of the adrenal cortex in cats, and maintenance of the animal over long periods by administration of potent preparations of cortin, permitted Long to ascertain (1) that adrenalectomy improves the total pancreatic diabetes to the same degree as does hypophysectomy, and causes a prompt disappearance of glycosuria in partially depancreatized rats, (2) that injections of extracts of the anterior pituitary fail to produce glycosuria in adrenalectomized rats, and (3) that the adrenalectomized rat shows a sensitivity to insulin due to cortical loss as well as the medullary deficit.⁸⁰ The only failure in the almost exact parallel between the removal of the adrenal cortex and the anterior pituitary is that cortical extracts which are potent so far as water and salt metabolism are concerned fail to restore glycosuria in a depancreatized, adrenalectomized animal to the degree that anterior pituitary extracts prove effective in hypophysectomized, depancreatized animals. However, enough evidence has been accumulated to indicate that the adrenal cortex plays an important part in sugar metabolism, both in normal and in diseased subjects.

The Sex Hormones and Growth-Promoting Agents

The appearance in 1937 of a second edition of Fieser's⁸¹ *The Chemistry of Natural Products Related to Phenanthrene*, a year after its first publication, indicates the enormous interest in these compounds. Elucidation of close relation between compounds which produce cancer and the internal secretions of the sex glands is of the greatest interest both to physiologists and to physicians. The retardation of the growth of certain tumors brought about by suppression of ovarian secretion has been known to clinicians for some time, and Allen⁸²⁻⁸⁵ is largely responsible for the demonstration that injection of follicular hormone in male or female mice will produce mammary cancer in susceptible strains. What is more interesting, cancer has at times been produced in regions other than in the mammary gland, where it is usually observed. The discovery of the chemical similarities between the cancer-producing substances and

the sex hormones places these studies upon a rational basis, and forms the starting point for future work on the physiology of normal and abnormal growth.

One of the most recent developments in this field is the study of the effect on cell growth of the well-known substance of this group, colchicine.⁸⁶ This drug, recognized for a great many years as a sovereign remedy for the gout, is now found by Lats to have a marked inhibitory effect on cell division in animals when injected in certain concentrations. What is more surprising, it seems to have its specific effect only at the metaphase stage of cell division. It becomes therefore a new and valuable method for studying rate of growth in a variety of conditions, since cells accumulate in metaphase from the time of injection to the time of sacrifice. Whether the growth-arresting property of colchicine has any relation to its effect in gout is at present a matter only for conjecture.

A noteworthy study in another field of endocrinology is that by Gilman and Goodman.⁸⁷ They have been able to detect the presence in the urine of the pituitary antidiuretic hormone, and to demonstrate that it is secreted in response to a demand for water conservation.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 24231

PRESENTATION OF CASE

First admission A thirteen-year-old, native-born, white boy entered the hospital with the complaint of lameness of two years' duration.

Seven years before entry he developed polydipsia, frequency and severe enuresis. He was admitted to another hospital two years later, where physical examination revealed slight enlargement of the heart and a blood pressure of 120 systolic, 85 diastolic. At that time his phenolsulfonphthalein test of renal excretion gave 10 per cent in the first hour and a total of 20 per cent in two hours. The nonprotein nitrogen of the blood was 75 mg per cent. An Addis determination of urine content showed a specific gravity of 1.012, a trace of albumin, 1,350,000 casts (upper limit of normal 10,000) and 500,000 red cells (upper limit of normal 600,000). After forcing fluids for ten days the nonprotein nitrogen was 26 mg per cent. About that time his physical development began to slow down, and during the two years before entry his height remained stationary. During the year after his entry to the other hospital there was no great change in his condition. His blood pressure remained below 108 systolic, 70 diastolic. The urine showed rare red-blood cells and granular casts, and on one occasion the nonprotein nitrogen of the blood was 56 mg per cent. Three years before entry to this hospital he had a mild attack of scarlet fever, and after a month of convalescence in bed began to have difficulty in walking and supporting his weight. There was associated dyspnea on exertion and easy fatigue. He also complained of pain in the lower lateral chest, bilaterally, which was aggravated by laughing or sneezing. His physical disabilities gradually progressed, until he was almost unable to climb stairs without support, and he began to use a walking stick. He was taken out of school from the fourth grade which he had had to repeat because of poor reading ability. At no time did his muscles appear to be larger than normal but rather appeared to decrease in size as his weakness progressed. He never had an exaggerated lordosis, but he developed a waddling gait and a bilateral valgus deformity of the knees. Two years before entry he had an attack of cramps in both hands and feet lasting

half an hour, with recurrence of the foot cramps at monthly intervals for three to four months. Occasionally his hips were sore, and shortly before entry he complained of painful stiffness in the joints of his little fingers. About nine months before entry his skin became coarse and dry, and his hair became thinner. He was seen in the outpatient department at that time, and a neurological examination revealed no significant findings except muscular atrophy and weakness with diminished to absent tendon reflexes. There was no characteristic distribution of weakness, and he was considered to present a problem of general deferred growth. His urine had a specific gravity of 1.004 and contained a slight trace of albumin, and the test for sugar gave a green reaction with sediment.

For many years he had had frequent sore throats until his tonsils and adenoids were removed five years before entry, which was two years after the onset of his illness. He had had whooping cough at the age of five, chickenpox at nine and measles at ten, shortly after his attack of scarlet fever. His physical and mental development had appeared to be normal up to the onset of his illness. He had had no visual symptoms, epistaxis, orthopnea, jaundice, melena, hematemesis, hematuria, dysuria, edema, puffiness of the face or any neurological symptoms, such as twitching or convulsions. His family history was negative except that his maternal grandmother had mild diabetes.

Physical examination revealed an undernourished, underdeveloped boy. The skin was dry and coarse, and there was generalized muscular atrophy and weakness. The tendon reflexes were increased in activity, but neither a Chvostek nor Trousseau sign was present. A forceful apex heart beat was felt in the fourth interspace, 6 cm from the midsternal line. The heart sounds were of good quality, and no murmurs were heard. The blood pressure was 120 systolic, 88 diastolic.

The temperature was 100°F, the pulse 128. The respirations were 28.

The urine was acid, had a specific gravity of 1.004 and contained the slightest possible trace of albumin, no sugar, 1+ acetone, many coarse granular casts and occasional red cells and white cells. The urine concentration test gave a maximum specific gravity of 1.006. The blood showed a red-cell count of 3,200,000 with 75 per cent hemoglobin, and a white-cell count of 9000 with 76 per cent polymorphonuclears. A phenolsulfonphthalein test of renal function gave 2 per cent excretion in two hours. The nonprotein nitrogen of the blood was 67 mg, the sugar 59 mg, the calcium 7.45 mg, the phosphorus 6.76 mg and cholesterol 187 mg per cent. The carbon-dioxide combining

power was 29.3 vol per cent, and the blood chlorides were equivalent to 100 cc of N/10 sodium chloride. The basal metabolism rate varied from $+7$ to $+18$ per cent. An electrocardiogram showed a tendency to left-axis deviation and low T waves.

X-rays of the bones showed generalized decalcification with widening of the growing epiphyseal lines and some irregularity of the metaphyses. In the upper ends of both fibulas, and in at least three metatarsal bones there were thin fracture lines with some increased density about them, so-called *Umbau-zone*. The sella turcica appeared normal and the skull was normal in size and shape. Dental films showed absence of the lamina dura in most of the teeth, and retardation of dental development. The chest x-ray was negative, and flat films of the abdomen, though somewhat unsatisfactory, showed no gross calculi or other abnormalities.

He was given a high-carbohydrate, high-vitamin and low protein diet, with calcium lactate and sodium gluconate. His fluid intake and output were very high, and he used a good deal of table salt with his meals. On the eighth day the nonprotein nitrogen of the blood was 62 mg., the calcium 817 mg and the phosphorus 404 mg per cent. The phosphatase was 1276 Bodansky units. The chlorides were equivalent to 94 cc of N/10 sodium chloride. The carbon-dioxide combining power was 56.9 vol. per cent. Eight days later a retrograde pyelogram showed a normal left ureter and kidney pelvis, and no evidence of calcification in either kidney. He was discharged on the eighteenth day essentially unimproved.

Final admission (eight months later) He was followed in the Out Patient Department. Two months after discharge his blood pressure was 118 systolic, 80 diastolic, and he was doing fairly well. Four months before entry the nonprotein nitrogen of his blood was 65 mg., the calcium 6.92 mg., the phosphorus 4.06 mg., the uric acid 5.7 mg and the sugar 130 mg per cent. The carbon-dioxide combining power was 25.8 vol per cent, and the chlorides were equivalent to 94 cc of N/10 sodium chloride. His appetite gradually became worse, and he lost a little weight. Four days before re-entry he began to vomit and continued to vomit all food and fluids taken.

Physical examination revealed an emaciated, lethargic boy showing marked evidence of dehydration. Otherwise the physical examination was essentially the same as before. The heart was apparently not enlarged, and the blood pressure was 118 systolic, 74 diastolic.

The temperature was 98.6°F, the pulse 96. The respirations were 24.

The urine had a specific gravity of 1.005 but was reported otherwise negative. The blood showed a red-cell count of 4,500,000 with 60 per cent hemoglobin, and a white-cell count of 29,000 with 91 per cent polymorphonuclears. The nonprotein nitrogen of the blood was 102 mg per cent and the carbon-dioxide combining power was 19.9 vol per cent.

He died on the day of entry.

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES The most striking finding is the decalcification shown in all bones examined, with a widening of the epiphyses which is characteristic of rickets. This is the bilateral line of diminished density with increased density around it, which was interpreted as fracture. It seems to me rather odd that it should be so symmetrical. I wonder if it is anything else. If it is not fracture, I do not know what it is. In the examination of the urinary tract the kidney outlines are rather faintly visible and seem to be quite small for a child of that size. I do not suppose one is justified from the x-ray examination alone in saying definitely what size the kidneys are, but one can sometimes make an intelligent guess as to whether they are large or small, and in this instance they appear to be small. There is no evidence of calcification in the kidneys. In the chest we see the same decalcification of the bony thorax that we see in other places, and a rather high diaphragm. In the lung fields the markings are quite prominent. The heart is perhaps a little enlarged to the left, but might not be abnormal. I should be inclined to think that Dr. Mallory would find that the heart weight was normal. There are no mediastinal masses—nothing in the chest to account for the dyspnea.

Then in the skull the anterior sutures are closed, which is unusual for a child of this age and may mean early closure, the posterior sutures are quite indistinct. In the teeth there is some retardation of growth and change in the periodontal membrane. I should not be certain that it is absent. It is a definite sign. I am sure it is found in parathyroid disease, but I am not certain that it is not sometimes found in other conditions. My feeling in this case is toward renal rickets rather than parathyroid disease.

DR. HAROLD L. HIGGINS What is his age from the epiphyses?

DR. HOLMES I cannot tell accurately enough.

to allow me to decide whether there is late development

DIFFERENTIAL DIAGNOSIS

DR ALFRED KRANES This is a very interesting and unusual story, and I think there can be very little doubt that we are dealing with a patient who had renal rickets. The clinical story should be discussed in two phases (1) the renal disease and (2) the skeletal disease—each one of which might better be considered independently.

The story is unusual because this patient came under observation two years after the onset of his first renal symptoms, and at that time the first accurate observations that were made showed that he did have a moderately severe degree of renal impairment with an elevated nonprotein nitrogen in the blood and a low specific gravity of the urine. Nevertheless, he managed to live for five additional years—a rather unusual survival period after renal insufficiency manifests itself.

It is always more or less of a guess as to what the renal lesion will be when presented with a case of nephritis. In this patient we are simply given a problem in renal insufficiency. We have absolutely no data on which to predict what type of lesion will be found. We have to rely mainly on probabilities. With the disease beginning at his age one has to think of congenital lesions of the urinary tract, the two most common of which are congenital hydronephrosis—for which there seems to be no evidence in the retrograde pyelogram—and polycystic kidneys—for which we also have no evidence, no abdominal masses having been palpated and the pyelogram showing no enlargement of the kidneys. Both these diagnoses seem rather unlikely. Another type of chronic renal disease in children which may lead to renal insufficiency is chronic pyelonephritis. However, there are no signs of infection, no pyuria has ever been found, and there are no chills or fever, except for one isolated temperature of 100°F. With as little evidence as is present here one can safely exclude chronic pyelonephritis.

We are left, then, with the diagnosis of chronic glomerulonephritis first, by exclusion and, secondly, because statistically it is the most common lesion at this age. This boy was not seen at the onset of his disease—at least no observations are recorded on him then—so that we do not know whether hematuria was present at the onset. It is frequently overlooked at the beginning of the acute nephritis, at least in the history. However, when he was observed two years later, at which time renal failure was present, hematuria was not found. In addition, his kidneys, as Dr Holmes

would lead me to believe that he did have a very small, contracted pair of kidneys, the result of chronic glomerulonephritis, and that the patient died in uremia.

There is one other possibility, in view of the bone disease, which we have to mention and consider seriously that is hyperparathyroidism, which will cause chronic renal disease and will also produce the changes that have been described in the skeleton. He had a very high blood phosphatase, although the remainder of the blood chemistry is atypical for hyperparathyroidism. We must remember, however, that the presence of severe renal impairment might mask the characteristic blood findings of hyperparathyroidism, particularly the phosphorus level. I think it is very unlikely that this patient had primary hyperparathyroidism. In the first place the statement is definitely made that there was no calcification in the kidneys, and the renal insufficiency of primary hyperparathyroidism is produced by a process called nephrocalcinosis, or deposits of calcium in the renal tubules which frequently show up by x-ray. Secondly, we have evidence that the renal disease started long before the bone disease, which is quite the reverse of hyperparathyroidism. One would have to have long-standing parathyroid hyperplasia to produce chronic renal insufficiency. Nevertheless, I do believe that this patient's parathyroid glands will very probably be enlarged, not because of but rather the result of prolonged renal insufficiency. We know that in chronic nephritis there frequently is enlargement of the parathyroid glands, and this patient with a renal insufficiency of at least five years' duration, and probably more, ought to have a good deal of enlargement.

We might speculate as to the cause of that enlargement. If one believes, and there is considerable reason for doing so, that one of the primary functions of the parathyroid hormone is to lower the renal threshold for phosphorus excretion, we can then explain the parathyroid hyperplasia as the result of phosphorus retention. The parathyroids become hyperplastic in an effort to reduce the phosphorus concentration of the blood. That such a mechanism was operating here seems likely, because, although this patient had a severe degree of renal damage, the phosphorus content of the blood was only slightly over 4 mg. That I think would be quite unusual in the absence of parathyroid hyperplasia. It ought to be 6, 7 or perhaps 8 mg per cent. Dr Albright and Dr Drake did some interesting experiments here several years ago on the production of parathyroid hyperplasia by the parenteral injection of phosphates into rabbits. They found that by keeping the blood phosphorus

constantly elevated they were able to produce parathyroid hyperplasia. Similarly in this case, if parathyroid enlargement is found, it will probably be secondary to the renal disease and phosphorus retention.

As regards his bone disease which has been described as renal rickets, — undoubtedly a poor term, — the bone changes that these patients have are not really those of rickets. Histologically they are osteitis fibrosa cystica — the same as in hyperparathyroidism, but the term "rickets" has been used for so long that it seems to be here to stay.

What the skeletal changes are due to, is again a matter of great controversy. There are three possible explanations for them, but which one is responsible, or whether all three are, has not yet been settled. The most obvious explanation — that the parathyroid enlargement and hyperplasia produce the skeletal abnormalities — has not found any experimental support. Several years ago a case similar to this in an adult was studied on the wards here, and it was found that the renal excretion of calcium, which in real hyperparathyroidism is much increased, was only slightly elevated. If the parathyroids were responsible for the skeletal changes, one would expect a marked increase of urinary calcium. However, in the case that was studied here, the urinary-calcium excretion was relatively normal. Even with damaged kidneys one would expect fairly good excretion of calcium.

The second explanation might lie in the chronic acidosis that these people have. We know this boy had an acidosis for at least eight or nine months, and the probabilities are that he had chronic acidosis all during the period of renal failure. Any long-standing acidosis will produce a picture in the bones which cannot be differentiated from osteitis fibrosa cystica. Bodansky and Jaffe were able to produce the typical picture of osteitis fibrosa cystica in dogs by prolonged administration of ammonium chloride. We have here the probable explanation of the skeletal changes.

A final explanation is the increased phosphorus excretion in the intestinal tract, which results in the precipitation of calcium phosphate. The ingested calcium is therefore not absorbed since it becomes insoluble, and as a result these individuals live on what amounts to a diet markedly deficient in calcium. Which one of these three above-mentioned possibilities is responsible has not definitely been settled, but the most probable is the chronic acidosis theory.

In summary, I should say that this patient had, primarily, a chronic glomerulonephritis, with a small, contracted pair of kidneys, and that he died in uremia. Secondary to the nephritis and phos-

phorus retention he developed parathyroid hyperplasia, and along with this, because of the prolonged acidosis, he developed the bone picture of osteitis fibrosa cystica. In addition, because of the prolonged course of his renal disease, I think it is quite probable that he had a rather marked degree of generalized arteriosclerosis.

DR. TRACY B. MALLORY: There is one point not particularly emphasized in the summary that would have been obvious if you had seen the child — his dwarfism. His growth was quite markedly retarded. He was short and much underweight as well. Does that in any way alter your feeling?

DR. KRANES: I think that prolonged renal insufficiency could produce the dwarfism by the same mechanism that the bone changes are produced.

DR. HAROLD L. HIGGINS: I think the cramps could quite well have been due to tetany, as his blood calcium was down to 7.5 mg per cent most of the time. The boy was 48 in. tall, which is the height of a boy about eight years old. As he was thirteen years and two months old, he was five years behind schedule so far as height was concerned. But his head measured 21 in., which is the average size for an eight-year-old child. He seemed to be a proportional dwarf and not simply a dwarf because of short extremities. The appearance of the skin, which was rather smooth, and the very scanty hair somewhat suggested a pituitary midget, but the general condition of the child was that which we frequently see in children who develop kidney insufficiency. They stop growing and develop what is known as renal rickets, which really is not rickets at all, although it probably is caused by the renal condition.

CLINICAL DIAGNOSES

Uremia
Chronic glomerulonephritis

DR. KRANES'S DIAGNOSES

Chronic glomerulonephritis
Renal osteitis fibrosa cystica
Parathyroid hyperplasia
Uremia

ANATOMICAL DIAGNOSES

Chronic nephritis
Healed pyelonephritis?
Cardiac hypertrophy, slight.
Pericarditis, chronic fibrous
Osteitis fibrosa, slight
Parathyroid hyperplasia, very slight.
Basophilism of the pituitary

PATHOLOGICAL DISCUSSION

DR. MALLORY The relation of renal insufficiency to osteitis fibrosa seems to be very well established, but what relation there is between renal insufficiency and dwarfism is still a very open question. I spent a good deal of time trying to find some information about it in the literature and must admit I had very little luck. We have seen here one case with marked so-called renal rickets, that is, marked fibrotic and cystic changes in the bone, without dwarfism. This case today is somewhat over on the other side. It showed a marked grade of dwarfism and changes in the bone that one can recognize as similar to osteitis fibrosa, but they were very early. Quite to our surprise, the parathyroids were not large. We had fully expected that we would find very big ones, as Dr. Kranes predicted. We were only able to identify three. When all the parathyroids cannot be found it is quite certain that they must be small. Those we did find were barely larger than normal and only with the microscope could one be sure there was some hyperplasia. Similarly, the changes in the bones, though present, looked as if they were of comparatively short duration. So this case on the whole supports the theory of the bone changes' being secondary to acidosis. At least we know that acidosis was present for a considerable period of time. The thyroid and adrenals were perfectly normal. The kidneys were shrunken, and distinctly smaller than normal. At autopsy we thought the ureters were slightly dilated. Their diameter was estimated at 5 mm. which would be large for a child of that age. The largest proportion of cases of renal rickets reported have been in association with congenital dilatation of the ureters. I believe we must add this case to the list, though the anomaly was present only in a very slight degree. It would be rash to try to state dogmatically the exact nature of the renal lesion. It was an end stage of a very chronic process with no evidence of progressive damage at the time of autopsy. There were quite a significant number of perfectly normal glomeruli which would be a little surprising if it were the end stage of glomerulonephritis. Certainly no active glomerulitis was present. The tubules, in contrast, were reduced in numbers out of proportion to the destruction of glomeruli, and the degree of interstitial fibrosis was quite marked. The pelvises were not dilated, and sections which included the pelvis showed no signs of inflammation. Certainly there was no pyelonephritis at the time of death. I can conceive of a kidney such as this being the end result of a completely healed pyelonephritis or of interstitial nephritis of the type occasionally seen with

scarlet fever, but cannot rule out with certainty a completely burned-out glomerulonephritis.

DR. KRANES What about the arteries?

DR. MALLORY They did not show any great amount of atheromatosis. The heart weighed 175 gm., which would probably be within the normal limits for a boy of thirteen if he were of normal size, but seemed hypertrophic in proportion to the general development.

I found the pituitary very interesting. It was of normal size, but the sections show unusual proportions of the three types of cells. Chromophobes, which normally make up two thirds of the total, were greatly reduced—to about 20 per cent I should guess. Acidophils were relatively and perhaps absolutely increased in number and basophils were unquestionably greatly increased in number, both absolutely and relatively. I should estimate them at nearly 25 per cent of the total. Of course not too much emphasis should be placed on estimates unsupported by an actual count, but the decrease in chromophobes and the increase in basophils are so marked in this case that there can be no doubt that the ratios are very abnormal. In comparison with an adult pituitary these changes are certainly significant. I must confess to knowing little about the child's pituitary, but in view of Parsons's* findings I think we may assume the changes are abnormal for the child as well.

CASE 24232

PRESENTATION OF CASE

A fifty-two-year-old American businessman was admitted complaining of cramping abdominal pain.

For one week before entry the patient suffered from intermittent cramplike pain in the lower abdomen. The pain was sufficiently severe to cause him to double up and on several occasions morphine was required for relief. Between pains there was a persistent, dull, aching soreness in the lower abdomen more pronounced on the left side. During the week of illness the temperature ranged between 100 and 102°F. Associated with the cramps there were nausea and vomiting, and the patient was unable to eat very much food. On occasion the pain was accompanied by a "bearing down" sensation and a great urgency to defecate. Throughout the week of illness there were almost constant bubbling and grinding noises in the abdomen.

The patient's stools had always been rather loose.

Parsons, R. J. The pituitary gland and its relation to age, hypertension and pathological processes: a study of 107 unselected pituitaries. *Medical Papers Dedicated to Dr. Henry A. Christian*. Baltimore: Waverly Press, Inc. 1936. Pp. 366-405.

in consistence and for about fifteen years he had had three to six watery bowel movements daily. Since the onset of the current attack the frequency increased, but the amount of each movement became scanty. The stools never contained pus or blood. There was no loss of weight.

About three years before coming to the hospital the patient had had an attack of pain similar to the present illness. At that time there were nausea, vomiting, fever and frequent, small stools. On occasion since then there had been brief twinges of lower abdominal pain lasting for a day or two.

Physical examination showed a well-developed and nourished man in no acute distress. The pupils were equal and reacted normally to light. The lungs were clear. The heart was normal. The blood pressure was 125 systolic, 80 diastolic. The abdomen was full and soft. No spasm was elicited. A smooth, slightly tender, baseball-sized mass was palpated in the left iliac fossa. It appeared to be fixed in this region. Peristalsis was definitely hyperactive, and the upper abdomen slightly tympanic.

The temperature was 99°F, the pulse 90. The respirations were 22.

Examination of the urine was negative. The blood showed a red-cell count of 4,140,000 with 75 per cent hemoglobin, and a white-cell count of 14,000 with 78 per cent polymorphonuclears. The nonprotein nitrogen of the blood was 21 mg per cent, and the serum chlorides were equivalent to 100 cc N/10 sodium chloride. A blood Hinton test was negative.

A plain x-ray film of the abdomen showed a moderate quantity of gas in the small bowel and colon. The loops of small bowel were not appreciably dilated. There were no areas of calcification in the region of the kidneys, but small areas were seen in the true pelvis near the lower ends of the ureters.

A barium enema passed to the cecum without delay and entered the terminal ileum. An area of the colon at the junction of the descending portion and sigmoid showed a constant narrowing for a distance of about 5 cm. The mucosa throughout this area was intact, and no intraluminal defects were present. This area evidently corresponded to the palpable abdominal mass. On the films taken after evacuation barium was seen extending out into the soft tissues beyond the lumen of the bowel at the point of narrowing. Multiple small diverticula were seen throughout the sigmoid and lower descending colon. There was gas in the small bowel in close proximity to the lesion in the colon.

On the second hospital day a laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR EDWARD L. YOUNG: Cramp-like abdominal pain in the abdomen associated with nausea is always indicative of some irritation of the bowel, and this may be anything from food injudiciously chosen to the partial obstruction of a malignant tumor. In this particular case it had persisted for a week, and that alone would seem to rule out a digestive upset. The abdominal borborygmi that are spoken of merely back up the diagnosis of irritation and suggest a partial obstruction. The "bearing down" sensation and the desire to defecate suggest that the trouble was fairly low down in the large intestine. The fact that he had had three to six watery movements a day for fifteen years suggests a habit peculiar to the individual rather than a background of disease. The lack of pus and blood also tends to rule out any ulcerative condition. The history suggests that there had been something present for at least three years. That, plus the facts that there had been no loss of weight or apparent change in his general condition and no evidence of abnormality in the stool, other than the looseness, would make cancer very unlikely.

On examination there was a slightly tender mass in the left iliac fossa, a slight fever and a somewhat elevated white count. The examination and laboratory work were otherwise essentially negative. The x-ray tells us that there was no evidence of growth in the large bowel even at the area corresponding to the palpable mass. It does add two facts of great importance, which, taken with the other evidence, would seem to make the diagnosis certain. First, there were diverticula in the sigmoid and descending colon and, secondly, the barium seemed to extend outside the lumen of the bowel into the soft tissue at the point where the mass was palpable. Although it is possible for a single diverticulum of the large bowel to exist and perforate, it is much more usual for them to be multiple, thus increasing the numerical chances of infection and perforation. In this individual it seems to me we are entitled to say with a very high degree of certainty that he has diverticulitis with perforation and abscess formation. I think the surgeon should plan his attack on that basis.

Is there anything else that should be considered seriously? We have ruled out cancer. Appendicitis and the other possibilities such as solitary ulcer, amebic granuloma, and so forth would seem to me too rare to be seriously considered.

CLINICAL DISCUSSION

DR RICHARD H WALLACE Dr Arthur W Allen operated on this case and found the mass to consist of a loop of sigmoid with an abscess on its mesial side walled off by small intestine. The abscess cavity contained about 120 cc. of thick foul pus, and when this was removed by suction, there was a necrotic defect in the sigmoid the size of a quarter. Closure of the defect seemed impossible and drainage on the mesial side, where small bowel could not be excluded, seemed unwise. The only reasonable alternative, even in the presence of so much infection, was resection, this was done by freeing the sigmoid and removing the involved area. The two ends of the cut sigmoid were brought out close together in the wound. Stab-wound drainage was established in the lateral gutter where the retroperitoneal space was opened to free the sigmoid. The patient had a surprisingly smooth convalescence and has since had the ends of his sigmoid united so that he is at present quite well.

CLINICAL DIAGNOSIS

Diverticulitis of sigmoid

DR YOUNG'S DIAGNOSIS

Diverticulitis of sigmoid, with abscess formation

ANATOMICAL DIAGNOSIS

Diverticulitis of sigmoid

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN The resected specimen of sigmoid contained several small diverticula, the largest measuring about 1.5 cm in depth and 0.5 cm in diameter. The mucosa around one of these diverticula was markedly congested and further exploration showed that this one opened into the ragged abscess cavity in the pericolic fat that was broken into at operation. The surrounding fat was quite indurated. Histologically there was no evidence of cancer.

DIFFERENCES IN OPPORTUNITIES FOR HEALTH

PERHAPS one of the greatest problems before humanity is the lack of application of accurate knowledge to the prevention and cure of illness.

Although we are confronted with certain unsolved questions relating to etiology and treatment of disease, science has brought to full understanding the essential facts of so large a proportion of the disorders of human beings that the sum total of medical and allied resources outweighs the deficiencies. But even so the preventable diseases are not being prevented and the curable ones are not being cured, to a deplorable degree.

If there is doubt about the truth of this last statement, the article under the above caption by Mountain and O'Hara in *Public Health Reports*

(53 485-496, 1938) may be read with interest. These authors record statistical evidence showing the relative incidence of illness existing in families comprising certain groups, living under different financial resources. For example, the rate in families on relief exceeded that among the gainfully employed by a large figure, thereby indicating that poverty is an important determining factor.

The study of this subject necessarily includes the relation of preventive medicine to the problems involved. In this latter field, agencies other than those connected with services rendered by physicians share with the practitioner the responsibility of dealing with existing conditions.

How far poverty is an indication of low intelligence or misfortune is an important question in dealing with human distress. Here the attitude of the state has its place, for the ratio of illness in families with incomes of \$3,000 or more of 156 per 1000 persons, as compared with 188 in the less than \$1,000 group and 262 for those on relief, calls for explanatory studies. Mortality as well as morbidity rates in these several income groups seem to carry the same implication as that shown by statistics relating to deaths due to tuberculosis, pneumonia, cancer, heart and kidney diseases, infantile diseases and accidents.

So far as inadequate medical care is a contributory factor in ill-health, there was evidence tending to show that the lower the income the less medical service is rendered, except in the group of hospitalized indigents. The statistics relating to surgery are also of interest in this respect, for people with little money are apt to neglect surgical attention except in emergencies.

In dealing with all health matters there seems to be a tendency, among certain people, to regard the medical profession as blameworthy for unsatisfactory conditions, and too often there have grown out of this misconception arguments for state medicine which, in the opinion of some politicians, seem to require the employment of physicians for the treatment of all illness at government expense.

A consideration of all factors involved in this subject shows that medicine alone is not the cure-all for existing conditions, but that together with

medicine there must be the co-ordinate confluence of public-health, social and economic measures. Even with all these agencies geared to high efficiency, progress will depend in large measure upon the higher average intelligence of the people. Ignorance, prejudice and shiftlessness are now, and will be for some time to come, obstacles in the way of better health.

Medicine will do its part individually and collectively. It only asks for fair and courteous treatment by the people.

A CENTURY OF MEDICINE

THE most important period of time through which the world has ever passed, or is likely to pass, is one's own lifetime. From the heights of our sophistication of animation we look back with real pity upon the dweller in the Dark Ages, groping in the shadows of the intellectually unenlightened period in which he lived. To him, however, there were no Dark Ages except, perhaps, in history. As with us and as with our grandfathers of the incriminating horse and buggy addiction, so with him, he lived in the glorious present, the future yet unborn, the past usually forgotten.

Our past one hundred years, however, have been different, according to Dr. Major G. Seelig, director of research of the Barnard Free Skin and Cancer Hospital, St. Louis, in an address before the St. Louis Medical Society on the occasion of its centennial celebration last April, which was recently published in *Science*. The seventeenth century, Dr. Seelig tells us, was a time of individualism run riot with great writers, great painters, great musicians and great philosophers, and in medicine, Harvey and van Leeuwenhoek.

The eighteenth century was one of "tedious and platitudinous formalizing" with only such high lights as Morgagni, the Hunters, Jenner, Auenbrugger and Benjamin Rush, but following it came the later renaissance of the nineteenth century. During this century what we know as modern man emerged, and in this century modern medicine began, established on the theories of evolution, the atomic theory of Dalton, the law of the conserva-

tion of energy, the establishment of organic chemistry and the annihilation by Pasteur of the doctrine of spontaneous generation.

With this roadbed prepared on which modern vehicles could move, we were ready for surgical anesthesia, and the nearly simultaneous discoveries of nitrous oxide, ether and chloroform. We were ready for antiseptics and asepsis, and modern surgery, we were waiting for cellular pathology, bacteriology, epidemiology and sanitation, experimental physiology was bound to come, and Roentgen and the Curies needed only their opportunity.

One lesson to be borne well in mind, however, is that no tub rests entirely on its own bottom. The accomplishments of any period are dependent on those of the period that preceded it. Dr. Seelig well recognizes this in closing his address with Tennyson's quatrain:

Read my little fable,
He that runs may read
Most can raise the flowers now,
For all have got the seed

CASE HISTORY NO. 75 PARTIAL PLACENTA PREVIA

A forty-eight-year-old Irish-American nonipara was admitted to the hospital at term for the treatment of vaginal hemorrhage. She had had crampy abdominal pains and backache for three weeks preceding entry. She had passed considerable bright-red blood by vagina one week before entry. There was some staining and the passage of clots daily during the next week until the night before entry, when she had another alarming hemorrhage. The bleeding was not associated with pain.

The family history was negative. The patient had always been well. She had had seven normal full-term deliveries and one miscarriage at the third month. Her menstrual periods began the age

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

of thirteen and had always been regular and normal except for interruptions due to pregnancy

Physical examination revealed a well-nourished, normally developed woman. The skin was dry and slightly pale. The general physical examination was negative except for varicosities of both lower legs and the vulva, and edema of both ankles. The temperature was 98.6°F., pulse 84, respirations 20 and blood pressure 128 systolic, 90 diastolic. There was some old and fresh blood about the vulva. Abdominal palpation revealed a term pregnancy, position LOA, uterus of normal consistence, and fetal heart absent. The pelvic measurements were: intercrural, 32 cm., interspinous, 31 cm., external conjugate, 20 cm., and transverse diameter of the outlet, 9 cm. A catheter specimen of urine was straw-colored and acid, and contained a large trace of albumin. The sediment was negative, as was an examination for sugar.

The patient was immediately grouped for transfusion and prepared for examination. Under gas-oxygen and ether anesthesia, the cervix was found to be two-fingers dilated. There was a partial placenta previa, which accounted for the vaginal hemorrhage. A Braxton-Hicks' version was easily performed. One foot was pulled down into the vagina. A dead and macerated baby was delivered in twenty minutes by means of strong traction on the leg. There was moderate difficulty with the aftercoming head. The baby weighed 9 lb. The cervix was inspected because of profuse bleeding. A right lateral tear was repaired with interrupted chromic catgut sutures.

The patient was transfused with 500 cc of citrated blood. The blood pressure was 64 systolic, 42 diastolic, fifty minutes after delivery, the pulse was 96, and the respirations 20. In spite of the transfusion the patient began to complain of air-hunger and went into severe shock within a half hour. A second transfusion was administered. Her condition, however, did not improve, so a supracervical hysterectomy was performed under light gas-oxygen and ether anesthesia. A rupture of the uterus into the right broad ligament was encountered at laparotomy. This rent was repaired following amputation of the uterus. One drain was inserted through the cervix and another was brought out through the abdominal wound. Since her condition was very poor at conclusion of the operation, she was given a third transfusion. The blood pressure then rose from 50 systolic to 80. During the next four days she received fluids by intravenous and subcutaneous injections, as well as two more transfusions. She developed, however, rapidly increasing abdominal distention which was not relieved by Pituitrin, enemas and flaxseed poultices. She expired on the fourth day, with signs of general peritonitis.

Comment This is a very interesting case. The large trace of albumin and the dead baby suggest a toxemia with a separation of the placenta, but the examination revealed a partial placenta previa. It may well have been that the toxemia was the cause of the dead baby and the separation of the placenta. It is not at all common for placenta previas to bleed enough to cause intrauterine death unless the mother is exsanguinated.

The treatment of this case was poor. A bag probably would have been quite successful. As the partial previa was a very minor affair, rupture of the membranes alone might have been sufficient. The Braxton-Hicks' maneuver should have been carried through conservatively, a leg merely being brought through the cervix to act as a tamponade and the rest of the delivery left to nature. Rapid delivery caused this ruptured uterus, and the death is definitely attributable to the management of the case rather than to the partial previa, which was the cause of the bleeding.

DEATHS

HEALY — HARRISON T. HEALY, M.D., of New Bedford, died June 1. He was in his fifty-sixth year.

Born in New Bedford, he was graduated from high school, received his doctor of pharmacy degree from the Massachusetts College of Pharmacy and was awarded the degree of doctor of medicine from the Baltimore Medical College in 1907. Dr. Healy began practice in New Bedford and served as physician to the welfare department and as parochial school medical inspector.

A former fellow of the Massachusetts Medical Society, he was a member of the New Bedford Medical Society and the Massachusetts Clinical and Surgical Association.

His widow, four sons, two daughters, a brother and a sister survive him.

ILSLEY — FREDERICK R. ILSLEY, M.D., of Medford, died April 28. He was in his sixty-ninth year.

Dr. Ilsley received his degree from the Harvard Medical School in 1892. He was a fellow of the American Medical Association and a retired fellow of the Massachusetts Medical Society.

MISCELLANY

DANGEROUS TICK BITES AVOIDABLE BY A FEW SIMPLE PRECAUTIONS

Fear of the tick that carries Rocky Mountain spotted fever in the East need not keep people indoors this summer. The tick's principal danger lies in its bite. Bites can be avoided by a few simple precautions, according to Dr. F. C. Bishopp, of the Bureau of Entomology and Plant Quarantine, United States Department of Agriculture. At the same time, Dr. Bishopp emphasizes, failure to take these precautions may have serious consequences. The East has an unusually large number of common dog or wood ticks this year—some being reported for the first time from vacant city lots. Even though only one in several hundred of these ticks may carry the fever virus, that one tick, which cannot be distinguished from the rest

medicine there must be the co-ordinate confluence of public-health, social and economic measures. REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on March 8, Dr A. Baird Hastings presiding

The medical case was presented by Dr Carl Shepard. The patient, a nineteen-year-old white male, had noted occasional swelling of his face and feet at irregular intervals for seven months. He had experienced blurring of vision for four months, and there had been nocturia for three months. He had boiled his urine, and found that it solidified in the container. Examination on entry to the hospital revealed generalized edema, ascites, bilateral hydrothorax, pulmonary congestion and retinal edema with white retinal exudate. The blood pressure was 190 systolic, 145 diastolic. The urine contained a large trace of albumin, and a few red and white blood cells. The urinary excretion of albumin amounted to 40 gm per day. The blood nonprotein nitrogen and blood urea nitrogen were not elevated. The total protein of the blood serum was 3.5 mm per cent, with reversal of the albumin globulin ratio. The red blood-cell count was 2,700,000, and the hemoglobin 48 per cent (Sahli). The phenolsulfonphthalein excretion was reduced to 25 per cent in two hours. The patient was given a high protein, salt free diet, and fluids were restricted to 1000 cc. per day. There was a marked diuresis and loss of 30 lb in weight. Dr Henry Christian remarked that this was a typical case of glomerular nephritis.

The surgical case was a forty three year-old white male, who had suffered a bout of phlebitis of his left leg twenty-five years previously and had subsequently developed swelling of the leg which had reached very large dimensions and had been subjected to two plastic operations nine years later. Seven years before entry he suffered an attack of multiple abscesses in the leg, and six months previously, after trauma to the lower leg, he again experienced sepsis in the water-logged tissues. On entry to the hospital the patient was febrile and showed a red, swollen, edematous leg, which measured 90 cm. in diameter at the mid-calf. After treatment with moist heat and elevation, the edema subsided and 30 lb of weight were lost due to drainage of fluid from the leg. Two plastic

is an agent of death. No cure for Rocky Mountain spotted fever is known. Its mortality rate is one out of every five persons infected.

After passing the first part of its life as a small parasite on field mice, the tick waits in tall grass and underbrush for larger host animals. Cutting all grass and underbrush around houses and pathways, therefore, is one way to protect dogs and people from tick bites.

Keeping ticks from gorging themselves on the blood of dogs is another protective measure. A pair of forceps is all that is needed in removing ticks from dogs to which only a few have attached themselves. Dusting every five days with derris powder is necessary for dogs supporting a large number of ticks. Ticks should be handled with great care, Dr. Bishopp points out. Infection can be contracted by crushing a tick full of blood from an animal that has had the fever.

Boots laced up over trouser legs protect men walking through tick infested areas, as ticks are usually picked up from grass or weeds close to the ground. Ticks always work their way upward before attaching themselves to their human host. The back of the neck and head are their favorite feeding places. Careful examination of heads, especially children's, at least twice a day, will reveal the presence of a tick in time to prevent a fatal bite. Examination of the whole body is necessary after exposure to ticks. An effective way to de-tick clothes is to place them in a vessel that can be tightly covered, and set on top of them a pan containing half a teacupful of carbon tetrachloride or carbon disulfide. A few hours of such fumigation kills the ticks.

"Don't wait for the doctor to remove a tick," Dr. Bishopp warns. The important thing is to get the tick off as soon as possible. Anyone can disinfect the bite and the surrounding tissues by inserting into the exact spot where the tick was attached a round toothpick that has been dipped in iodine and drilling it in slightly.

The American dog tick is widely distributed throughout the United States east of the Rocky Mountains, as well as in western and northern California and in parts of Oregon. It is most numerous along the eastern coast from Massachusetts to Florida, especially within a few miles of the shore. Both Texas and Florida have a great many ticks—also some inland areas, such as southern Iowa and parts of Wisconsin and Minnesota. Islands off the coast of Massachusetts are heavily infested with ticks, especially Martha's Vineyard, Nantucket and Naushon. Tick numbers fall off along the sea coast from Marion, Massachusetts, westward. The Narragansett Bay islands are rather heavily infested. A few ticks have been reported on the west side of that bay and as far west as Stonington, Connecticut. There are large numbers of ticks on Long Island, especially the eastern half, and along Chesapeake Bay in Maryland. They are rarely seen west of the Blue Ridge. — *United States Department of Agriculture*

WHAT MIDWESTERN SMALL-CITY FAMILIES SPEND FOR MEDICAL CARE

Midwestern small-city families are more likely to economize by not seeing the dentist, the oculist or even the doctor than by not buying supplies for the family medicine chest, when funds run low. This tendency is indicated in a table of medical expenditures for 3118 native white non-relief families living in seven representative cities in five midwestern states. The table is a part of a nationwide study of how much money the American family makes and how it is spent, conducted under the direction of Dr. Louise Stanley, chief of the Bureau of Home Economics, United States Department of Agriculture.

The cities studied were Lincoln, Illinois, Boone, Iowa, Columbia and Moberly, Missouri, Mount Vernon and New Philadelphia, Ohio, and Beaver Dam, Wisconsin.

Low-income families consult dentists less frequently than doctors, and visits to the oculist usually are omitted entirely. But a majority of families at all income levels (67 to 92 per cent) reported expenditures for medicines and drugs during the twelve-month period studied in 1935-36. Amounts spent for medicine, however, were not high, averaging \$6 to \$21 per family per year at the different income levels. Averages were based on all families including those that made no purchases for the medicine chest.

Income for the year reached the \$500 level before as many as half the families reported expenditures for a physician. Incomes of nearly three times this amount (\$1250-\$1499) were reached before as many as half the families had any expense for the dentist during the year. Even at the \$4000-\$4999 level only one family in four paid an oculist fee.

Fewer than 40 per cent of the families in the lowest income class studied (\$250-\$499) spent money for doctors fees during the year, fewer than 12 per cent spent for dentists' services, and none of these families incurred any expense for an oculist. However, 67 per cent bought some medicine.

Approximately half the families in the second lowest income class studied (\$500-\$750) had expense for the physician, one in four, for the dentist, and practically none—less than 0.5 per cent—for the oculist. Three families out of every four bought some medicine-chest supplies.

Nearly all families of income levels above \$500 (90 to 99 per cent) had some expenditure for medical care during the year. But even at the highest income level studied (\$5000 to \$10,000) only three families in four reported expense for a physician, four families in five for a dentist, and fewer than one in four for an oculist.

It is evident that a majority of families with very low incomes did not have periodic physical examinations by a doctor and did not have the condition of their teeth checked regularly by a dentist," says Dr. Stanley. "Average amounts spent for medical care in low income groups were not sufficient to pay for such routine services for all family members, even if the costs of serious illnesses had not been added in many instances. Since it is likely that families with low incomes need even more medical care than those that are well-to-do, these figures seem to indicate inadequate health measures. They support the contention of many social workers and others, that society should help provide adequate medical care for those who cannot pay the cost." — *United States Department of Agriculture*

NOTES

The University of Montreal has conferred the doctorate of science on Dr. M. L. Fernald, Fisher professor of natural history at Harvard University. The presentation was made preceding a course in botany given at the university by Dr. Fernald. — *Science*, June 3, 1938

Thirty-three appointments to the teaching and research staff of the Harvard Medical School were recently announced as follows:

Franz J. Ingelfinger, M.D., Harvard '36, as assistant in medicine, John C. Larkin, M.D., Johns Hopkins '35, as assistant in roentgenology, Joseph Meyer, M.D., Northwestern '36, as assistant in medicine, Lewis Dexter, M.D., Harvard '36, as research fellow in medicine, Arnold Iglaier, M.D., Cincinnati '37, as research fellow in medicine, Robert

membrane is impermeable to base, to phosphate and to sulfate. But during metabolic activity, base and phosphate pass in one direction or another, apparently in accordance with the needs of the cell. Movements of these substances are not accomplished merely by diffusion; they must involve chemical reactions.

Various experiments have indicated that the principles which control the exchanges of water and solutes between the red blood cells and serum also control the exchanges between the cells of all tissues and the interstitial fluid. Analyses have indicated that approximately 20 per cent of muscle tissue has the composition of an ultrafiltrate of serum, that is, so far as inorganic elements are concerned it contains chiefly sodium and chloride. Diffusion experiments indicate that there is a barrier in muscle tissue which differentiates about one fifth of the tissue from the other four fifths. Sodium, chloride and inorganic phosphate diffuse readily into one fifth of the muscle mass but do not cross the barrier into the cell (under resting stable conditions), while urea diffuses readily throughout the whole mass. Under the stimulus of glucose and insulin the concentration of phosphate esters in the muscle increased, indicating that, as in the red blood cell, the stimulus of metabolic activities initiated chemical processes which conveyed phosphate across the cell membrane that it ordinarily did not traverse.

The percentage of interstitial fluids was measured more directly by means of injecting substances which were not normal constituents of serum and which would pass freely through vascular walls without penetrating cells. Three substances were utilized for this purpose: a sulfocyanate, a sulfate and sucrose. Determinations of the distribution of these substances throughout the body again indicated that there is a barrier which separates the fluids of the body, in a broad way, into two compartments, of which one, into which these substances chiefly or solely diffuse, makes up roughly 20 to 30 per cent of the body weight.

By using the same principle but employing thio-urea which possesses most of the chemical and physiological properties of urea but is excreted completely unchanged in the urine, an attempt was made to measure the total water in the body. The volume of distribution of this substance varied from 68 to 70 per cent of the body weight—values consistent with accepted conceptions of the water content of the body.

Studies of the distribution of sodium sulfate throughout the body after injection of hypertonic solutions of this substance again gave results compatible with the theory that sulfate, sodium, chloride, and sulfocyanate were distributed over an identical fraction of the total water of the body, and that this fraction, approximately one fifth of the body mass, increased in volume by one liter. This expansion in volume must have been accounted for by acquisition of fluid from other parts of the body, namely the cells, since the hypertonic solution increased the osmotic pressure of the interstitial fluid, and water was withdrawn from the cells to restore osmotic equilibrium.

Tissue cells then, appear to resemble red blood cells in their general behavior: they seem to contain less sodium and to be more nearly if not completely devoid of chloride. When the concentration of sodium in the interstitial fluid changes, osmotic equilibrium is restored by transfers of water to or from the cells without transfers of base. There is no evidence that base is admitted to or discharged from the cells in behalf of osmotic equilibrium *per se*. The concentration of sodium in the interstitial fluids controls the water content or size of the cells. Consequently, it must determine the dilution of the

cellular constituents. The actual quantities of these constituents in the cells, however, appear to be controlled by entirely different mechanisms. There must be some means by which potassium, phosphate and other chemical substances are restrained in the cell to protect the integrity of the cellular composition. It is equally essential that there be some means of dissolving this restraint when need arises in the cells for more of these materials or for the discharge of any excess. Apparently the regulation of these restraining forces is delegated to the metabolic processes of the cells, thus insuring automaticity.

The tissue cells differ from the resting red blood cells with respect to the passage of potassium across the cell membrane. Apparently potassium diffuses freely throughout all the water of the body, and in addition, variable amounts enter some or all the tissue cells. Whether or not this fraction is taken *into* the cells by means of diffusion, it must be restrained *within* the cells by some other mechanism. Phosphate diffuses freely through the interstitial fluids but not into the cells. A certain amount does penetrate the cells. It must be supposed that this fraction gains access to the cells and is there retained by something other than diffusion.

These phenomena may be correlated as follows: the cells and interstitial fluid are in osmotic equilibrium, this osmotic equilibrium is maintained in spite of the extreme diversity of the two mediums by virtue of the fact that the interposed membranes do not allow free interchange by diffusion of a variety of substances, especially protein, sodium, chloride and phosphate. Sodium and chloride, in fact, seem to be almost completely, if not completely, excluded from the cells, although they are the chief inorganic components of interstitial fluid. It follows that any changes in the concentration of sodium in the interstitial fluid must result in an exchange of water that will restore equality of osmotic pressure between the two mediums. The volume of the intracellular fluid must therefore depend upon the concentration of sodium in serum. Ordinarily, the concentration of potassium in interstitial fluid is only a small fraction of the concentration found in cells. Nevertheless, when potassium salts are added to the system, potassium enters the cells in such proportions as to give the impression that extracellular and intracellular potassium are in simple diffusion equilibrium. If the cell membrane is freely permeable to potassium, this permeability must be restricted to a small fraction of the intracellular potassium, since the concentration of potassium in interstitial fluid is so low. The major portion of the intrinsic potassium of cells, since it does not diffuse outward, must be restrained from free diffusion by some force other than mere impermeability of the envelope of the cell.

Dr. Peters cited several observations illustrating the inferences to be drawn from the above stated hypotheses. Gamble found that in the dehydration of starvation acidosis potassium as well as sodium was wasted, a wastage which also occurred in the diuresis produced by acidifying salts. This wastage of potassium was not due to losses in extracellular sodium with resultant changes in intracellular potassium, since even with extreme depletion of body sodium there were only insignificant losses of potassium. In Addison's disease and in some animals after adrenalectomy, sodium wastage is accompanied by retention of potassium, although there is no rise of serum potassium. The potassium apparently enters or becomes imprisoned in the cells. Analyses of the tissues of rats after adrenalectomy have shown that there is an increase in cellular potassium without a comparable increase in water. This exemplifies the accumulation in the cells of osmotically in

operations were performed by Dr John Homans, with removal of large masses of fibrous, edematous tissue. Following each operation there were severe septic complications which were treated with Prontylin with good results. A third plastic operation was not followed by infection. Following granulation, very large Thiersch grafts were applied.

Dr Homans commented on the case, and stated that it was unusual to observe a case of elephantiasis nostra complicata by a suppurative sort of infection. In experimental elephantiasis it has been noted that, with the rise in the protein percentage of the tissue fluids, the animals are prone to attacks of fever due to non suppurative streptococci. This patient experienced suppurative attacks. The treatment consisted of removing all the tissue down to the muscle, bone, tendons, and so forth, beneath the aponeurosis.

Dr John P Peters, professor of internal medicine at Yale University School of Medicine, delivered the paper of the evening, speaking on the subject "Exchanges between Cells and Interstitial Fluids." Dr Peters presented a résumé of experiments performed in attempts to elucidate the processes by which water and various solutes, particularly inorganic constituents, find their way back and forth between cells and the interstitial fluids by which they are surrounded. These experiments were of two kinds: first, experiments in which the red blood cell was used as a model of general cellular reactions, secondly, investigations on the distributions of various solutes in the body.

Although the red blood cell is highly differentiated and unique in many respects it was particularly suited for these experiments because it could be isolated for analysis from its interstitial fluid, and because its metabolic processes could be brought to a standstill by chilling.

There is good reason to believe that the contents of the red blood cell have the same osmotic pressure as the blood serum and are in osmotic equilibrium with the latter. This means that in spite of differences in composition of the two mediums, cells and serum contain, per unit of water, the same concentrations of osmotically active chemical components. The differentiation of the two mediums depends on the highly selective permeability of the cellular membrane, which appears to be quite freely permeable to water, urea and certain other simple organic compounds, and to glucose under certain conditions. If water is added to blood it distributes itself between cells and serum in the same proportions as the water which was originally present in these mediums. The cells will therefore swell. Since urea can cross the membrane freely it will have no effect on the volumes of the cells, and solutions of urea will act exactly like equal amounts of water. If the cells were not quite impermeable to protein, hemoglobin would escape into the serum. Since the molecular concentration of protein in the red cells is more than three times as great as that in the plasma, it might be expected that the osmotic pressure of the cellular contents would be far greater than that of the serum. It is, of course, a similar difference in concentration of protein between plasma and interstitial fluids that, according to the Starling theory, balances the hydrostatic forces of the blood pressure, thus retaining fluids in the blood stream. In the equilibrium between cells and serum, however, the unequal distribution of protein is compensated by impermeability to other substances, especially the cations, sodium, potassium, calcium and magnesium. A 150 millimolar solution of sodium chloride has the same effective osmotic pressure as serum and as the contents of the red blood cells, that is, it contains per unit of water

the same concentration of osmotically active units that are restrained from crossing the cell membrane.

A series of experiments have proved that under certain standard conditions the human red blood cells are quite impermeable to the bases sodium, potassium, calcium and magnesium, and that, when the concentrations of base in the serum are changed, the cells give up or take on water in such proportions that the osmotic pressures in the two mediums always remain identical. The size and water content of these cells would seem to be entirely at the mercy of the serum in which they are bathed. These conclusions were verified by *in vitro* and *in vivo* experiments.

In the *in vitro* experiments it was also proved by direct analysis that no base passed into or out of the cells. In the *in vivo* experiments, however, when the same techniques were applied, unmistakable changes in the base of cells were detected. These findings were made in the very experiments in which changes of cell water and analyses of serum gave no evidence of transfer of base. Such results seemed paradoxical.

Although there is slightly more total base in serum, the concentrations in cells and serum are sufficiently alike to give the impression that, in the cells as in the serum, inorganic salts are chiefly responsible for the effective osmotic pressure. If this is the case, since the osmotic pressure of both media is the same, the concentrations of base in cells and serum should vary directly. Such is not the case. While serum base varies within relatively narrow limits, cell base varies over a much larger range. Furthermore, there is no demonstrable correlation between the two. Therefore base cannot have as important an osmotic role in cells as it does in serum. Osmotic equilibrium can exist when the concentration of base is distinctly higher in the cells than in the serum. In this case a fraction of the base in the cells must be osmotically inactive (perhaps because it exists in non-ionized form). It appears that any variation of base in serum is attended by a proportional change of osmotic pressure, whereas the base of cells can vary within wide limits without affecting osmotic pressure. The contents of cells are complex and include substances which do not exist in serum, but which must exert osmotic pressure. Moreover, in the cell, metabolic processes cause continuous permutations and combinations of solutes. Were these processes not osmotically buffered by some mechanism, they would produce constant changes in the volume and water content of the cells. There must be some means by which cells can, in times of need, accumulate or eliminate stores of material without being forced to take on or to excrete, at the same time, excessive amounts of water.

Red cells cannot be as completely impervious to base as would be inferred from *in vitro* experiments, else they would be excluded from elements essential for their activities. The impermeability of the cell membrane may be only a facultative property. Although cells are found to be impervious to phosphate and other ions in the resting state, if they are studied at higher temperatures such as are encountered in the body and in which metabolic processes are allowed to proceed, phosphate and potassium pour out of the cell during the process of glycolysis. This process was found to be reversible and was not purely mechanical in nature, but definitely a part of the metabolic process.

The red blood cell, then, appears to be always in osmotic equilibrium with its environmental fluid, blood serum. It responds to changes of the concentration of base in serum by transferring water and thus changing its volume. Moreover, so long as it is in the resting state, it

BOOK REVIEWS

The Biology of Pneumococcus The bacteriological biochemical and immunological characters and activities of diplococcus pneumoniae Benjamin White. 799 pp New York The Commonwealth Fund, 1938 \$4.50

Occasionally a book appears which almost at once comes to be known as a standard work of reference. This extensive monograph on the pneumococcus by Dr. White and his collaborators will surely take its place among this class. With thoroughness and scholarly accuracy which could not be surpassed by the most laborious of the German scientific writers of the past, the senior author has read and re-read the significant literature on the subject, both old and new, and then in the light of his long experience has fashioned these multitudinous fragments into a lucid and critical account of the various aspects of what he most accurately characterizes as this amazing cell.

In the beginning there is an interesting statement of the early history of studies concerning the pneumococcus. In reading it, once again we are filled with respect and admiration for the pioneers who brought order and light to the chaos and darkness that confronted them. During the last quarter of the nineteenth century the etiological role of the pneumococcus in most cases of lobar pneumonia was definitely established—not by any means a simple demonstration when we consider the variegated flora encountered in sputa and the difficulty, now hardly overcome, of producing experimentally the disease in anything like its natural manifestations. By this time, too, many of the fundamental facts concerning the cultivation, identification and antigenic attributes of the pneumococci were recorded. It is chastening to consider that much of the work of the past thirty-eight years has consisted in widening and leveling the paths which Pasteur, Fränkel, Denys, Mennes, Metchnikoff and others had so unerringly demarcated. In the following chapters, each of which may be regarded as a compendious though nonetheless comprehensive monograph on its specific subject, the authors treat of the biologic characteristics of the pneumococci, their classification, dissociative phases, degrees of pathogenicity for man and animals, and their chemical composition, especially in respect to antigenic structure. The final pages deal with the complex factors involved in the resistance of the animal body to infection with these microorganisms. Here we are given along with what is known concerning the mechanisms of pneumococcal immunity, practical information concerning the technics of active immunization by means of vaccines, as well as the most recent methods of producing efficient antisera to be used in the treatment of lobar pneumonia. After a brief account of the rationale of specific therapy and an assay of the results which have been obtained in the clinic through

active potassium and suggests that removal of the adrenals gives rise to a widespread derangement of cellular metabolism. Adrenalectomized dogs are benefited by restriction of potassium in the diet and can be thrown into shock by administration of potassium salts. This is consistent with the hypothesis that the intrinsic potassium of the cells is affected by the supply of inorganic potassium in the interstitial fluid. Observations upon a case of Addison's disease indicated that potassium became more concentrated in the cells and showed that water and electrolytes moved in the directions indicated by the previously cited experiments.

Depletion of serum sodium is extremely common in clinical medicine. It is regularly encountered in the states of dehydration that result from severe vomiting, diarrhea or gastrointestinal fistulae, in diabetic acidosis, in water intoxication, in lobar pneumonia, in the terminal stages of nephritis and sometimes with no discoverable cause. It has been too generally assumed that in all these conditions, as well as in Addison's disease, depletion of base has the same quantitative and qualitative effects. Such is not the case, as is proved by the wide range of symptomatology associated with deficits of base and by the variability of the responses to restoration of the concentration of salt in the serum. Both the concentration of base in the interstitial fluids and the volumes of these fluids must be accurately measured if precise information is to be gained about the organism as an entity. In addition, the allocation of these fluids and solutes between the various compartments of the body cannot be neglected, since the animal organism is not homogeneous, and finally, the state and activity of these solutes are matters of no little importance.

NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

At the annual meeting of the New England Society of Physical Medicine, held at the Hotel Kenmore, Boston, on May 18, the following officers were elected: president, Dr. Hosea W. McAdoo, of Arlington, first vice president, Dr. George B. Carr, of Lynn, second vice president, Dr. Henry A. Tadgell, of Wrentham, secretary, Dr. William D. McFee, of Boston, treasurer, Dr. Howard Moore, of Boston, councilors for three years, Dr. David T. Percy, of Arlington, and Dr. Charles W. Bruninghaus, of Worcester. Dr. Kristian G. Hansson, director of physical therapy, Cornell Medical Center, New York City, spoke on "After-care of Poliomyelitis." The paper was discussed by Dr. William T. Green.

NOTICES

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, June 21, at 12 o'clock noon.

Dr. Edward J. O'Brien will speak on "Twenty five Years' Experience with Obstructing Prostates," the talk will be illustrated with moving pictures of a transurethral resection of the prostate gland.

LAWRENCE CANCER CLINIC

The regular Lawrence Cancer Clinic, to be held at the Lawrence General Hospital, 1 Garden Street, Lawrence, on

Tuesday, June 21, at 10 00 a. m., will be a demonstration and teaching clinic for physicians, with Dr. Channing C. Simmons present as consultant. Physicians of the north half of Essex County are invited to accompany any of their patients whom they desire to have this service or to send them with a note. A report will be returned to every physician who sends a patient. The service is gratis. Any physician is welcome to attend the clinic.

This clinic is endorsed by the Committee on Postgraduate Instruction of the Massachusetts Medical Society.

ROY V. BAKETEL, M.D.,
CHARLES J. BURGESS, M.D.,
JOHN J. MCARDLE, M.D.,
HARRY H. NEVERS, M.D.,
THOMAS V. UNIAC, M.D.,
J. FORREST BURNHAM, M.D., *Chairman*

NEW ENGLAND HEART ASSOCIATION

There will be a special meeting of the New England Heart Association in the Ether Dome at the Massachusetts General Hospital, Wednesday, June 22, at 8 15 p. m.

Dr. George W. Pickering, from the Department of Clinical Research, University College Hospital, London, England, will speak on "The Problem of High Blood Pressure in Man."

Interested physicians and medical students are cordially invited to attend.

EDWARD F. BLAND, M.D., *Secretary*

NUMBER 24

OBSERVATIONS OF A RURAL HEALTH WORKER

ANDRIJA STAMPAR, M.D.*

IT IS a great honor your university has bestowed upon me, in appointing me Cutter Lecturer for the current academic year. I wish to express to you my profound appreciation for the compliment you pay me in asking me to address you.

The title I have selected for my lecture is "Observations of a Rural Health Worker." There are several reasons for my choice, personal as well as general. During the past years I was connected with rural health work, either as a director of health in a rural country, or as a fieldworker in rural districts. The first country in which I was employed was Yugoslavia, and the second, the largest rural country in the world, China. Being connected also with the international health service conducted by the League of Nations, I visited a large number of countries, undertaking a series of studies, in particular on the problems of rural health.

While I was trying to carry out some of my assignments I was confronted with the problems of rural life, and I found that successful results in rural health work depend on a number of factors usually considered to be outside a physician's province.

* * *

In recent years, in every country there has been a growing consciousness of the significance and importance of rural health. Each country has its own traditions, its own changing economic and social situations, which leave their mark on the development of public health, and it is therefore impossible to recommend one system for all. There is, I think, one point on which all are agreed, namely, that arrangements for the care of the health of the great masses of peasants in nearly every country are still far from adequate, and that this question has given rise to the important problem of public health, which has become increasingly more urgent with the existing rural distress. The

The Cutter Lecture delivered at the Harvard Medical School, Boston, February 15, 1938.

Formerly director of health of Yugoslavia and expert on health matters for the League of Nations Health Section.

practical application of our knowledge in public health is difficult in rural districts. In countries where the population is mostly agricultural, we may find excellent health activities in the urban districts, but there is usually a lack of physicians and health services in rural districts. It is commonly known that the death rate is higher in rural than in urban and industrial districts, and that the occurrence of infectious diseases is also higher. Some decades ago rural districts were healthier in comparison with urban. Now, the discoveries and experiences in public health are better applied and carried out in urban and industrial areas.

The vitally important need for health workers in rural areas is universally recognized. There are still enormous rural areas in the world without any proper medical aid, and without any preventive work. Even in the countries which have produced certain important results in public-health work there are still rural districts entirely neglected from the standpoint of health. The distribution of physicians is not made according to the needs of the total population, only a small percentage of them live in rural districts. The same can be said about auxiliary personnel. An illuminating study conducted by Dr. Kacprzak in Poland, in regard to the distribution of the physicians in 105 districts out of a total 241, shows that in the urban areas there was one physician for 1394 inhabitants and in the rural areas one for 21,414. In the villages only about 40 per cent of the deaths were certified by a physician, and only 30 per cent of the confinements were attended by a trained midwife. Similar facts have been pointed out by Dr. Stoichia in Roumania, where in rural districts only 35 per cent of the deliveries were attended by a qualified midwife. While in the urban areas 65 per cent of the confinements take place in hospitals or maternity homes, in rural districts this percentage amounts to only 1.2. In 1935, in the villages, only 22.4 per cent of the

its use, the text concludes with a statement of unsolved problems

The appendix includes descriptions of the laboratory procedures employed in the bacteriological and serological study of the pneumococcus and in the preparation of antiserums, and finally an admirably arranged bibliography of nearly sixteen hundred items which cannot fail to become indispensable to both student and investigator alike.

In wholeheartedly recommending this book to all who have any concern with these organisms and their effects, the reviewer cannot refrain from expressing his regret that Dr White could not have lived to see his excellent treatise accorded those honors which it so manifestly deserves

Lebens Versicherungs Medizin Felix Deutsch and Fritz Stern 282 pp Vienna Emil M Engel, 1938

Life insurance medicine, as a systematic and comprehensive study of the ratings of extra mortality (substandard risks), has very seldom been treated in a form which could justifiably be called a *book of reference*. In the book which has just been published, the authors have fulfilled precisely this *practical* requirement.

Medical directors and examining physicians of life insurance companies will find in this book an indispensable aid for their daily work. Medical advisers will gain from it the necessary comprehension of the theoretical basis and the practical requirements of their practice as life insurance physicians, which is often not their main professional activity.

In addition to this, the book gives a systematic insight into a medical field whose importance for medicine—considering the high place of life insurance in the entire economic sphere—is not always fully realized by physicians. In order to show the doctor who is not familiar with life insurance medicine its connections with general medicine, the authors have covered the clinical as well as the statistical point of view.

The introduction contains the following remarks:

It is obvious that the ratings found in this book will not be primarily new ones, it was frequently necessary to use standard ratings which are already known. Nevertheless we have given new ratings for a considerable number of symptoms and diseases and have also attempted to establish ratings for impairments which have seldom or never before been rated. Finally, we have sought to describe and classify the impairments for which we have given ratings on the basis of recognized clinical findings. We have, moreover, supplemented the section on insurance medicine by a description of the applicable methods of examination and by a list of occupational and athletic hazards, as well as by an attempt to give ratings for the additional risks (supplementary insurance for invalidism and accidental death).

We believe that the essential quality of this book consists in the following features: (1) that all fields of medicine, insofar as they have any relation to insurance medicine, have been covered, (2) that the systematic classification and revision of the material have permitted us to discuss all combinations and bases of clinical symptoms which are important for insurance medicine, (3) that we have ventured to give definite standard ratings, in order to create a uniform objective basis for the premium, excluding all subjective interpretations, as a starting point for further investigations in this field, and (4) that, in order to advance insurance medicine as

a science, we have considered it necessary to dispense with the reticence which has formerly been maintained in the publication of standard ratings, and we have thus made the rating of substandard risks a subject for detailed discussion.

Lectures on the Epidemiology and Control of Syphilis, Tuberculosis and Whooping Cough and Other Aspects of Infectious Disease Thorvald Madsen. The Abraham Flexner Lectures Series No 5 216 pp Baltimore The Williams & Wilkins Company, 1937 \$3 00

This is a book of two hundred pages, containing the fifth series of the Abraham Flexner Lectures, given by Dr Madsen at Vanderbilt University in March, 1937. It is the sort of material the reviewer at first thought he would skim through lightly, but he found himself held to reading Dr Madsen's lectures page by page and line by line.

Five subjects are dealt with as follows: Control of Venereal Disease in Denmark, with Special Reference to Syphilis; "Mechanism of Bacterial Infection"; "Tuberculosis in Denmark"; "The Influence of Seasons on Infection"; "Whooping Cough."

The reader is impressed with the advanced social organization and unity of Denmark. This comes to the surface in many ways. Tuberculous cattle were killed and paid for by the government before the turn of the century, the first tuberculosis seals were sold there in 1904, and we are reminded of the contributions of Finsen and other famous Danes.

Dr Madsen is more than a public health worker, to the reviewer it seemed as though physiology was his basic interest, yet nowhere within this volume does he deal with essential physiological subjects.

The book is an entertaining little volume and the material contained within must have formed an interesting group of lectures.

How Ancient Healing Governs Modern Therapeutics: The contribution of Hellenic science to modern medicine and scientific progress Kleanthes A Ligeros 523 pp New York and London G P Putnam's Sons, 1937 \$10 00

One would look far to find a drearier book than this. The author takes a deal of space to prove what requires no proving, namely, that much that is most worth while in modern thought and civilization had its roots in ancient Hellas. To assume as he does, however, that practically every important measure used in treating the sick was possessed by the Greeks is a manifest absurdity. As to Hellenic concepts actually governing modern therapeutics, his real complaint is that a good many procedures which the Greeks thought valuable have been discarded by the medical profession, in particular chiropraxis or manipulation of the spine.

But a fallacious thesis is not all that is the matter. There is a dearth of information from original sources, and even what is furnished is not entirely apropos. Nor, unfortunately, has Dr Ligeros any gifts as a writer. He is wordy, repetitious and prosy, and still worse, is given to unsubstantiated statements, and careless about the names of those he quotes and in his proofreading. Thus *empyema* is repeatedly "empyemia." And since when did the fallopian tube lead from the pharynx to the ear?

parts of Yugoslavia shows that the percentage of small holdings increased by ten from 1850 to 1936. In the period before the land reform was carried out this increase was even larger. With the growth of the rural population the number of the land-hungry peasants increased from year to year. The only means of relief was to reclaim the land and to enlarge the area for cultivation. As this work had generally not been undertaken on a large scale, there began a rural exodus and emigration to overseas countries and to newly industrialized regions. As emigration became more and more difficult during the last two decades, and more recently became practically impossible, distress in a large number of rural countries has even deepened.

In the past century urbanization and industrialization have gradually taken place in western European countries. The German urban population in 1871 was 14,800,000 and the rural population 26,300,000. In 1910 the urban population amounted to 39,000,000 and the rural to 25,900,000. In England in 1851 half the population lived in the cities and half in rural districts. Eighty years later, only 20 per cent of the population inhabited rural areas. In Belgium the number of the persons actively engaged in agriculture has decreased considerably in recent decades—from 25 per cent of the total population in 1846 to 8.2 per cent in 1930. In France from 1921 to 1931 the rural population decreased by 15 per cent. An urban and industrial Europe has come into existence.

The following facts give a picture of the agrarian situation in countries in which a large part of the population is engaged in agriculture.

In Poland there are 3,300,000 farms, the size of which varies widely. According to the census of 1921, two thirds of these farms were under ten acres and occupied only 25 per cent of the total arable land, while 19,000 farms were over 200 acres and occupied 27 per cent of the arable land.

In Yugoslavia, of 15,000,000 inhabitants 11,500,000 make their living from agriculture. Ninety-five per cent of all peasant families possess less than half and 5 per cent a little over half of the area under cultivation. Almost 20 per cent of the rural population possess no land at all, their income being derived from agricultural labor. Bulgaria is also a land of small farms. About 65 per cent of the land holdings are from five to twelve acres, occupying altogether six tenths of the arable land.

In Hungary, according to the 1930 census, 1644 land proprietors had holdings larger than a thousand acres, 10.1 per cent of all proprietors owned 148 per cent of the land and 779,105 proprietors held not more than two and a half acres, while 59.9 per cent of all proprietors owned only 4.3 per

cent of the total arable land. The number of laborers who were entirely landless amounted to a quarter of the total population. One third of them possessed their own cottages with small gardens. They earned low wages, which were in general below those earned before the World War. According to recent data, 55 per cent of the agricultural laborers were unemployed in the winter months of 1932-33, the average length of employment was 130 days, or barely 45 per cent of the potential annual working time. About 500,000 of these workers were not even employed during the summer.

In Roumania, 2,500,000 of the 3,300,000 farms comprise holdings below ten acres.

In Italy, one quarter of all the farms contain about one acre, 2,760,000 farms below eight acres occupy eight million acres, and 1596 large holdings comprise an area of ten million acres of arable land.

In Spain, the landed aristocracy, representing only 1 per cent of the total population, possesses more than half the total area of cultivable land. Three years ago, 3,000,000 of the 5,000,000 families engaged in agriculture possessed so little and so poor land that their standard of life was no better than that of the agricultural laborers. The large estates were worked by these landless laborers, whose earnings were very low.

In Far Eastern countries also, the rural situation is disquieting. The rural distress in India is shown by the rapid increase of domestic servants recruited from the agricultural population—from 2,500,000 to 11,000,000 between 1921 and 1931. In the Punjab over 55 per cent of the cultivators till less than five acres. This amount is not higher in other parts of India. The Punjab is called the land of peasant proprietors, but about 60 per cent of the land is cultivated by tenants paying cash or crop rents. In the United Provinces and in Bengal this proportion is even higher. It is estimated that in the United Provinces about 56 per cent of all tenants and peasant proprietors possess undersized holdings. In the central plains of Siam 36 per cent of the farmers possess no land, in the north 27 per cent, in the south 14 per cent and in the northeast 15 per cent. In the most fertile irrigation districts nearly all the families are tenants. In China, big land proprietors, absentee landlords and officials, forming only 10 per cent of the population possess more than half the land under cultivation, and poor peasants tenants and agricultural laborers forming 65 per cent of the population possess only 15 per cent. A survey undertaken in some of the eastern and southern provinces showed an average holding of less than one to one and a half acres. In one of the

registered deaths were attended by a physician during the illness, in the urban districts this percentage was as high as 32. In the rural areas 89 out of 100 infant deaths were not seen by a physician, in the urban districts 48. Out of 8273 physicians registered at the Roumanian Chamber of Physicians, 7010 resided permanently in the cities, and 1263 in the villages. There was one physician for 508 inhabitants in urban districts and one for 12,297 in rural districts. In Bulgaria at the end of 1936 there were 2719 physicians. Of this number 579 lived in the villages and 2140 in the cities. Not more than 20 deliveries out of 100 were assisted by a trained midwife. In Yugoslavia the situation is very similar. Of a little over 5500 physicians, only 800 are working in rural areas. In Austria more than half the physicians reside in Vienna—one for every 373 inhabitants, but in the province of Burgenland, which has the most rural territory of all the Austrian provinces, there is one physician for 2325 persons. The number of Hungarian physicians amounts to 10,306, of whom 4543 reside in Budapest. The ratio for Budapest is one physician for 219 inhabitants, and in the villages one for 1730. There are at the present time not more than 3200 medical men in Turkey, with a population of over 16,000,000, and these are located mostly in the larger cities—1000 in Istanbul alone. In Greece there are about 6500 physicians, of whom 1800 reside in Athens-Piraeus, with a population of slightly over 800,000. Czechoslovakian industrial areas are provided with better health services than are the typical rural districts. In the Soviet Union the five-year plans have provided an increasing number of physicians and health institutions in the villages, but their number is insufficient. The status of the health services in the large and predominantly rural countries of the Far East is surprisingly inadequate. In China there are less than 10,000 physicians for more than 400,000,000 inhabitants.

Generally speaking, social security for the farming population does not exist. For the workers engaged in industry proper a series of social insurance schemes have been enacted, for the workers engaged in agricultural labor this has been done only on a limited scale. The population of the urban and industrial districts is not only benefiting from the services organized for the treatment of the sick and for the prevention of disease by social security schemes, but is also taking a larger share in the social and health services organized and maintained by public funds.

It is difficult to estimate the rural population of the world, because changes are occurring in the composition of the population in general. There

has been a large rural exodus in almost every country. The growth and rapid development of urban districts have been striking. In general the percentage of the rural population has decreased. Still, of the 2 billion people in the world, at least 1½ billion are living in rural districts, mainly engaged in agriculture and home industries.

This agricultural population has a long history. The tillers of the soil made their own history, which influenced the events of the world. Their social position underwent three most important influences: that of outright slavery, that of serfdom, and, beginning several decades ago, that of personal freedom. In the vast area in which the rural population lives there still exist conditions which make life hard and even insupportable.

For centuries, farmers have been fighting for the possession of their own land. This struggle is still under way. The Roman Empire was weakened by agrarian revolts. The uprisings of the farmers which have occurred in almost every century were the consequences of social and economic unrest. In the period from 1789 to 1870, the agrarian revolution in European countries gave peasants freedom but left them still economically dependent. In the period after the Franco-Prussian war, in most European countries land reforms were carried out. The large holdings were expropriated and divided among landless peasants and those owning small land holdings. New settlements were established for the former on the large holdings previously belonging to wealthy landlords. In the Far East, with the largest rural population in the world, amounting to nearly 1 billion, the social and economic status of the peasantry has not changed materially, being still semi-feudal in character. In China, rural distress caused agrarian revolts over a large part of its enormous area and resulted in the loss of millions of lives. In India, the second largest rural country, there still prevail conditions which are keeping farmers in extreme poverty. In Japan there occurred an impressive improvement in the cities and a large number of industrial establishments were built up, but the farming population has remained to work the land, which for the most part does not belong to them.

In Europe, after the great reforms in the nineteenth century land could be conveyed with freedom, and family ties were weakened. This has produced a phenomenon known as the pulverization of holdings. The process can be shown by a few examples. In Hungary small holdings, those under five acres, numbered little over 22,000 in 1851. The total rose to over 1,000,000 fifty years later. In the same period the number of agricultural workers doubled. A survey made in some

vestigations and activities. There are still millions of human beings whose health has never been properly cared for. There are still very many physicians graduated from the best medical schools with inadequate knowledge of the importance of rural health problems and rural conditions as well as the enormous possibilities for health work in rural areas.

* * *

Medical activity was formerly concerned mainly with the treatment of the sick. The best doctors attended only individual patients, and the services they provided were limited to a relatively small proportion of the population. The unequal economic conditions among patients have naturally had a detrimental effect on the relations between the doctor and the patient. Owing to the ever-increasing number of doctors, the practice of medicine is thus placed on a totally different basis.

The social side of medicine should not be neglected. This applies particularly to rural areas where social and economic conditions influence the whole rural life. This side of medicine is concerned with the problems of social ills and their origins and of social medicine. A rural health worker should bear in mind these aspects of medicine.

The social ills of rural areas are concerned with a large group of social problems of a medical kind such as bad housing, social diseases and malnutrition, which cannot be properly understood until their connection with social conditions is realized. Such investigations cannot be conducted in laboratories alone, but involve probing into every smallest part of the people's life and the closest scrutiny of the habits and customs and of the particular sections of the community.

The practice of social protection and prevention are showing ever more clearly that the medical man must make use of social science and that an acquaintance with it is essential to the success of his work. This leads to a change of approach in medical work, in this sense, that the physician applies his learning to the people as a whole, thus extending his knowledge and becoming a physician of the whole community. With the experience thus gained and the skill developed by practice, the medical man learns to feel the pulse, not merely of the single patient but of the nation as a whole, to study pathologic phenomena, not only in the lecture rooms and laboratories of institutes and in hospitals but on the body of whole sections of society, and indeed of the nation as a whole.

Whereas doctors were usually regarded as representatives of a purely humanitarian work, their activities, viewed from this angle, have made them

factors in economic life. Ruskin rightly defined the true aim of national economy as "the producing of as many as possible full-breathed, light-eyed and happy human creatures."

The importance of education on matters of public health should be specially emphasized.

The problems of public health do not fall exclusively within the province of the activities of a medical man, for health is our common heritage. The people's minds must be prepared for the measures to be applied, so that they can understand them and contribute to their enforcement. A law, however excellent, cannot be properly carried out, can yield only very poor results, if it finds no support among the people. This conception of education as a part of preparatory work for health activities shows most clearly how the physician should be a teacher of the people, indeed, he should make the greatest possible use of education as the best and surest way to success.

If we turn our attention to the problems of rural health, we can readily realize the importance of such a work in this field, for many of these problems can be solved by the methods mentioned above.

Medical activity is changing. Out of the physician who looked after and cured an individual there has developed the physician who looks after the health of a whole society. This development in the medical calling is a logical result of the growth of preventive medicine. It has led the physician out of the consulting room into society to contribute his full share to the health of the whole world.

It is usually assumed that the peasant is primitive and conservative, and that in his case health work encounters great difficulties. This conception, however, is due only to insufficient knowledge of the peasant's life. Our training usually takes us far from ordinary rural life, even in the case of persons of peasant origin. Peasant life nevertheless contains all the elements required for every form of progress. Generally speaking people have not bothered much about the peasant, as he is always looked upon as a permanent source of new life and reinvigoration in every nation. Yet in the villages, among the peasants, spiritual life can be found in abundance by those who would seek it out.

Are not the famous national songs and costumes the best indication of an exceptional spiritual life? Have not many famous men sprung straight from the peasantry? Sensitive to many fine features of peasant life, writers of genius have described them in some of the great masterpieces of literature. My happiest memories are those of life among the peasants. During my last period of

most fertile provinces in the south, two thirds of the farmers were living on one third of the land. In the most densely populated area of China, south of the Yellow River, tenancy is the most common form of land tenure. On the average, the tenant farmer pays about one half the proceeds from his crop to the land proprietors. In rural Japan feudal conditions still prevail. Sixteen per cent of the cultivable land is in the hands of the big landlords. With very few exceptions they rent their land to the poor and landless farmers. Half the total number of land holdings are composed of farms averaging less than two and a half acres in extent and comprise a little over 8 per cent of the total area under cultivation. The same area is owned by the big landlords, who possess over 120 acres each, but the number of their holdings amounts to only 0.1 per cent of the total. Of every 100 farmers, 74 are tenants or part-tenants and small owners.

The history and influence of the large landed properties or haciendas on rural life in Central and South American countries is too well known to be described here. The distress of the peasantry and agricultural workers caused by them is common knowledge, as are the resulting disturbances, which affected the whole rural life of some states. Of this, Mexico is an example. There are very large holdings amounting sometimes to two hundred and fifty thousand acres. The land is cultivated by the workers, who are bound to haciendas. This system has left some 5,000,000 of the population without agricultural holdings. They are laborers on the large farms, earning very low wages. In Chile the large estates of over two thousand acres, 18 per cent of the total number, cover nearly 80 per cent of the arable land. The living conditions of the agricultural workers are deplorable.

The rural areas are supplying cities and industrial districts with cheap labor and foodstuffs. The standard of life in the urban and industrial regions has improved very rapidly, while progress in the rural districts has been very slow. A large amount of agricultural products are exported from rural countries, and this is sometimes considered as a sign of prosperity in these regions. A survey undertaken in several rural countries on the nutritional status of the population showed that there exists undernourishment among a large number of the rural population, and that agricultural products are exported from rural countries without consideration of the nutritional requirements of the people. The reasons are purely commercial. The industrial products imported into the rural countries in exchange serve mainly the urban population and industrial establishments, from which

the farming population derives comparatively very small benefit. To cover their money requirements the farmers owning small holdings are usually compelled to sell the best products of their farms to the town people. Thus they are helping the cities and industry, themselves remaining far in the rear in regard to sanitation, housing, health and general education.

The unfavorable social and economic conditions of a very large part of the rural population, which have been pointed out here only in a general way, were followed by other phenomena such as illiteracy, illness, a high general and infant death rate, poverty, unrest and migration, the time allowed for this lecture is too limited to permit describing them in every detail.

* * *

When I was reviewing the rural conditions all over the world I thought about the rural health workers who are confronted with this situation. I am thinking now about medical officers who have initiated and are directing and stimulating health work in rural areas. The primary duty of a physician in a rural district was for a long time considered to be to serve as a helper to the sick. My own experiences have led me to believe that a health worker in a rural country must go much farther, and that his service must be connected with a scheme of general rural reform. His work when isolated is bound to fail. After working for some years in my native country and in China I came to the conclusion that successful health work is not possible in areas where the standard of living falls below the level of tolerable existence. The removal of social grievances, such as the sense of exploitation by others, is of the greatest importance. For social and health services depend for their success on the co-operation of the people, and this will only be given by a population which is reasonably optimistic concerning the future, and which is willing to give at least qualified acceptance of the social order.

After these general remarks I should like to make some observations in regard to the role of a physician in a rural country. I am thinking here mainly about the health officer, whose duty is to lead and to create. Obviously he is confronted with a much more difficult task than is a medical officer of an urban or industrial area. The rural conditions are still not sufficiently known, and for this reason the work of such a health officer is more difficult and cannot always be carried out on the usual pattern. In rural areas there is plenty of room for new starts and for very illuminating studies. The vast rural districts, which have never been properly covered by medical men, give a special opportunity for a wide field of health in-

vestigations and activities. There are still millions of human beings whose health has never been properly cared for. There are still very many physicians graduated from the best medical schools with inadequate knowledge of the importance of rural health problems and rural conditions as well as the enormous possibilities for health work in rural areas.

Whereas doctors were usually regarded as representatives of a purely humanitarian work, their activities, viewed from this angle, have made them

factors in economic life. Ruskin rightly defined the true aim of national economy as "the producing of as many as possible full-breathed, light-eyed and happy human creatures."

The importance of education on matters of public health should be specially emphasized.

The problems of public health do not fall exclusively within the province of the activities of a medical man, for health is our common heritage. The people's minds must be prepared for the measures to be applied, so that they can understand them and contribute to their enforcement. A law, however excellent, cannot be properly carried out, can yield only very poor results, if it finds no support among the people. This conception of education as a part of preparatory work for health activities shows most clearly how the physician should be a teacher of the people, indeed, he should make the greatest possible use of education as the best and surest way to success.

If we turn our attention to the problems of rural health, we can readily realize the importance of such a work in this field, for many of these problems can be solved by the methods mentioned above.

Medical activity is changing. Out of the physician who looked after and cured an individual there has developed the physician who looks after the health of a whole society. This development in the medical calling is a logical result of the growth of preventive medicine. It has led the physician out of the consulting room into society to contribute his full share to the health of the whole world.

It is usually assumed that the peasant is primitive and conservative, and that in his case health work encounters great difficulties. This conception, however, is due only to insufficient knowledge of the peasant's life. Our training usually takes us far from ordinary rural life, even in the case of persons of peasant origin. Peasant life nevertheless contains all the elements required for every form of progress. Generally speaking, people have not bothered much about the peasant, as he is always looked upon as a permanent source of new life and reinvigoration in every nation. Yet in the villages, among the peasants, spiritual life can be found in abundance by those who would seek it out.

Are not the famous national songs and costumes the best indication of an exceptional spiritual life? Have not many famous men sprung straight from the peasantry? Sensitive to many fine features of peasant life, writers of genius have described them in some of the great masterpieces of literature. My happiest memories are those of life among the peasants. During my last period of

activity my deepest impressions were those gained during the days I spent among the Chinese peasantry. The peasants in Yugoslavia have shown an extraordinary strength in their struggle for a better life. The *Croatian peasants are organizing* themselves socially and economically, preparing a basis for a better future. In their houses have been born writers who are active in every branch of public life. There is everywhere a strong movement among the peasants all over the world.

Thus a closer acquaintance with the peasant and a detailed study of conditions in rural districts are necessary before a plan of work can be mapped out. The peasant represents by far the largest component of the population in most countries, yet we know little and learn less about peasant life. Physicians often discuss the great incidence of mortality and disease among the peasantry, but these questions are not studied so thoroughly as they should be, particularly in the light of this consideration that health questions in rural districts can hardly be undertaken without a knowledge of general peasant standards.

Applied hygiene has before it a wide field of research into cultural, social, economic and health conditions in the rural environment. Some investigations have already been made on these lines in some countries, but they are isolated and disconnected in character. Moreover, the school and the home, manners and customs, cannot be separated from health. The physician should make it his first business to familiarize himself with peasant life from every angle, otherwise he will scarcely be in a position to organize appropriate health protection. The field of work must be known before systematic labor can begin.

Education is one of the most difficult problems in rural districts, but without it no progress in health work can be achieved. This work is sometimes regarded as an easy matter, but it calls for great skill, and requires a thorough knowledge of the region and of the people's minds. Overelaborate popular health education, undertaken without suitable preparation or a correct knowledge of conditions of life in the country, can occasionally do more harm than good. The educational activity of the village physician is necessary, if only to secure the collaboration of the population in health matters. As has already been pointed out, the whole population must participate in general health activities, for only thus can health-consciousness and the desire for health become general. The need for general collaboration must be particularly stressed in these times of economic depression, the health machinery in country districts can be planned by experts in the light of the latest experience and knowledge, but the practical work

must have the support of the population, and institutions for the protection of health must be set up by their help. Nothing is easier than to collaborate with peasants in the right way, they have great *resources of common sense and understanding, courage and strength*.

If the peasant in his struggle for existence has opened the wide spaces of the earth and drawn from them with his own hands the natural products on which the great cities live and flourish, why should he not sink wells, build water mains and erect health institutions? In the course of my long experience I have always found it easy to secure this co-operation, and I am more than ever convinced that the peasant is the best collaborator in health matters.

The most efficient method of health education in rural districts is the establishment of health activities, from which a peasant derives a direct benefit. Such a method is employed in Yugoslavia. The schools of public health and the institutes of hygiene are the centers of rural health activities. They advise farmers in sanitary engineering matters, conduct field work with their help, construct wells, latrines and manure pits and devise rehousing schemes on individual farms and establish central water supplies for whole villages. The schools and the institutes sometimes help with material for construction or with cheap loans, and the farmers contribute free labor. Such field work naturally stimulates an interest among the peasants. It creates a movement for better health among the rural population. In special classes during the winter the peasants are taught subjects of general educational value, but particularly those of agriculture, basic veterinary work, animal husbandry and health. The peasant women attend special courses in home economics, at which they are also instructed in health matters. Such methods show far better results than those of lecturing and exhibiting.

Nutrition in country districts has not been sufficiently investigated, so that here we are still largely on unexplored ground. Some people, thinking of the food the peasantry produce, wrongly assume that the peasant population has at all events enough to eat, but it is no exaggeration to affirm that in many districts the peasantry goes hungry, and that in even more districts the diet is unsuitable. Let the village physician devote a great deal of attention to this field of preventive medicine, for he can do much that is practical.

The value of the collaboration of the population in health matters has been sufficiently demonstrated. As has just been said, health work cannot be conducted actively in isolation, but must be accepted as part of the general work of rural reconstruction.

Purely medical activity cannot adequately promote the public health, since health problems depend for their solution on educational, economic and social factors which exert a decisive influence in most cases of disease. In country districts complete success by the physician is only to be expected if his activities are combined with those of the schoolteacher, the agricultural expert, the veterinary surgeon and the engineer.

The prevention and control of animal diseases is particularly important. The occurrence of infectious diseases among animals in rural areas is very high, and the losses are sometimes disastrous to rural economy, causing additional distress and poverty. The combined activity of a physician and veterinary surgeon in the village is very welcome to the farmers. They are most interested in health work if economic advantage follows it. In a remote part of China, in which animal husbandry plays an important role in rural life, the health services recently organized have been combined with services for the protection of animal health. The agricultural experts can introduce a better method of cultivation, and raise the yield per unit and thus also the standard of living. Engineers can reclaim, protect and increase the area of the arable land. Some data concerning Yugoslavia will clearly show to what extent such a work could improve the peasant life. In that country almost one quarter of the total population lives in regions which are too infertile to produce sufficient food. It is estimated that about one half this population must buy three quarters of the grain required for bread. The poverty in these regions sometimes prevents the people from buying necessary foodstuffs. Yet the area which is not under cultivation or not properly protected, and which could be made arable, is sufficiently large to provide the inhabitants with food, to raise the present low standard of living and to improve rural health conditions.

The chief professional help must come from the public-health nurse, but she can be of genuine as-

sistance only if she works on the same principles. She must act as a helper and teacher to the peasant population. It should be emphasized that to do her work aright and to be successful, the nurse must have been trained in the right way. Specialist training in various branches of health work would, however, be uneconomic and unsuitable in rural districts.

* * *

The tasks we have described naturally require a new outlook on the part of the medical profession, the spirit of the times and the even more manifest health needs of the peasant population compel us to think and work differently as time goes on.

There are several reasons for the maldistribution of physicians, medical aid and preventive work in the rural districts. Naturally the factors of economic nature are of primary importance. As long as a health worker cannot make an adequate living out of rural health work there will be a general lack of physicians in rural areas. Educational factors are also playing an important role. Villages are generally considered to be an unsuitable field for medical activities. Effective rural health work requires certain changes in medical education, particularly in regard to the social aspects of medicine. The other important factors should not be overlooked. The social and economic conditions of the rural population are in general such that they require a profound change. We reached the conclusion long ago that economics and health are interdependent, and this fact applies especially to rural areas. Successful health work can be attained only if it is correlated with other activities for the improvement of rural life. This naturally depends on a successful collaboration of the people and their free participation in public affairs. A rural health worker must therefore be a promoter of a social, political and economic peace. For these factors are fundamental requisites to the success of rural health work.

THE LOCALIZATION OF INTRACRANIAL LESIONS BY ELECTROENCEPHALOGRAPHY

DENIS WILLIAMS, M.D., M.R.C.P.,* LONDON, ENGLAND, AND FREDERIC A. GIBBS, M.D.†

BOSTON

NEUROSURGEONS have been greatly handicapped in their operative approach to intracranial lesions such as tumors and abscesses by difficulty in localizing the lesions. The most skillful neurological examination succeeds in doing so only in a minority of cases, and every clinical neurologist has from time to time found it impossible to decide whether symptoms of high intracranial pressure are caused by a frontal tumor or by an obstructive lesion of the posterior fossa. Study of the chemistry and hydrodynamics of the cerebrospinal fluid may facilitate the interpretation of clinical observations, and auxiliary methods employing radiography—encephalography, ventriculography and arteriography—have played an increasingly important part in the diagnosis of these lesions. The routine use of such radical diagnostic procedures in these cases reflects the difficulty which the clinical neurologist encounters in establishing accurate diagnoses.

The limitations of the available methods of investigation of neurologic disorders, especially those involving the central nervous system, render any additional diagnostic procedure of particular value to the clinician. Should this method enable the neurosurgeon to plan his operation with greater certainty and safety, it would have great practical value and earn an established place in clinical investigation.

That such a procedure is available was shown by Grey Walter⁴ in 1937, for he proved that electroencephalography affords a technic for the localization of intracranial lesions which has a high degree of accuracy without involving any discomfort or danger to the patient. He had observed³ that a focus of abnormally slow electrical waves collected from the intact cranium coincided with an area of cortical involvement by gliomatous tissue. Later⁴ he predicted the position of cortical damage in 12 cases in which tumor was subsequently seen. He showed that the slow waves occurred in poorly functioning cortex. In 26 cases with normal cortical potentials and in which a cerebral tumor had been suspected on clinical grounds, the subsequent investigation and progress of the cases showed that none had been present. It appeared, therefore,

that the method had very great practical application.

Walter developed his technic as a modification of that described by Adrian and Matthews.¹ With pads moistened in salt solution and placed on the scalp, he led off and amplified the minute changes in electrical potential—of the order of 1/50,000 of a volt—which are produced by the brain. He recorded these with a cathode ray oscillograph on moving bromide paper. With three pairs of electrodes connected to three separate amplifying and recording units, he was able, by noting the amount of abnormal activity in the three records and the phase relation of the abnormal slow waves, to determine which electrode was immediately over the focus of discharge (Fig 1). By moving the electrodes he determined the size and shape of the focus.

In order more fully to ascertain the value of this method to clinicians it seemed desirable that it should be tested independently on a random sample of patients under the conditions of ordinary hospital practice. This we have done, using the technic described by Walter, the only difference being that the oscillograph records were made with an ink-writing instead of with a cathode-ray oscillograph.

RESULTS

Most of the patients were referred from the Neurological and Neurosurgical Units of the Boston City Hospital. We are indebted to Dr. Donald Munro, Dr. Walter Wegner and Dr. Tracy Putnam for their co-operation in this investigation. A few patients in whom the diagnosis was obscure and to whom it was thought that electroencephalography might be of value were referred from other hospitals. So far as possible all the cases were examined in ignorance of the history or clinical findings, and clinical reports were not obtained until a report had been given on the electroencephalogram.

Eighty patients were examined, of whom 50 had abnormal cortical potentials with evidence of focal disturbance. Seventeen patients showed no cortical abnormality, and 13 had records characteristic of epilepsy, without any evidence of a constant focus of discharge of slow waves.

In 13 of the 50 cases with focus of abnormal

discharge operation was not performed, and the clinical diagnosis was too indefinite to verify the accuracy of the observations. In these cases it was impossible to discover whether the focus corresponded with the position of the organic lesion.

In the remaining 37 cases verification of the position of the abnormality was possible. In 22 the lesion was seen at operation or autopsy, in 10 its position was established by unequivocal clinical findings, confirmed in 4 by radiological evidence, and in 5 a bone defect was present in the skull

cerebral tumor was made. She was discharged, having refused operation.

She was readmitted in December, 1937, with symptoms of high intracranial pressure, failing vision and generalized grand mal seizures. There was bilateral papilledema with a hemorrhage on the right. The pupils were irregular. There was slight weakness of the left side of the face and weakness and unsteadiness of the left arm. The right upper abdominal reflex was absent. X-rays of the skull showed thinning of the floor of the sella and erosion of the posterior clinoids, but no evidence of a local lesion. A diagnosis of right parietal tumor was made.

Electroencephalography showed 'irregular slow activity

Figure 1 Records taken from the scalp of a patient with a left midparietal lesion. Three units are recording from the head. In the upper three tracings electrodes are placed in an anteroposterior position in the right hemisphere. A normal rhythm of about ten per second is seen. In the lower three tracings similar leads are used in the left hemisphere. Large slow waves of one or two per second are present in leads 1 and 2. The normal ten per-second rhythm is absent. The slow waves in lead 2 form a mirror image of those in lead 1, indicating that the focus of discharge is originating under the electrode which is common to leads 2 and 1.

as a result of previous trauma. In every one of these 37 cases the position of the single focus of abnormal discharge corresponded closely with the site of the organic lesion. For purposes of verification the 22 cases in which the cerebral lesion was seen were of greatest value. In these the correlation was striking. It would not be profitable to describe all the cases in detail. Instead, brief summaries illustrating the results in a few of them are recorded below.

CASE REPORTS

Case 1 F. G., a female aged 55, was admitted to the Boston City Hospital in May, 1935, complaining of left sided Jacksonian seizures. A diagnosis of right frontal

in all leads, with maximal and much more constant abnormal activity over the right parietal lobe. This is most marked rather low in the antero-parietal region. The diffuse waves may be due to increase in intracranial pressure.

At operation a right fronto-parietal osteoplastic flap was turned to center over the area of abnormal electrical discharge. A large meningioma was found in the center of the flap.

Case 2 J. R., a male aged 37, was admitted to the Boston City Hospital in October, 1937, having 1 year's history of a gradual onset of right sided sensory loss beginning in the hand and tongue and right sided focal seizures beginning in the fingers. Clinical examination showed slight signs of upper motor neurone damage in the right side, with moderate diminution of all forms of sensation of a hemiplegic type on that side. Encephalog

raphy showed slight convolitional atrophy in the right temporo-parietal region

By electroencephalography, "a normal rhythm was seen throughout, with the exception of a few low voltage slow waves emanating from the right temporo-occipital region, suggesting slight impairment of cortical activity in this region. If there is a lesion it is probably deep and is not involving the cortex directly." At operation an arterio-venous angioma was found in the posterior Sylvian region. A few veins presented at the surface, but it was obvious that most of the lesion lay beneath the surface of the cortex

Case 3 E. L., a male aged 63, was admitted to the Boston City Hospital in January, 1938. He had had headaches, nausea and vomiting for 2 months, diplopia for 1 month and drowsiness and mental deterioration for 2 weeks. On examination he was drowsy and apathetic, had a poor memory and was incontinent of urine. There was doubtful bilateral sixth nerve weakness, doubtful papilledema, and a suspicion of weakness on voluntary movement of the left side of the body. The tendon reflexes were equal, the right abdominal reflexes absent and the right plantar response equivocal. A tentative diagnosis of frontal tumor was made, the side being undetermined.

Electroencephalography showed 'very high voltage slow activity in the right frontal region extending as far back as the premotor area. There was slight abnormality on the left side, perhaps due to high intracranial pressure.' It was considered that there was very gross cortical dysfunction over the whole of the right frontal lobe. On ventriculography there was displacement of the right frontal horn, and at operation a hemorrhagic cyst the size of a tangerine was found in the right frontal pole 0.6 cm. below the surface. The overlying cortex was flattened and discolored.

The following case demonstrated the value of electroencephalography when clinical evidence of an intracranial lesion was lacking

Case 4 R. McK., a female aged 22, was admitted to the Boston City Hospital in October, 1937, having had frequent petit mal attacks for 2 years and four grand mal seizures in the last year. Except for a doubtful right sided onset, there were no localizing signs during the seizures. The only positive clinical signs were slight left sided motor weakness and a slight increase in the tendon jerks with an equivocal plantar response in the right. The visual fields were normal. X-rays of the skull showed no abnormality. A clinical diagnosis of 'epilepsy with a focus of undetermined nature in the left hemisphere' was made.

The report on the electroencephalogram was 'The left side appears normal. The right shows large waves with much abnormal activity centering in the posterior parietal region, with a central silent area. This abnormality is very widespread and suggests much cortical change.' From the type of disturbance it was thought that it might be due to a meningioma or some other destructive cortical lesion, and as the focus of discharge was so well marked, an encephalogram was strongly advised. This showed a large dilation of the temporal horn of the left ventricle, below the silent area localized by electroencephalography. A right parieto-occipital craniotomy was therefore performed, and a cyst 5 cm. in diameter was exposed in the right posterior parietal cortex. There was no overlying cortex, and the cyst communicated with the temporal horn of the right lateral ventricle, of which it was an enormous dilation. The cyst corresponded with the silent area in the abnormal discharge recorded electrically, and it

was seen that the occipital pole, from which normal waves had been obtained, was unaffected by the lesion

In 1 case where two lesions were found at autopsy, only the major lesion had been recognized by elec-

Figure 2 Charts of the cerebral hemispheres of 3 patients in whom the lesion was seen at operation. On the left is shown the position of the lesion as drawn by the neurosurgeon after the operation. On the right is the position of the focus of abnormal activity, as drawn on the report sheet given to the neurosurgeon before the operation

troencephalography. The patient was in deep coma and had high intracranial pressure at the time of investigation, and an enormous area of pathologic high-voltage discharge was maximal in the right temporo-parietal region. At autopsy, a large, wedge-shaped area of ischemic necrosis was found

to coincide with this discharge, and a meningioma was present on the outer and lower aspect of the left frontal lobe. Subsequent examination of the record showed that a subsidiary focus was present in this region also. In 2 of the cases presenting two foci of abnormality, the position of the greater disturbance only had been verified but the possibility of multiple foci was great.

In 6 cases where a lesion was subsequently seen to coincide with a focus of abnormal electrical discharge, it had been impossible to localize the lesion by clinical methods or by x-rays of the skull, three of these which subsequently came to autopsy, were considered to be in too precarious a condition to warrant encephalography. Electroencephalography was employed in all these cases. It was successful where all other available diagnostic methods had been found inadequate.

The lesions causing the abnormal discharge were diverse. They consisted of tumors (15 cases), abscesses (6 cases), traumatic lesions (6 cases), subdural hematomas (4 cases), porencephalic defects (2 cases), and Paget's disease of the skull causing localized cortical pressure, an idiopathic local cortical atrophy, Schilder's disease, and a tuberculoma (1 case each). This series of 37 cases, therefore, confirms Walter's observation that the slow waves emanate from abnormal cortex and not from the causal lesion. Foerster and Altenburger⁷ had previously shown that cerebral tumors were electrically inactive.

The negative cases in this investigation were also of interest, for in 7 a diagnosis of cerebral tumor or cerebral damage due to trauma was refuted by a normal electroencephalogram and the subsequent course of the cases suggested that this conclusion was correct. Total destruction or absence of cerebral cortex, unless gross, as in Case 4, may not be demonstrated by this method, especially if the remaining cortex is normal. This is illustrated by the following case.

Case 5 A G, a female aged 24, was admitted to the Boston City Hospital in September, 1937, with a recent bullet wound of the left occiput. The wound was explored the day after admission. The left occipital pole was lacerated, and fragments of bullet and bone extended along a wide track into the lateral horn of the left ventricle. All damaged brain tissue was excised, and a clean cerebral defect about 2 cm in diameter remained in the left occipital lobe. When discharged from the hospital the patient was well except for a complete right homonymous hemianopia.

Electroencephalography performed 6 weeks after the operation did not disclose any abnormally slow activity from the left occiput.

It is therefore apparent that a cortical defect is not responsible per se for the abnormal frequencies recorded. When we correlate the types of activity

occurring in the neighborhood of cerebral lesions, it appears that abnormal slow waves are most evident in diffuse cortical lesions where prolonged cortical damage short of complete cell destruction is present. Such situations are found at the periphery of large meningiomas, in cortex which is being infiltrated by gliomas, in the edematous cortex overlying an abscess, and in progressive idiopathic cortical degeneration. Thus by correlating the frequency and amplitude of the pathologic waves with the position of the discharge and its extent, it is possible in some cases to surmise the nature of the lesion. When the type of electroencephalographic record is correlated with the history of the illness and the clinical manifestations of the lesion, the method may be of considerable value to the physician in assessing the nature as well as the position of the lesion.

It has been shown that many destructive cerebral lesions cause abnormally slow cortical waves. High intracranial pressure gives rise to similar slow waves which are widespread throughout the cortex. When hypertonic intravenous glucose saline is given, however, the generalized slow frequencies can be eliminated and an underlying focus of activity determined. In 1 case in this series with high intracranial pressure, after hypertonic glucose had been administered intravenously it was found that no local cortical discharge was associated with the high pressure. A clinical diagnosis had not previously been made, and as a result of the electroencephalographic report a posterior fossa decompression was performed and a tumor exposed. There is no evidence, however, that lesions in the posterior fossa can be localized by this method, and the depth of overlying tissue, combined with the difference in electrical behavior of the hind brain, makes the application of the method to such lesions of extremely doubtful value.

The results of this investigation of 80 cases confirm Walter's observation that in electroencephalography an adequate method for the localization of intracranial lesions is available.

SUMMARY

Eighty patients from a neurological and neurosurgical service suspected of intracranial lesions were investigated by electroencephalography, using a method described by Walter.

In 50 cases a focus of abnormal activity was found. In 37 of these the position of an organic lesion was established. In every verified case the position of the lesion coincided with the area of electrically abnormal cortex. In 1 case with two lesions, only the major lesion was demonstrated.

In 6 cases it had not been possible to localize the lesion, which was demonstrated by electroencephalography and subsequently exposed surgi-

cally, by any other method, and in 7 cases a negative diagnosis in the face of clinical evidence to the contrary was subsequently shown to be correct.

The results have been elaborated and their significance discussed. It is concluded that this technique is of considerable value in the diagnosis of intracranial lesions.

OBSERVATIONS ON THE CONVULSANT TREATMENT OF SCHIZOPHRENIA WITH METRAZOL

A Report of Seven Cases

LOUIS H. COHEN, M.D.*

WORCESTER, MASSACHUSETTS

WITHIN the last few years there has been added to the armamentarium of the clinical psychiatrist the irritant or convulsant treatment of psychosis, particularly of schizophrenia. This form of treatment was first proposed by von Meduna,⁶ and is now being carried out in an increasing number of clinics in America and abroad. It is the purpose of this report to summarize the principal features of this treatment, and its application in 7 patients with schizophrenia, for it is in the latter disease that it has found its most extensive and promising application.

The treatment consists essentially of the induction of a series of convulsive seizures by the use of drugs, particularly metrazol, in dosages appropriate to the individual case. Although at first sight such treatment appears somewhat heroic, its worth as shown by the present data cannot be gainsaid, and to date very few ill effects have been reported.[†]

From data reported by various investigators, considerable optimism with respect to this form of treatment has been aroused. In von Meduna's⁶ series of 110 patients, 54 patients underwent remissions and 56 remained unchanged. In Wahlmann's¹⁰ series of 20 patients (including one manic-depressive who recovered), there occurred remissions in 8 patients and no change in 12. In Friedman's² series of 40 patients, 32 improved or had remissions. Nyirö⁷ observed improvement or complete remission in 13 of 24 patients. Scheuhammer and Wissgott⁸ have reported a series of 41 patients, 30 of

whom have completed the course of treatment, in 13 cases complete or almost complete remissions were obtained. The results were best in the catatonic and paranoid-hallucinatory patients and worst in the hebephrenic.

These writers consider the duration of the disease to be of definite prognostic significance. In 13 patients in whom the disease had lasted for one and a half years or less, the remission rate was 69 per cent, whereas in the 17 other patients, in whom the disease had been of longer duration, only 4 remissions were obtained. Of the patients with remissions, 5 have been continuously well for four or five months. Von Meduna⁶ maintains that in patients who have been ill not more than six months the remission rate is from 80 to 90 per cent, this rate falls rapidly after the illness has been present for a year, and in cases of longer than four years' duration is practically nil. Sorger and Hofmann,⁹ in their series of 100 patients, have reported the following data, which also indicate clearly that the prognosis with this treatment is better the shorter the duration of the disease:

DURATION OF DISEASE	NO. OF CASES	REMISIONS		UNCHANGED	
		No.	%	No.	%
Acute (up to ½ yr.)	38	29	76	9	24
Subacute (up to 1 yr.)	13	7	54	6	46
Chronic (over 1 yr.)	49	13	27	36	73

It thus would appear that, even allowing for a certain tendency to spontaneous improvement, treatment by metrazol is of material advantage.

RATIONALE

On the basis of reports by various psychiatrists that schizophrenia and epilepsy are rarely if ever found together, and also that patients with frequent epileptic fits who had schizophrenic features recovered rapidly, von Meduna⁶ has postulated a biologic antagonism between these two disease processes. He has therefore maintained that by in-

†In a series of 110 patients observed for a total of about 1000 convulsions, von Meduna⁶ has reported cases in which the only injuries were a dislocated arm and in two instances a dislocated jaw. Only 4 fatalities have been reported to date [Kennedy].¹ 1 of these patients had aortic regurgitation and 1 a hypernephroma (both clinically diagnosable); the other 2 deaths were due to pulmonary embolism. Kennedy states the fatality rate to be 0.3 per cent.

ducing epileptic attacks in schizophrenic patients a change in the chemical, humoral, hematologic and other aspects of the organism is brought about and a possibility given for a remission. The soundness of the clinical basis for such an antagonism is doubtful, since most clinicians have observed rare epileptic schizophrenics and schizophrenic epileptics.* But it has been shown by many investigators, notably Hoskins and Langfeldt, that there are various biochemical and metabolic anomalies which characterize the schizophrenic patient observations which Friedman,² who introduced the convulsion treatment in America, considers to be indicative of a type of sluggishness in the somatic economy. Friedman postulates "a functional barrier to facile absorption or assimilation of nutritive elements set up in the brain," and considers that therapy should be directed against this barrier in order that normal nutritive mechanisms may be reinstated, "thus providing an unblocked pathway for normal mental functions." With the use of metrazol, which is a medullary stimulant, he postulates that the vital centers are affected and that the supposedly sluggish vegetative nervous system is mobilized to action.

The question of whether convulsions are necessary for optimal results has been raised by Friedman, who points to the frequent occurrence of petit-mal and delirious reactions as equivalents of the usual grand-mal seizures, he is of the opinion that both delirious reactions and convulsive seizures are necessary for the best results.

It appears that the drugs employed to date are not specific, and that their importance consists entirely in their convulsant properties. For this reason the technic adopted by various investigators has been directed toward the establishment of as low a convulsive threshold as possible in order that dosages may be kept minimal. To this end Friedman,² for example, has advocated alkalinization and hydration for the establishment of a low convulsive threshold. He has suggested that the patient be placed on an alkaline diet for about a week preceding treatment and throughout its course, sodium bicarbonate, 2 to 3 tablespoonfuls daily, or its equivalent, is also administered, the litmus reaction of the urine is used as a check. In addition, the fluid intake is kept at a minimum of at least 2000 cc. per day. Camphor is then administered for at least three weeks, being injected intramuscularly in 25 per cent oily solution, twice daily, with an initial dose of 4 gm of amorphous camphor, increased 1 gm per day. Following this period, treatment with metrazol by intravenous injection is begun, the initial dose is usually 5 cc

of 10 per cent solution, increased by 1-cc. amounts to the dosage necessary to produce convulsions.

METRAZOL

Metrazol (pentamethylenetetrazol)* is an analeptic drug which is used fairly extensively in general clinical practice as a vasomotor and respiratory stimulant. It tends to raise the blood pressure in conditions of depressed circulation, and to increase the depth of respiration. It is generally used in 10 per cent aqueous solutions. In doses larger than 3 or 4 cc it becomes a convulsant, especially when administered rapidly. Since it is absorbed very quickly it enjoys an obvious advantage over camphor-in-oil solutions, which are administered intramuscularly and reactions to which may be delayed for as long as several hours.

The nature of the effect of metrazol on the nervous system is not clear. From the standpoint of brain function it appears that the vascular system is of primary importance and that the action of the drug is one of progressive involvement of successively higher centers, namely the carotid sinus, medulla, basal ganglia and cerebrum. The significance of the vascular system is indicated in a report by Esser and Kühn,¹ in a postmortem examination of a twenty-two-year-old laboratory assistant who committed suicide by drinking 100 cc. of 10 per cent metrazol solution they found, in addition to lesions in various organs of the body (notably the liver and heart), that the brain was hyperemic with beginning thrombotic processes, the glia and ganglion cells being apparently unaffected. The patient had died in convulsions within an hour. Esser and Kühn believed that the lesions in the heart and brain were more extensive than the amount of metrazol recovered in these tissues warranted.

TECHNIC

Friedman² has listed several general contraindications for the selection of cases for metrazol injection in which the clinical evidence is not clear. These are: evidence of cardiovascular disease, acute febrile infections, menstruation, abnormalities of laboratory findings, and a history of head trauma with subsequent unconsciousness.

The procedures outlined by Friedman with respect to alkalinization, hydration and camphor administration have not been followed by the present investigator. It was felt that these features of procedure represented elaborations which might well be postponed until the efficacy of the simplest procedure could be established. Hence this report deals with the effectiveness of metrazol adminis-

*A critique of the schizophrenia-epilepsy relation has recently been made by Niro.

*The chemical and pharmacologic properties of metrazol have recently been admirably reviewed by Kennedy.

tration only, no other unusual procedures having been carried out

In the observations to be reported, the course of metrazol treatments was begun with 3 cc of a 10 per cent solution. All injections were intravenous. The dosage was increased by 1-cc amounts only when a convulsion of the grand-mal type had not been induced at the lower dosage. Friedman,² following von Meduna,⁶ has established twenty to thirty seizures as the course of treatment, and both maintain that even after recovery occurs two or three more seizures should be induced, injections were given twice weekly. These suggestions regarding duration of the course and frequency of injections seem to be quite arbitrary.

With 1 exception (Case 7), injections were administered three times per week. There is some evidence (Case 7) that beneficial effects may be derived when the drug is administered daily. It is possible that even more frequent administration may be feasible.

CLINICAL OBSERVATIONS*

The sequence of events in a grand-mal seizure induced by convulsive doses of metrazol is as follows:

1 Immediately following the injection there is a latent period which lasts from four to ten seconds.

2 There then frequently ensues a short interval of gasping or coughing, followed by one usually lasting not more than ten seconds during which the patient makes thrashing movements and flails his arms and legs about, his facial expression closely resembling terror. The face is flushed, the pupils become widely dilated, and the eyes stare wildly. In some patients this phase is so brief that it is scarcely distinguishable from the succeeding one, but in others it may last as long as fifteen seconds.

3 This stage is characterized by increasingly rapid, generalized clonic twitches. The pulse rate becomes rapid and the systolic blood pressure is elevated. Although it was felt clinically that the muscular twitches began in the face, examination of our cinematographic records revealed that they began in all muscles of the body simultaneously. Furthermore, it was observed that the twitches occurred on both sides of the body, also simultaneously. The eyeballs jerk upwards, the lids often close tightly, and the pupils remain dilated and do not react to light. Cyanosis becomes more and more marked, and the face and

tongue may become livid. Spontaneous ejaculation, without erection, occurs in most patients, often early in this phase. The thorax is fixed, and for the duration of this phase and the next the patient is apneic. This stage lasts from five to twenty seconds.

4 At this stage the so-called "tonic" phase supervenes. It is usually the most prolonged phase of the seizure, and lasts from fifteen to forty seconds. Characteristically the picture is one of carpopedal spasm. The jaw is opened, the head is hyperextended, the eyeballs are rolled upward and sometimes outward and the shoulders are adducted. Corneal reflexes are absent. The hands, in the position of tetany, are often held just over the genitalia, or may be extended outward. The legs are extended and partially internally rotated. The great toes are maintained in extension and the small toes in flexion. There is a tendency toward opisthotonos and sometimes orthotonus. The cyanosis during this period is extreme.

5 At this stage the clonic phase again supervenes, lasting for a very short interval, the shortest of all. Then quite suddenly all clonic movements disappear. There is a cessation of movement in all muscles of the body, on both sides simultaneously. The patient takes a deep breath, signaling the end of the period of apnea. The pupils often contract with the onset of breathing, but may redilate or manifest hippus. The breathing becomes stertorous, salivation is very marked. The cyanosis rapidly disappears.

6 The patient now is seen to be in a stuporous state. Occasional spontaneous clonic twitches may be noted. Myotatic irritability may be marked. The deep reflexes are usually absent or sluggish. There remains some cyanosis, particularly of the lips and ears. In only 1 of our patients was vesical incontinence noted, and this occurred only infrequently. Rectal incontinence has not been noted. These observations concerning sphincter control are in disagreement with those noted by other writers, who report vesical and rectal incontinence as quite frequent. This may be due to the fact that previous overhydration had been a feature of their experimental regimen. The stuporous state lasts for a variable period, sometimes as long as ten minutes, after which there appears to be a gradual return to the former state of consciousness, lasting fifteen or twenty minutes. During the early part of this stuporous phase the patient is completely relaxed, he does not answer questions or obey commands. Sleep may supervene. As time goes on, however, he becomes more and more re-

*The nature of the convulsions was studied cinematographically in collaboration with Dr. Joseph M. Looney, director of laboratories, Worcester State Hospital.

sponsive* An invariable feature during this phase is retrograde amnesia. This symptom disappears within an hour of the beginning of the seizure. However, the amnesia for the convulsion itself is persistent. Some patients tell of various peculiar experiences just after the injection, such as "The room rotates around and around"—"I see a hundred people that look like you"—"There's a terrific cracking in my head"—"I see black." These experiences are apparently quite frightening and may account, at least to some extent, for the great fear many patients have of the treatment.

It seems worth while to emphasize the probable significance of this fear. After two or three injections some of the patients begin to complain bitterly of the treatment and offer considerable resistance. They say that they are sure they are in no need of it, that it does them harm of one sort or another, that it makes them feel that they are going to die. In some clinics an attempt is being made to overcome these preinjection states of agitation by narcosis, especially with insulin, a suggestion first made by Klaesi in 1937†.

The foregoing description pertains to the grand mal type of seizure. Following about one fourth to one third of the injections, seizures which appear to be of the nature of petit-mal, or of epileptic equivalents, occur. These take diverse forms. Usually they consist of more or less isolated twitches, which last a few seconds, usually involving the face and arms, or the patient's facial expression may merely become fixed and apprehensive. Sometimes he becomes quite excited and hyperactive, performing numerous bizarre movements, such as racing about the room, scratching his head or body, fighting or climbing about on the bed. Stupor apparently does not ensue. The patient has a persistent amnesia for this form of seizure also.

It is of interest that, unlike patients who have just had a true epileptic attack, our patients never complained of lameness or stiffness of the muscles. The reason for this may be inferred from our records: it seems clear that the muscular activity produced is not violent. Overflexion and over-

extension of the muscles, resulting in strained ligaments, apparently do not occur. An exception to this observation may exist in 1 of our patients (Case 1), who dislocated both shoulders.

CASE REPORTS

For purposes of this report 7 illustrated cases are cited. These patients were selected as fairly representative of schizophrenic patients usually found in state hospitals. They are of various types and have been ill for various periods of time.

Case 1 age 24 The onset of schizophrenia had been quite gradual over about 1 year, and was manifested by a change in personality. The patient had become quite irritable, complained of headaches, seemed discouraged, and said that he was a wreck. He began to talk foolishly. On the ward he was quiet but often moved about restlessly. There were numerous mannerisms of the eyes, mouth and hands. His speech was jerky and scattered, his mood shallow. He admitted having heard voices in the past. There were no frankly paranoid ideas.

Metrazol treatment was begun, but after three injections, the last of which was 5 cc., the patient dislocated his right shoulder during a seizure and treatment was discontinued. It was resumed after 6 weeks, but after two injections, the second of which was 4 cc., he dislocated his left shoulder and it was decided to discontinue treatment indefinitely. During the first course he had two seizures and during the second only one. His clinical condition remained unchanged.

Case 2 age 34 The patient was admitted in 1925, at the age of 22, and has since resided on the disturbed ward. The onset occurred some months previously, when he gave voice to various paranoid ideas and was obviously responding to auditory hallucinations. On admission he was restless and complained of various ideas of persecution. The course since admission was that of progressive deterioration, the patient eventually becoming almost entirely mute and presenting a picture of speech and general motor stereotypy. He waved his arms about and danced around the ward in a peculiar manner, making buzzing sounds, sometimes for hours at a time. Wet pack treatment and chemical sedation were frequently necessary.

Metrazol injections were begun and given in doses up to 7 cc. until twenty convulsions had been induced. The patient had two convulsions in doses up to 6 cc., but the remaining convulsions were induced with 7 cc. The clinical condition remained essentially unchanged except for a frank diminution of the stereotyped mannerisms and hyperactivity, which largely disappeared.

Case 3 age 18 Three years before admission the patient had become absentminded, uninterested and seclusive. He talked in a peculiar manner of dying, of mental telepathy and of general muscular weakness. On admission he admitted that he felt peculiar and heard voices. He was quite apathetic. He had been given a course of insulin treatment by Dr. Cameron with no striking change in his clinical condition.

Metrazol treatment was carried out for a course of twenty convulsions. The patient received 25 injections up to a maximum of 10 cc., six fits occurred at 7 cc. and six at 10 cc. No essential change in the clinical condition was observed.

Case 4 age 26 The onset of schizophrenia apparently

*The data on the nature of the return to the former state of consciousness will be reported separately. They offer some illumination of the problem of postconvulsive confusion.

†For Meduna* has observed that various blood and urinary changes occur. The former consisted in an increase of neutrophils and an increase of lymphocytes; the blood picture changes were greater in patients who underwent a remission. The acidity of the urine was increased (about 25 per cent) as were the ammonia (14 per cent) and the phosphates (10 per cent); the chlorides were reduced (25 per cent). These findings support his opinion that the seizures are epileptic. Sorger and Hofmann† reported that during the seizure and immediately after the eosinophils, monocytes and polymorphonuclear leukocytes decreased and the lymphocytes increased; after two or three hours the eosinophils disappeared and there was a decrease of monocytes and lymphocytes and an increase of polymorphonuclear leukocytes. The blood picture again became normal about six hours after the seizure. These men also report a rise of the blood sugar level immediately after the seizure, the maximum being reached after about thirty minutes, followed by a rapid fall to normal.

†The concomitant utilization of insulin induction also seems to lower the convulsive threshold; a smaller amount of metrazol therefore being sufficient. (See p. 2 Geer, and Strauss.)

occurred 3 years before admission, with persecutory delusions and bizarre visual and auditory hallucinations. A partial remission occurred for a few months, but the patient again became ill, with essentially the same clinical picture. On admission he was preoccupied, unco-operative, and disinclined to talk. He had numerous persecutory delusions and visual, auditory, and olfactory hallucinations. He was given a full course of insulin treatment by Dr. Cameron and manifested a partial remission which lasted several months, but again relapsed to his former clinical state.

Metrazol treatment was carried on until twenty convulsions had been induced. Twenty-three dosages were necessary, gradually increasing to 7 cc. per dose. The clinical condition improved markedly after the eighth seizure. The patient said that for the first time in years he felt quite normal. His speech became active and lively, but the voices, in the form of whispers, persisted. Some of the persecutory delusions also remained, but did not disturb the patient. This marked improvement persisted for about 3 weeks, during which treatment was continued. The patient then underwent a partial relapse. Although a fit had been originally induced with 3 cc., none was subsequently induced until 7 cc. was reached and the patient remained at that dosage. At a recent examination he complained that his memory was poor and thoughts 'stuck' in his mind. On the other hand he felt better than he had previously, except for the period of marked clinical improvement.

Case 5, age 24 This patient had for years been concerned with his state of health and had exaggerated his somatic complaints. About 3 years before admission he began to talk unceasingly of his health. He lost interest in everything else. He gave voice to many bizarre ideas, such as that the bones of his head were soggy and decayed, that his forehead and nose had sunk in, that his palate had fallen, and that his head expanded and contracted rhythmically, and that the bones in his chest were soft. On admission to the Worcester State Hospital he was quite emaciated, and referred constantly to his somatic complaints.

Metrazol treatment was carried out until a course of twenty convulsions had been completed. Twenty-five doses were necessary, at increasing levels to a maximum of 14 cc. When the course was about half complete the patient suddenly announced that he felt much better, but he again relapsed. From time to time over the ensuing weeks he denied all his somatic complaints for as long as a day or two at a time, but after the seventeenth convulsion his complaints entirely disappeared. Treatment was stopped after 20 seizures because the patient's improvement seemed to be quite permanent. He gained 8 lb. and seemed quite interested in returning home and finding a job. He was discharged in a complete remission.

Case 6, age 29 The patient had been a vagrant for many years and was admitted because he was actively hallucinated, talked to himself and seemed silly. On the ward he was markedly overactive, and dashed for the door in an excited manner. His speech was quite disjointed. It was necessary to keep him in seclusion for a year after admission because of his excitement and untidiness.

Metrazol treatment was carried on for eleven injections, during which the patient had six convulsions. A maximum dosage of 9 cc. was reached. The patient improved markedly, became quiet and co-operative and dressed himself, and it was possible to keep him on the ward, although he still dashes toward open doors, he is entirely manageable. Treatment was discontinued because

the patient's improvement was so marked that it was felt unwise to prolong it—a procedure which may be unjustified.

Case 7, age 28 Five months before admission the patient became seclusive and ate poorly. He expressed paranoid ideas and was actively hallucinated. On admission he was unco-operative and resistive, and soon thereafter became extremely excited. He was antagonistic and threatening and had to be kept in seclusion. Constant pack treatment was necessary. He refused to dress, was untidy and had to be tube fed. He became quite emaciated. The picture seemed to be one of an acute excitement with a very grave prognosis.

Four daily injections of metrazol were administered, and since he failed to react after one injection at 3 cc., the dosage was raised to 4 cc. to induce two of the three seizures. Immediately after the second seizure he asked for food for the first time in several months. After the third he again asked for food. The same day he became quiet and co-operative and thereafter dressed and fed himself. It was no longer necessary to keep him in seclusion. In the ensuing three weeks of hospitalization the patient appeared quite normal. Although on one occasion he complained of hearing voices at night, these hallucinations disappeared and the patient on discharge was entirely symptom free. He gained 25 lb. He referred to his previous illness as a nightmare, but beyond this said he could not remember or understand what had occurred.

The patients reported here, all male schizophrenics, had been ill for periods of from five months to about fifteen years. Following treatment, 3 patients remained unchanged, 3 improved—2 quite markedly—and 2 manifested complete remissions. The most dramatic recovery occurred in an excited patient who had been ill about six months, but recovery also occurred in a patient who had been ill for many years.

From this limited number of cases it is impossible to formulate any generalizations as to the prognosis under this form of therapy in terms of the duration of the disease. However, one may say roughly that the prognosis appears better in patients in whom the disease process is recent. And it would appear that the improvement rate, even in this generally unfavorable group of patients, is fairly high.

SUMMARY AND CONCLUSIONS

A brief review of the rationale and efficacy of the convulsant treatment of schizophrenia has been presented, and 7 cases of representative schizophrenics treated by this method are recorded. The simplest manner of administration of this therapeutic procedure, namely intravenous injection of metrazol over a period of time, has been described. The nature of the resulting grand-mal convulsion, from clinical and cinematographic observations, is described. The results of other investigators who have reported more extensive series are presented, from their data it seems

quite clear that the prognosis is better the earlier in the course of the disease process the treatment is begun

The question arises in this connection, as in all therapeutic procedures in schizophrenia, of the true worth of metrazol injection. Disappointment, often after long optimism, has been the rule. Probably final judgment must be reserved until a sufficiently large body of data has been placed on record and the permanence of improvement or complete remission has been established after a five to ten-year period. Strict comparisons with the spontaneous remission rate are essential. It seems from these preliminary data that the convulsant treatment of schizophrenia arouses considerable hope, and is therefore worthy of more extensive investigation. The theoretic basis for this form of treatment is still uncertain, and presents numerous problems. The psychologic factors involved, especially the fear of treatment that is induced in many patients, merit the most careful evaluation.

SPONTANEOUS THYROID STORM ASSOCIATED WITH DIABETIC ACIDOSIS AND PARALYTIC ILEUS

Report of a Case With Autopsy Findings

EMMANUEL DEUTSCH, M.D.*

BOSTON

IN A search of the available literature I have been unable to find another case presenting spontaneous thyroid storm associated with diabetic acidosis and paralytic ileus. Hypoglycemic convulsions followed by pulmonary edema terminated the course in the patient reported herewith.

CASE REPORT

A 22-year-old American, white, married newspaper bundler (B. C. H. No. 875116) entered the hospital October 3, 1937, because of diarrhea and vomiting of 1 week's duration. His health prior to this time had been good. Except for a moderate degree of nervousness during the previous month, there were no significant facts in his social, family or past history.

Starting one week before entry the patient began to have attacks of diarrhea, with five to seven yellowish-brown watery movements daily. With them mild, cramp-like abdominal pain occurred. The stools were never clay-colored, contained no pus or blood and were not associated with tenesmus. Vomiting developed 3 days prior to entry and persisted, being most marked 5 to 30 minutes after meals. The vomitus contained, for the most part, undigested food, and the attacks were preceded by mild nausea.

Anorexia was marked and a weight loss of 15 lb was noted during this week. No icterus was apparent. In addition to these gastrointestinal symptoms, palpitation became annoying. The patient was nervous, restless and unable to sleep. He complained of sweating and of feeling warm, yet had no chills or chilliness. Nocturia, increasing to seven times, developed. Weakness prevented activity and forced continued rest in bed. For several days before entry the vision seemed blurred. Two days prior to admission a rash appeared on the face and chest.

On physical examination the patient was a small emaciated youth, rational but severely prostrated. He weighed approximately 130 lb. The hair distribution and texture, and the skull, ears, nose and throat were all normal. Both eyes were symmetrical and prominent to a moderate degree, and showed lid lag and poor convergence. A slight puffiness of the lids was noted. The pupils reacted to light and accommodation, and ophthalmic examination revealed a clear media and normal fundi. The tongue was dry and coated and exhibited no tremor. There was a marked acetone odor of the breath. The neck was not stiff, and the carotids pulsated strikingly. A generalized, pea-sized, non-tender adenopathy was accentuated by the degree of emaciation. The thyroid gland was not palpable, nor did it exhibit any nodules, bruits or thrills. The trachea was in the midline and there was no trace of tracheal tug. The lungs were resonant, the breath sounds normal, rales absent, and the respirations 32.

The heart was not enlarged, and on palpation revealed

*From the First Medical (Tufts Teaching) Service, Boston City Hospital.
Instructor in clinical medicine, Tufts Dental School; resident admitting physician, Boston City Hospital.

marked precordial activity. The aortic second sound was greater than that at the pulmonic area. No murmurs could be detected, and the heart sounds were loud and clear. The rate was 160, and the rhythm regular. Very loud pistol shot sounds were heard over all arteries, and the patient had a Corrigan pulse. The arteries were normal in size and consistence. A blood pressure of 360+/0 in both arms was recorded on several occasions. Unfortunately the spring type of sphygmomanometer was not checked with the mercury type.

The skin was warm but not moist. There was a sparse, discrete, maculopapular rash on the face and chest with lesions measuring 1 to 2 mm in diameter. The abdomen was tense but not distended or tender, and revealed no masses. The liver and spleen were not felt on repeated examinations. Tremor of the hands was absent, and the reflexes were active. The temperature on admission was 101°F.

On admission repeated urine examination showed a specific gravity of 1.025, no albumin, complete reduction for sugar and a 4+ acetone test, only occasional white and red cells appeared in the sediment. The fasting blood sugar was 217 mg, the nonprotein nitrogen 57 mg, and the carbon-dioxide combining power 22 vol per cent. Two blood cultures and one blood Hinton test were negative. The white-blood-cell count ranged between 15,000 and 19,000 with 98 per cent polymorphonuclears and 2 per cent lymphocytes. The blood smear was otherwise normal. The hemoglobin was 92 per cent and cholesterol 75 mg per cent. Two electrocardiograms showed sino-auricular tachycardia.

The patient was treated intravenously with saline solution containing 10 per cent glucose and 400 units of insulin during the first day. By the morning of the following day he was quieter and free of acetone, but still showing a red, sugar reduction in the urine. The blood pressure was now 170/85. The pulse rate ranged between 140 and 180, the respirations were 30 to 35, and the temperature was 100 to 102°F. Vomiting and diarrhea were not present.

On October 5 the patient began to hiccough and complained of mid-abdominal discomfort. Two hours later he had fecal vomiting for the first time, this persisted for half an hour, the patient lapsing into coma. The abdomen became rigid and level, flatness on percussion could be elicited in the flanks as well as in the midabdomen. The blood pressure was at a shock level, with the pulse at 180 and weak, and a cold, clammy skin. Gastric lavage was started and yielded 2300 cc. of fecal, fluid material, the clinical response was dramatic. The blood pressure rose to 110/40 as consciousness returned. Later that day it was 140/80. A Wangensteen apparatus was then set up to syphon off excessive gastrointestinal contents, it had to be left in place, because as rapidly as intravenous fluids were given, an almost proportional accumulation of fecal fluid appeared.

On October 4 and 5 the patient was given 10 min of Lugol's solution every four hours, and intravenous fluids were maintained almost constantly. On October 6, 50 min of this solution were added to each liter of normal saline and glucose given intravenously. The patient continued to become progressively irrational and lost weight rapidly.

On October 6 the nonprotein nitrogen was 87 mg, blood sugar 240 mg and chlorides 616 mg per cent. Acetone reappeared in the urine, glycosuria having persisted throughout the hospital stay. The skin was only mildly warm, and not flushed or dry. At no time did the temperature rise over 102°F, probably because of the intermittent acidosis present.

During October 7 and 8 the patient was drowsy, yet could be roused easily. On October 9 the blood sugar was 30 mg per cent, and concentrated glucose was given intravenously. Before much of this had been given, tonic and clonic convulsions occurred, followed by rapidly developing pulmonary edema and death.

Autopsy Report The essential findings 4½ hours post mortem were as follows. The thyroid was moderately enlarged and weighed 40 gm. Its external surface was brown and smooth. The cut surface was dark brown and granular, the granules being 0.2 to 0.3 cm in diameter and of a lighter color than the surrounding tissue. The cut surface of the lungs was red and crepitant, and small amounts of pink, frothy fluid could be expressed from all areas. The stomach contained several hundred cubic centimeters of black, foul smelling fluid. The gastric mucosa appeared dark red, and irregular, shallow ulcerations, 0.2 to 0.3 cm in diameter, were scattered throughout. The first two portions of the duodenum were distended, and its mucosa was gray. Scattered throughout the terminal portions of the ileum and ascending colon were areas 5 to 10 cm in width in which the mucosa was red yet contained no ulcerations. The liver weighed 1750 gm and showed no gross abnormality. The entire aorta appeared narrower than usual, and the arch of the thoracic aorta had a circumference of 4.5 cm. Scattered through the abdominal and thoracic aortas were small, yellow, atheromatous plaques.

The anatomical diagnoses were hypertrophy and hyperplasia of the thyroid gland, acute gastritis, early atherosclerosis of the thoracic and abdominal aortas.

Cultures of the heart's blood showed no growth.

Courtesy of Dr. G. Kenneth Mallory

Figure 1 A photomicrograph of medium power showing marked hyperplasia of thyroid gland

- A—an area of acini without colloid,
- B—papillary projections into acinus,
- C—columnar epithelium

Microscopic examination of the thyroid showed three distinct areas of marked hyperplasia. There were many acini without colloid, another area revealed large acini with marked papillary projections of their walls. In still another area the acini were lined with epithelium of a columnar type. Around a small, necrotic, cardiac muscle bundle there was a small focal accumulation of polymorphonuclear leukocytes. In the walls of the bronchi and immediately adjacent alveoli were collections of polymorphonuclear leukocytes and a few lymphocytes. The

spleen contained moderate amounts of phagocytosed hemoidin. There was extensive ulceration of the esophageal epithelium. The submucosa was diffusely infiltrated by large numbers of polymorphonuclear leukocytes and contained small deposits of fibrin and thrombosed blood vessels. There were large areas of extravasated red blood cells in muscular layers and diffuse infiltration of these layers by polymorphonuclear leukocytes. There was an ulceration of the gastric mucosa, and in this area the surface was composed of polymorphonuclear leukocytes, red blood cells, fibrin and necrotic tissue. There were large areas of interstitial hemorrhage in the submucosa, and scattered throughout were many polymorphonuclear leukocytes. Occasional polymorphonuclear leukocytes and histiocytes were noted in the muscular layers, and there was a small deposit of fibrin on the serosal surface. The interstitial pancreatic tissue showed small numbers of polymorphonuclear leukocytes. These cells were occasionally present in small masses around the islands. The liver appeared to be negative. Since no vacuoles were seen, glycogen and fat stains were not done. In the adrenals there were foci of necrotic cortical cells with early infiltration by polymorphonuclear leukocytes. There was marked hyperactivity of the bone marrow.

The microscopic diagnoses were: marked hyperplasia of the thyroid gland, acute bronchitis, acute hemorrhagic gastritis, focal necrosis of the corticoadrenal cells.

Unfortunately permission to examine the head was refused, so that the pituitary gland could not be examined.

DISCUSSION

Hyperthyroidism and Diabetes Mellitus It has long been known that disturbances in carbohydrate metabolism occur in hyperthyroidism.^{1,2,3} Opinions differ widely as to the character, frequency and conditions of these anomalies.^{4,5,6,7} Some authors find glycosuria present in only a small percentage of patients with exophthalmic goiter, while others have found it in over 90 per cent of their cases. Consequently Joslin, Root, White and Marble⁸ have suggested an arbitrary standard for diagnosis of diabetes in hyperthyroidism, namely a blood sugar of 0.15 mg per cent fasting, or of 0.2 mg per cent or more after meals, in addition to glycosuria.

In more than half the uncomplicated cases of exophthalmic goiter studied by Andersen⁹ the fasting blood-sugar level was a little higher than is considered normal. The alimentary blood-sugar curve was increased in height and duration. The latter was most marked in the more severe cases, yet there were several exceptions.

The mechanism of the sugar-excretion threshold, according to Cushny¹⁰ and later Ni and Rehberg¹¹ depends upon the filtration of glucose through the glomeruli and its reabsorption in the tubules. This reabsorption is dependent upon the blood-sugar concentration, and when this reaches a certain level, known as the excretion threshold, the glucose contained in the glomerular filtrate can no longer be absorbed completely in the tubules and glycosuria results. Which factors determine this reabsorption of glucose has not yet been settled, but it is the

predominant view that the influence is of a hormonal nature, a hormone from the pituitary perhaps being responsible.

Joslin and Lahey¹² have indicated the seriousness of this clinical combination. The average duration of life for their group of cases was 3.4 years.

Hyperthyroidism and Hypoglycemia Blood-sugar studies on postoperative thyrotoxic patients observed by Holman¹³ showed a rather sudden onset of hypoglycemia twenty-four to thirty-six hours after operation in 2 patients, who responded dramatically to glucose therapy. Here manipulation of the gland during operation resulted in flooding the general circulation with a large amount of thyroid secretion. Consequently a tremendous increase in metabolic processes occurred, causing a utilization of available carbohydrates, especially the glycogen reserve of the liver and muscle tissues. Now, if there is sufficient active thyroid secretion in the circulation—which may be the case either in the spontaneous or the postoperative thyroid storm—there will come a time when all available carbohydrate supply of the body is depleted and hypoglycemia is precipitated. That this condition occurred as a terminal feature in the case presented is shown by the sugar determination of 30 mg per cent after a fairly persistent hyperglycemia and glycosuria. The remarkable loss of body weight while on the ward appears to have paralleled the tremendous amount of sugar excreted in the urine.

Pulmonary edema was noted clinically as a terminal feature, a finding which Maddock, Pedersen and Coller¹⁴ have commented upon as a frequent terminal event associated with increased amounts of adrenine in the blood stream in cases of thyroid crisis, while neglecting the role of hypoglycemia. These authors report 3 typical cases of severe postoperative thyroid crisis in which pulmonary edema developed, 1 patient who recovered showed a negative chemical test for adrenine, whereas it had previously been positive. These authors believe that this respiratory complication has been overlooked in many cases in the past, the excessive mucus and the cyanosis being attributed to bronchopneumonia and tracheitis.

If blood-sugar studies are done more frequently, more cases of thyroid storm may show, as did ours a sudden onset of hypoglycemia, which probably stimulates the adrenal medulla to secrete large amounts of adrenine into the blood stream and results in the terminal pulmonary edema. Another possibility is acute left ventricular failure, due to the hypertension and causing pulmonary edema.

Acute Abdominal Symptomatology in Hyperthyroidism Kraus¹⁵ and Desbours¹⁶ describe cases of acute abdominal pain occurring during the

course of thyrotoxicosis. There are very few references to this factor in the American literature. Robertson, Wohl and Robertson¹⁷ describe 3 cases of moderate hyperthyroidism with abdominal symptoms simulating a surgical abdomen. Acute attacks of vomiting and abdominal pain may be due solely to overactivity of the thyroid gland. With the administration of compound solution of iodine the symptoms of thyrotoxicosis and abdominal pain are entirely relieved, but when iodine is omitted the thyrotoxic symptoms reappear.

Differentiation is at times impossible, especially if we bear in mind the rather high incidence of duodenal and gastric ulcers in patients with thyrotoxicosis.¹⁸ The acute abdominal symptoms of diabetes mellitus must also be considered in the differential diagnosis. It is possible that in our case there was a summation of the effect of the diabetic and thyrogenic factors upon the gastrointestinal tract, resulting in paralytic or adynamic ileus, a finding not encountered in the literature of hyperthyroidism or of diabetes mellitus. It was this almost persistent gastrointestinal catastrophe which made it impossible to maintain an adequate caloric intake.

Thyroid Storm or the Comatose Form of Graves's Disease. The hyperthyroid aspect of this case conforms in many respects to Zondek's¹⁹ classical description of the comatose type of Graves's disease. Some mild infection such as tonsillitis or bronchitis may cause the tremor and restlessness characteristic of Graves's disease to give place suddenly to intense asthenia, or there may be no such preliminary. Toxic phenomena such as wasting, sweating or tachycardia may suddenly occur, even though the metabolic rate is not much increased, also, exophthalmos and goiter may be slight or absent.

After a variable period of excitement consciousness grows dimmer, a peculiar rigidity develops in which facial expression is lost, and the countenance assumes a blank look. Later the patient may lose consciousness almost completely. Except for lack of rigidity of the limbs, the condition resembles catalepsy. The mouth and other mucous membranes are extremely dry. A serious symptom is difficulty in swallowing, which may lead one to suspect bulbar paralysis.

At the Massachusetts General Hospital, Means²⁰ has reported that from 1924 to 1935 there have been 14 patients with postoperative storm, 10 (71 per cent) of whom died. Consequently thyroid storm still constitutes an important cause of death.

The Chronic Form of the Acute Syndrome. Cases of Addison's disease following thyrotoxicosis have been reported by Etienne, Etienne and Richards,²⁴ Chauffaud and Giro,²⁵ and Brenner²⁵

That the adrenal cortex inhibits thyroid activity has been shown by Marine and Baumann.²⁶ They found that incomplete destruction of the adrenal cortex in rabbits with intact thyroids—but not in those with thyroids removed—caused a rise in body temperature, and they suggested that adrenal insufficiency might be the cause.

Recent evidence²⁷⁻²⁸ suggests that the adrenalectomized animal develops hypoglycemia because it cannot form liver glycogen from endogenous sources, this may be the cause of the hypoglycemia so often noticed in this disease, and may explain the occurrence of the convulsions and coma—in the absence of hemoconcentration or changes in blood chemistry—that are characteristic of Addisonian crisis.

Anderson and Lyall²³ described a case of thyrotoxicosis in a thirty-year-old single woman who developed Addison's disease seven years after x-ray therapy. Coma and muscular spasm which occurred as terminal symptoms seemed directly related to extreme hypoglycemia rather than to Addisonian crisis, since plasma electrolytes and the blood volume were within normal limits.

SUMMARY

A case of spontaneous thyroid storm, diabetic acidosis and paralytic ileus which terminated in hypoglycemic convulsions and pulmonary edema is reported, with autopsy findings.

An explanation offered for the mechanism of this death is that spontaneous liberation of an enormous amount of active thyroid secretion into the general circulation precipitated the hypoglycemic convulsions, which were followed by the rapid development of pulmonary edema and death.

It is suggested that a summation of the extreme effect of both the thyrogenic and the diabetic factors upon the gastrointestinal tract resulted in paralytic ileus.

The importance has been indicated of following the condition with frequent blood-sugar determinations to discover the critical period when exhaustion of the body's glycogen supply occurs, and the value of glucose therapy has been noted.

I am indebted to Dr. Joseph E. Hallissey for permission to publish this case.

THE INCIDENCE OF TUBERCULOUS INFECTION IN SURGICALLY REMOVED TONSILS

LOUIS ALPERT, M.D.*

MIDDLEBORO MASSACHUSETTS

MANY workers have reported from time to time on the frequency of tuberculous infection in extirpated tonsils. Most of this work has been done in the clinics of general hospitals. Weller¹ in 1921 reported a study of surgical material received routinely in the laboratory from 1906 to 1919, the incidence of histopathology of tuberculosis in 8607 specimens was found to be 2.35 per cent. Mullin² analyzed 400 cases and found an incidence of 4.3 per cent, but in 60 per cent of these cases there was evidence of tuberculosis elsewhere. Wilkinson³ reported that whereas the incidence of tuberculous infection in 600 tonsils removed in 1900 was 1.3 per cent, this figure dropped to 0.5 per cent for 10,000 tonsils removed from 1923 to 1927. Magee⁴ carried on this kind of study to determine whether the decreased incidence of most forms of tuberculosis would be reflected in the tonsillar tissue examined. She showed the incidence in 6280 tonsillectomies performed from 1933 to 1935 to be 0.4 per cent. This is a definite decrease as compared to 2.35 per cent reported¹ from the same clinic in 1920. I have seen no reports in the literature on the frequency of tuberculous infection encountered in tonsils removed in institutions for tuberculous patients.

In this communication I report the results of 202 tonsillectomies performed on patients, mostly children, at the Lakeville and North Reading state sanatoriums between 1933 and 1937. Of these patients, 172 were operated on at Lakeville, where all forms of extrapulmonary tuberculosis are

treated, and 30 at North Reading, where the childhood type of pulmonary tuberculosis is treated. The indications for removal of the tonsils were chiefly their injected and cryptic appearance, a history of frequent sore throat, and the presence of suppurative cervical lymph nodes. We have found that the cervical-lymph-node cases almost invariably benefit from tonsillectomy, and urge this procedure in such cases as a matter of routine.

Of the 202 specimens examined histopathologically, 21, or 10 per cent, showed tuberculous infection. Six of these were removed from the 30 patients at North Reading, and 15 from the 172 patients at Lakeville. The infection found in the removed tonsils may be considered as latent, for in no case was there a preoperative diagnosis of tuberculosis of the tonsils. The tuberculous lesions for which the patients were admitted to the sanatoriums are listed in Table 1, together with the appearance of the tonsils on admission and other data of interest. The throats did not differ in appearance to any great extent from those of patients in whom tuberculous infection was not found. In fact, they resembled those seen in any group of people of a corresponding age with tonsils remaining. Of interest, however, is the fact that 10 of the 21 patients had palpable cervical lymph nodes.

Many workers⁵ support the view that the tonsil or the pharyngeal mucous membrane is the portal of entry for the tubercle bacilli. With the mucous membrane intact, the healthy tissue can resist the bacilli, but when its continuity is broken, either

Lakeville State Sanatorium, Middleboro, Massachusetts
Senior physician, Lakeville State Sanatorium

by a tear or by disease, the organisms may easily enter the deeper structures. From there they may travel to the cervical lymph nodes or to any other part of the body, or they may lie dormant, thus becoming a possible source of further auto-infection.

It is not my purpose to prove that these tonsils were or were not the primary foci of the tuberculous lesion that brought the patient to the sana-

tonsils removed, whether in a sanatorium, a general hospital or at home, also appears desirable.

SUMMARY AND CONCLUSIONS

Of 202 tonsils removed from patients at the Lakeville and North Reading state sanatoriums, 21, or 10.4 per cent, showed tuberculous infection.

These tuberculous tonsils, in general, by appearance and behavior could not be distinguished from

Table 1 *Data on 21 Cases in Which Tuberculous Infection Was Found to Be Present in Surgically Removed Tonsils.*

CASE	AGE	TUBERCULOUS LESION FOR WHICH ADMITTED	PREVIOUS SORE THROAT	CONDITION OF CERVICAL LYMPH NODES ON ADMISSION	CONDITION OF TONSILS ON ADMISSION
1	37				
2	2	Peritonitis	Infrequent	None palpable	Not remarkable
3	6	Spine	None	1 on left side	Not remarkable

18	3	Childhood	None	Few palpable	Medium sized
19	12	Childhood	Occasional	None palpable	Enlarged cryptic
20	10	Childhood	None	None palpable	Medium cryptic
21	7	Childhood	None	None palpable	Enlarged cryptic
22	11	Childhood	None	History of drainage	Medium enlarged cryptic

torium. My desire is to emphasize the high percentage of tuberculous infection found in the tonsils of these patients, who were suffering from one form or another of the disease.

If we assume that the tonsils are the first structures to harbor tubercle bacilli, then their early removal, in such cases, may prevent the further spread of the infection to more vulnerable parts of the body. On the other hand, if we discount the above view, we must bear in mind that tuberculous infection in the tonsils is always a potential source of subsequent auto-infection with the development of other and more serious lesions. The necessity for the removal of all abnormal or suspicious tonsils in cases with tuberculosis thus becomes apparent. The routine examination of all

chronically infected tonsils ordinarily encountered.

The removal of all diseased tonsils in children and adults suffering from tuberculosis is recommended.

All tonsils thus removed should be subjected to a careful histopathological examination.

CASE 24241

PRESENTATION OF CASE

A forty-two-year-old, native-born, white housewife entered the hospital with the complaint of fatigue and weakness of eight months' duration.

She was entirely symptom free until eight months before entry when, over a period of two months, she had four attacks of nausea, vomiting and "gas" accompanied by epigastric and right upper quadrant pain radiating to the midscapular region. The attacks lasted several hours and were severe enough to require hypodermic injections for relief. She was advised to have an operation but refused, and because of apprehension ate very little for the next month, with consequent loss of weight. Her physician, however, finally made her take a well-rounded, low-fat diet, but in spite of this she continued to lose weight, losing a total of 23 lb before she entered this hospital. She had no attacks of pain and nausea during the six months before entry, but she had frequent attacks of epigastric fullness and gas on the stomach. She also worried a great deal and was very easily fatigued. She had no jaundice, hematemesis, melena, diarrhea, clay-colored stools, change in bowel habits or change in the color of her urine.

Nine years before entry she had a left salpingo-oophorectomy for acute lower abdominal cramps and fever. Twenty months before entry a mole was removed from her left forearm. At the time of the operation the surgeon noticed flecks of pigment deep in the subcutaneous tissue beneath the lesion and did as wide an excision as possible. He advised an axillary dissection which was refused. The pathological report was melanotic sarcoma. Her past history was otherwise essentially negative, and her family history was noncontributory.

Physical examination revealed a thin, undernourished woman in no acute distress but quite apprehensive. There was tenderness to deep palpation in the right upper quadrant, and liver dullness extended two fingerbreadths below the costal margin although the edge could not be palpated. The heart and lungs were negative, and the blood pressure was 106 systolic, 70 diastolic.

The temperature was 98.6°F., the pulse 90. The respirations were 20.

The urine had a specific gravity of 1.008 and

contained a slight trace of albumin. The blood showed a red-cell count of 3,880,000 with 70 per cent hemoglobin and a white-cell count of 20,500 with 74 per cent polymorphonuclears.

On the third day a laparotomy was performed.

DIFFERENTIAL DIAGNOSIS

DR HORATIO ROGERS. The attack eight months before entry which opens this history is suggestive of acute cholecystitis. As the story goes on, however, the patient has no more pain. Her loss of weight is not accounted for by her dietary habits because it is stated that in spite of a well-balanced diet she continued to lose weight. Her general complaint is fatigue, weakness and loss of weight, and to that we can add anemia and hypotension. Those things we are sure of.

The common causes of such symptoms and findings will have to be considered, but before doing so we might scrutinize this episode twenty months before entry, when she had an excision of what was thought to be a pigmented mole but which turned out to be a melanotic sarcoma. The surgeon was unable to do as extensive an operation as he would have liked to do so that we are justified in supposing that she may not have been cured. Is there anything in this picture that is incompatible with that supposition? Metastases would account for her enlarged liver, which in turn might cause her high white count. Progressing sarcoma would account for fatigue, weakness, anemia and loss of weight. Her hypotension could be accounted for on the basis of metastases in the suprarenals, although it is hardly necessary to account for it specifically in a woman who is apparently so sick. We know that melanotic sarcoma is highly malignant that it metastasizes very widely, and that it has two general methods of metastasizing, visceral and cutaneous. She obviously has no cutaneous metastases, but that does not mean she could not have visceral metastases and, if she has, they will undoubtedly be in the liver because of being blood borne rather than lymph borne. No melanin is reported in the urine, which is surprising if her viscera are full of melanotic sarcoma. If I am right it means that melanin was not looked for.

I believe that this is the best explanation of the whole picture, but in order not to leave anything out, I think we should consider some of the other causes of weakness and fatigue, loss of weight and so on.

Could she have chronic blood loss from a bleeding ulcer, perhaps accounting for her upper abdominal episode? No blood was found in the stools or at least there is no record of it, also I am told that with chronic blood loss her hemoglobin would be lower in proportion to her red count. She has not much anemia.

Could it be chronic sepsis from the gall bladder? She was too sick for that. Her disease has progressed far when her general health is taken into consideration, yet there are no further symptoms referable to the gall bladder.

There is no indication of liver abscess. She has had no chills and her temperature is not high. Tuberculosis and syphilis I cannot rule out, but there is nothing in particular to make us think of them here.

As regards disease of the adrenals, Addison's disease, there is no pigmentation of the skin, and we can account for her hypotension on other grounds.

If it were cancer other than melanotic sarcoma it would have to be cancer of the stomach or liver or gall bladder, either metastatic or primary. There is no reason why it could not be, but we already have an etiology for metastatic malignant disease staring us in the face which I am afraid not to use.

My diagnosis, therefore, is extensive visceral metastases from a non-cured melanotic sarcoma.

PREOPERATIVE DIAGNOSES

Chronic cholecystitis with cholelithiasis
New growth?

DR ROGERS'S DIAGNOSIS

Visceral metastases from melanotic sarcoma

ANATOMICAL DIAGNOSES

Metastasizing melanotic sarcoma, involving gall bladder, skin, intestines, spleen and both adrenals

Melanosis of kidneys
Bronchopneumonia

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY When this patient came into the hospital the full details in regard to that mole were not known. The symptoms in the right upper quadrant were suggestive enough so that it was felt worth while to explore with the question of cholecystitis in mind. That was done and a most extraordinary gall bladder found. It was covered with black spots on its surface and contained internal, large, dangling polypoid masses, which were also black, and which one might easily imagine might have extended down into the neck of the gall bladder and produced obstruction, just as a stone might. The gall bladder was removed but any further treatment seemed pointless and she was discharged to another hospital where she remained for one or two months until death. During the terminal period she developed intractable diarrhea and eventually, many black spots in the

skin. The autopsy was performed there. This is the gall bladder and even those of you who are sitting in the back of the room can see the multiple black nodules. One of the most striking features of the autopsy was the kidneys. They were almost jet-black in color and on section virtually every glomerulus contained masses of melanin. The melanin in the glomeruli seems mostly to be contained in foci of metastatic tumor, but there is also a great deal of the melanin which has been absorbed by the tubular cells. I think there is no question but that she had marked melanuria during the later stages of life that could have been found easily if it had been looked for. So far as I know, it was not. There was complete destruction of one adrenal by the tumor and metastases in the other adrenal which may or may not have had something to do with the symptoms. The entire gut was lined with hundreds of tumor nodules looking like polyposis but all consisting of melanoma. There were metastases in the spleen, which is not uncommon in sarcoma, whereas it very seldom occurs in carcinoma. The most surprising feature of the autopsy was that even with the most careful search not the minutest nodule of tumor could be found in the liver.

CASE 24242

PRESENTATION OF CASE

A fifty-two-year-old, white, American physician entered the hospital with the complaint of abdominal pain, diarrhea, fever and malaise of four months' duration.

For eight or ten years he had four or five semi-solid bowel movements daily, without pus or mucus in the stools, and studies had shown a "spastic colon." Eight months before entry he had an attack of acute pain centered around the umbilicus which was relieved by gr $\frac{1}{4}$ of morphine. The attack cleared up in a day. Four months before entry he had an attack of apparent enteritis, characterized by chills, fever, diarrhea, distention of the abdomen and generalized abdominal pain. There was an epidemic of enteritis at that time in the community where he lived. The acute attack lasted for about a week, but he never fully recovered. Three months before entry his symptoms became worse, and he had acute umbilical pain and "catching" pain in the right costal margin which required gr $\frac{1}{2}$ of morphine for relief. Two days later a laparotomy was performed for removal of a ruptured appendix. The abdomen was full of serum, and the appendix was thought to be ruptured at its base. The ileum was said to be normal. He had a rather stormy con-

valescence and drained material from the wound for a month. One of two cultures of this was positive for streptococci. On the fifth postoperative day he passed five, large, soft stools which did not contain blood. He resumed ambulatory activity one month after the operation but developed mild fever and malaise which subsided on bed rest. Subsequent attempts at activity caused a return of the symptoms. Five weeks before entry to this hospital he entered another outside hospital where his white-cell count was 19,000 and a gastrointestinal x-ray series showed no intestinal obstruction. The last 20 cm of the terminal ileum was not visualized although the barium had passed through it with ease. During the entire period after the operation the lower part of his abdomen had been distended and slightly tender, and he had attacks of gas-pain, and peristaltic rumblings and gurglings which sometimes lasted as long as an hour. He obtained no relief from his symptoms in spite of continued bed-rest and low residue diet. On several occasions his sedimentation rate and white count were elevated. About four weeks before entry he noticed in the region of the appendix scar the presence of a mass which gradually increased in size. During the few days before entry it enlarged rapidly and became somewhat tender. He had no nausea, vomiting, hematemesis or melena, but had lost about 20 lb in weight during his illness. He had not been exposed to tuberculosis except during his professional work, but he regularly drank raw milk. He had always lived in New England and had enjoyed the best of health. He had had catarrhal jaundice at the age of twenty and for some years had had some difficulty in starting his urinary stream. His past history was otherwise negative and his family history noncontributory.

Physical examination revealed a well-developed but quite thin man who did not appear to be acutely ill. The heart and lungs were negative. The blood pressure was 95 systolic, 60 diastolic. The abdomen was slightly distended, and in the right lower quadrant, medial to a well-healed scar, there were spasm and tenderness over an easily movable mass measuring 2 by 5 cm. There was no rebound tenderness, and peristalsis was normal.

The temperature was 100.5°F., the pulse 95. The respirations were 20.

The urine examination was negative. The blood showed a red-cell count of 4,500,000 with 85 per cent hemoglobin, and a white-cell count of 9700 with 78 per cent polymorphonuclears. The stool gave a 1+ guaiac test. A barium enema passed to the cecum slowly and with much difficulty, because of nervousness of the patient. The tip of the cecum was entirely obliterated by a large mass, and the terminal ileum failed to fill. A gastro-

intestinal x-ray series showed a normal small intestine. The terminal ileum passed around the mass at the tip of the cecum and was probably adherent to it. There was, however, no definite evidence of intrinsic disease in the small bowel.

A laparotomy was performed on the eighth day.

DIFFERENTIAL DIAGNOSIS

DR. WALTER E. GARREY. This is the story of a fifty-two-year-old man who for eight or ten years had four or five semi-solid bowel movements daily. Presumably this was the normal bowel habit of a somewhat irritable colon. He had a barium enema at some time during this period. We do not know how long before so we get no help in determining when the colon last appeared entirely normal. The real difficulty began four months before entry, when he had an episode of chills, fever, diarrhea and abdominal distention. This quieted down for about a week, and again, a month after that, he had another acute episode followed by a laparotomy, during which I shall assume a ruptured appendix was found and removed. We do not know anything about the pathology of the appendix, whether there was primary appendicitis or whether it was secondarily involved in some infectious process such as might result from ulceration and perforation at the base of the cecum with peri-appendicitis. Presumably microscopic slides, if they were made at the other hospital, were not available here.

At no time did the patient have any blood in his stools, and while he had five, large, soft stools in one postoperative day after the appendectomy, apparently he had no further bowel trouble. Then he began to have evidence of low-grade sepsis and abdominal gurgling and pain, with slight distention, symptoms which are pretty good clinical evidence of some degree of interference with peristalsis, or a slight degree of subacute obstruction.

One point about the x-rays interests me very much, and that is whether the x-ray people thought this mass was intrinsic or extrinsic to the bowel. May we see the films, Dr. Holmes?

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES. In all the films there is definite abnormality in this region near the tip of the cecum where you see an area unfilled by the barium. Moreover, the terminal ileum is displaced upward to form a rather sharp curve in all films, no matter what position the patient is in. The tip of the cecum is never filled, but in films taken with special reference to the tip you can see the outline of it. The edges are somewhat lobulated, particularly in this one area. The question that we raised was whether the lesion was

wholly in the cecum or partly in the cecum and partly outside. In other words, did he have an abscess outside the cecum which was pressing on it and which was displacing the terminal ileum or did he have a mass in the cecum itself which extended out and perhaps involved the ileum. As far as we could make out the disease did not extend into the ileum itself. The ileum is not blocked and the mucosal pattern in the ileum appears normal, so that a condition such as ileitis or tuberculosis would be unlikely. An inflammatory mass outside the cecum might explain this part of the defect but not the whole picture. He might have a lesion in the cecum and a mass outside. We felt confident that it was not entirely due to a mass outside, and that there must be an intrinsic lesion.

DIFFERENTIAL DIAGNOSIS (continued)

DR GARREY. It certainly is fair to say that regardless of the acute episode of appendicitis with perforation, he had underlying pathology which was intrinsic in the cecum. He has evidence of three months' difficulty after appendectomy. This is compatible with a lesion producing some slight degree of obstruction in this area. The question of whether the underlying pathology in the cecum was present at the time of the appendectomy and whether necrosis in the cecum with perforation was the primary episode and the appendix secondarily involved, I do not believe I can definitely answer. But it seems as if that might have been a very likely possibility. The absence of any change in bowel habits and the frequent soft stools are sufficiently characteristic of a mass in the region of the cecum with a slight degree of intermittent obstruction.

The physical examination is of considerable interest in that it tells us that this mass was movable at the time of the patient's entry here. If that is a correct observation I think it is of importance because I do not see how an inflammatory residual mass which followed a ruptured appendix could be a movable one. The presence of a movable mass in acute appendicitis with perforation has occasionally been noted, but I do not know of any instance where it was both movable and a residual abscess. The blood count is of considerable interest in that he did not have any great degree of anemia. In summary, I believe he has intrinsic disease of the cecum, that it has been present throughout the whole illness and that it now is secondarily infected, either as a result of the appendicitis or of a perforation, and that the mass is most likely to be caused by either tuberculosis or carcinoma. Other lesions that might possibly be considered are either amebic or nonspecific

granuloma of the cecum, the latter being the type which involves the small bowel and ileum, regional ileitis, or some rare tumor, but I do not see any definite evidence pointing to any of these lesions and I believe our differential diagnosis lies between tuberculosis and a scirrhous carcinoma of the cecum with, in each case, some secondary infection in or around the area. The fact that the mass is movable is in favor of tuberculosis. It seems to me that carcinoma of this long standing with resulting perforation probably would have become fixed in that time. Certainly the great majority of carcinomas of the right colon do bleed, or give some history of bleeding as evidenced in the stools or by the presence of anemia, which this man does not have. Dr Holmes mentioned the fact that the terminal ileum was not involved and we also might say that this is against tuberculosis, the most common tuberculous lesion being an ulcerative one involving both the terminal ileum and the cecum. However, hyperplastic tuberculosis of the cecum does occur without involvement of the terminal ileum. The man certainly should have a laparotomy. It is entirely possible that the surgeon, even after opening the abdomen and inspecting the tumor, may have had difficulty in deciding between tuberculosis and cancer. My first diagnosis is tuberculosis of the cecum, with carcinoma of the cecum as a second possibility.

CLINICAL DISCUSSION

DR CHESTER M. JONES. I saw this patient when he was in the hospital, and I think he illustrates a point that is important diagnostically. His history, I believe, should have given the clue to the diagnosis right from the start, had one localized his pain accurately. I went through the same line of reasoning as Dr Garrey did. It was difficult to get a proper history, because he was a surgeon and was convinced he had appendicitis. In talking about his "appendiceal abscess" the one thing he spoke of all the time was that he had umbilical pain, and pain nowhere else. He always limited it to an area about the size of a quarter, no larger. It was a striking localization and, on the basis of that, one had to decide what kind of terminal ileal or ileocecal disease he had. That pain is not the pain of appendicitis, to my mind. The five-year story of diarrhea preceding pain interested me and on the basis of that I thought we had to consider terminal ileitis or tuberculosis. I thought that he should be explored, and that the appendicitis at best was only a coincidence in a much more generalized process. I wrote down in the record that I thought he had disease of the terminal ileum with possibly some involvement of the cecum.

DR MARSHALL K. BARTLETT. When the abdo-

men was opened we found a mass in the region of the cecum. It was not adherent to the under side of the old appendix scar, but was adherent in the right gutter, and there were glands medial to the cecum which seemed to be broken down and perhaps caseous and yet the tumor itself suggested neoplasm. We were not sure of the diagnosis until we took a biopsy from one of the glands. Dr Mallory did a frozen section on this and told us it was carcinoma. On exploration of the liver we found it was full of metastatic disease. I have never seen one more so. In view of the inflammatory condition that he had had it is interesting to know that between the first and second stages of the operation the mass became adherent to the old scar and formed an abscess which drained spontaneously. There must have been a good deal of inflammatory reaction around the tumor at the time of operation.

PREOPERATIVE DIAGNOSIS

Abscess in the region of the terminal ileum and cecum

DR GARREY'S DIAGNOSES

Tuberculosis of the cecum
Carcinoma of the cecum?

ANATOMICAL DIAGNOSIS

Adenocarcinoma, grade III, of cecum, with metastasis to regional lymph nodes

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The main tumor mass was in the cecum but it had involved the margin of the ileocecal valve, so that was unquestionably the point of obstruction and as Dr Jones pointed out, explains the umbilical localization of the pain.

DR HOLMES May I call attention to the fact that the outline of this mass is lobulated on the inner surface. I think that is against tuberculosis. One should give that some weight in diagnosis. Sometimes the radiologist has an advantage over the surgeon even when he has the tumor in his hand. The radiologist is looking at the inside and the surgeon at the outside.

DR. GARREY Was the mass movable?

DR. BARTLETT It was. It is interesting that he had an acute perforated appendix. I have seen one other patient who had carcinoma of the cecum and had acute appendicitis some months before. That is a fairly rare combination. There are only a half dozen cases recorded.

THE ANNUAL MEETING

IN response to the call for the annual meeting of the Massachusetts Medical Society, more than one fourth of the members registered attendance. The record shows that 1387 applied for badges. Others were also present who did not register. This large proportion of the fellows was due to the attractive programs arranged by the officers of the Society and the several committees. There were included, besides the scientific subjects selected for addresses, exhibits of educational value, arrangements for bringing together the alumni of medical schools and plans for the entertainment of non-medical groups.

Sixty doctors competed for the golf prizes and 204 ladies registered as guests of the Society.

The scientific and commercial exhibits were well arranged with qualified persons in charge. The

interest shown in these displays must have pleased those who devoted so much time to preparing and arranging them.

The Section meetings were well attended. The experiment of last year of having one full day given to bringing together general practitioners and recognized authorities in the special fields of practice for the discussion of medical problems, was repeated. The large attendance apparently indicates the advisability of the continuance of this plan.

On Tuesday evening, preceding the Shattuck Lecture, Dr. Thomas Parran, Surgeon General of the United States Public Health Service, spoke of the work and aims of this department. After giving an account of the great accomplishments in the fields covered, he warned the profession that further advances in public health work will depend, to a large extent, on the loyal co-operation of physicians and all other agencies interested in promoting the health of the people of this country. Following Dr. Parran's address, Dr. David Riesman, emeritus professor of clinical medicine and professor of the history of medicine at the University of Pennsylvania School of Medicine, delivered the Shattuck Lecture, in which he gave a history of the discovery of many new diseases by the physicians of this country. This was a scholarly address made especially interesting by the speaker's ability to present the facts in an attractive setting of well-chosen phrases. All persons interested in medical history will enjoy reading the paper which will appear soon in the *Journal*.

On the evening of the second day 325 fellows and guests met for the annual banquet. The after-dinner speaker was Mr. Norman MacDonald, executive secretary of the Massachusetts Federation of Taxpayers' Associations. In selecting the speaker for this occasion the President evidently felt that the scientific programs of the meeting were so broad and inclusive that it would be well to divert attention from medical subjects to a topic of a non-medical nature, and which would be of common interest to all people of this state. The speaker presented an array of facts pertaining to taxation and the burdens imposed on the average citizen.

thereby, emphasizing the danger which he believes is impending under financial and economic theories already on trial. He evidently wished to create in the minds of the intelligent portion of the population a purpose to pay more attention to the economic uncertainties that are associated with the depressions and recessions now prevailing.

The audience was very much impressed by the facts and arguments submitted.

THE COUNCIL MEETING

While the scientific programs were being carried on, the stated meeting of the Council was in session on the second day. This meeting was called to order by the President at 10.30 a. m. with 232 present. The reading of the records of the February meeting was dispensed with because of previous publication in the *Journal*.

The President presented brief biographical sketches of the lives of those councilors who had died since the last meeting and the Council rose and stood for a brief period in tribute to the memory of these departed fellows.

All the district societies were found to be represented by nominating or alternate nominating councilors and this group was directed to retire and consider names to be presented for the positions of president, vice-president, secretary, treasurer, and orator for the ensuing year. After a brief interval the report of this committee was submitted and the following designated persons were placed in nomination: For President, Channing Frothingham, for Vice-President, Albert Warren Stearns, for Secretary, Alexander Swanson Begg, for Treasurer, Charles Shorey Butler, for Orator, Elliott Proctor Joslin. No nominations coming from the floor, the Secretary was authorized and directed by vote to cast one ballot for the persons nominated. This was done and the nominees were elected.

References to the re-elected officers have been published in the *Journal* previously.

Both Dr. Stearns and Dr. Joslin have national reputations. Dr. Stearns was born in 1885 and graduated from the Tufts College Medical School

in 1910 and occupies the positions of Dean and professor of psychiatry in this school.

Dr. Joslin was born in 1869 and graduated from the Harvard Medical School in 1895. For many years he has devoted a large proportion of his time to the Diabetic Clinic at the Deaconess Hospital in addition to his position of clinical professor of medicine at the Harvard Medical School.

The usual routine business relating to membership and the appointment of committees was transacted without discussion. Dr. Lund, chairman of the Committee on State and National Legislation, gave a detailed account of the work of his committee. Although disappointing in one particular this report was in the main encouraging. The opponents of sound medical education succeeded in getting the legislature to postpone the operation of the law which originally gave to the authorities power to pass on the standing of medical schools from which graduates apply for registration to practice medicine in Massachusetts. The report when published in the Proceedings of the Council will give the essential facts relating to legislation of interest to physicians.

The proposed amendment to the by-laws providing for the method by which delegates to the House of Delegates of the American Medical Association are to be elected was the subject of an animated discussion.

A majority and a minority report of the committee in charge of preparing a draft of the procedure were before the Council. A minor change in the wording of the majority report brought unanimous support. This, with all the other amendments to the by-laws (copies of which had been sent to all members of the Society), was approved by the Council and forwarded to the Society for final action.

The problems relating to prepaid hospitalization which have been studied by the Committee on Public Relations came up for discussion in an attempt to secure proper recognition of the standing of all classes of doctors in this plan for hospital service. This subject was again referred to the Committee on Public Relations for further

consideration and conference with all parties in interest

Other subjects considered will be found in the report to be published. The work of the Council was prosecuted without undue delay and was completed soon after one o'clock when the meeting adjourned for the Cotting Luncheon.

After the completion of the Section meetings at noon of the third day the Annual Meeting of the Society was called to order by the President.

The Secretary reported the number of admissions to the Society for the year. These exceeded the number removed from the membership list by 122, bringing the number of members now enrolled to 5298.

Resolutions were submitted from the floor emphasizing and endorsing the action of the Council Meeting in February relating to the reappointment of Dr. Henry D. Chadwick to the position of Commissioner of Public Health. These resolutions were unanimously approved and have been forwarded to His Excellency Governor Hurley and the Governor's Council.

The several amendments to the by-laws which were forwarded by the Council were adopted by the Society. Copies of these amendments had been sent to all fellows of the Society.

The sentiments of regret at the retirement of Dr. David Cheever, chairman of the Committee on Ethics and Discipline, Dr. David Blakely, chairman of the Committee on Membership and Finance and Dr. Arthur Marsh of the Committee on State and National Legislation as expressed by the President were endorsed by the Society. These three fellows have served the Society for many years with fidelity and devotion to the duties of the several positions occupied.

In his annual address the President reported that the financial condition of the Society is sound, due to the conservative administrations of the Committee on Finance and the Treasurer. References to controversies existing in organized medical bodies, the survey of the inadequacies of medical care, hospital service and other important matters before the profession showed his full under-

standing of the need for careful attention devoid of prejudice and ill-feeling.

The last official act of the Society was to listen to the Orator, Dr. Allen G. Rice, of Springfield. He discussed the surgical practice of former years as compared with that of the present, paying tribute to the quality of those who worked more or less single-handed and had to depend on sound thinking, manual dexterity and experience rather than the equipment of modern clinics for their success. This paper¹ will be enjoyed by all who will read it.

So far as this brief and sketchy reference to the successful meeting is concerned it is intended simply to arouse such interest as will lead to a careful examination of the reports of the Proceedings and the reading of the papers presented before the Sections.

Although the President expressed appreciation of the work done by the several committees no one other than those engaged in planning and carrying on the details of the many activities can realize the time and energy expended. Their best thanks will be found in the good attendance, the general pleasure expressed with the arrangements and service and the disappointment of the fellows who were unable to attend.

DR. SIGMUND FREUD

Many physicians are watching Vienna with interest as news comes of what is happening in that medical center. Of special interest is the fate of Dr. Sigmund Freud.

Freud started his medical career in the field of medical investigation, not of psychotherapy. But from the beginning the leading trend of his future work was revealed to consider insight and knowledge as the way to help and cure.

His first interest was given to physiology. One of his publications, a monograph on the effects of the coca plant, the medicinal use of which was unknown at this time, gave the cue for the discovery of cocaine as a local anesthetic. Later he turned to the anatomy and pathology of the brain, and this line of research brought him for the

first time face to face with the problem of psychoneurosis

This was the period—the eighties of the last century—when medicine with the help of many great discoveries had definitely established itself on a scientific basis. Yet the study of psychoneuroses and psychoses, due to their inaccessibility by the new methods and instruments, was still in the stage of a crude empiricism. They represented a dark corner which few cared to investigate, since there were so many important and fascinating discoveries to be made by studying organic processes with the help of the test tube and the microscope.

Charcot represented the most important exception. He had studied intensely the symptomatology of hysteria and furthermore had demonstrated that the phenomena of hypnosis, which hitherto had been regarded as sheer humbug, were real and deserved serious attention. To Charcot, then, Freud went and became his disciple at the famous clinic of the Salpêtrière in Paris and later on studied under Bernheim and Liébault. But the turning point in his career did not come until he learned that hypnosis could be used not only to give commands, which by reasons unknown were obeyed by the hypnotized patient, but also for the exploration of an otherwise hidden part of the mind.

This new knowledge came to him through Breuer, an eminent physician in Vienna, who had, somewhat by accident, discovered that a hysterical patient of his was able during her hypnotic state to tell him the meaning and origin of her symptoms, by revealing these secrets she had step by step got rid of her symptoms. On the basis of this and some similar experience a "cathartic" method was evolved. The joint work of Breuer and Freud was published under the title *Studies in Hysteria*.

Neither the first incomplete theory nor the mysterious and undependable technic of hypnosis was satisfactory to Freud. He then went on the lonely way of original and independent research. It led him to the dropping of hypnosis and replacing it by the more difficult and complicated but

far more adequate technic of "free associations." The importance of the "unconscious" for psychopathology, the dynamism of repression and the influence of infantile sexuality were thus brought to light.

We can distinguish three periods in Freud's life-work. In the first he developed and formulated his fundamental theories, explored the unconscious and demonstrated the role which it plays not only in psychoneurosis and psychosis but also in phenomena of pathologic character that yet belong to the working of the normal mind, such as the dream, and the so-called "psychopathology of everyday life." The crowning piece of this period is the *Interpretation of Dreams* which was published five years after its completion, when every part of it had stood the test of experience.

In the next period Freud showed in different ways the fertility and also the revolutionizing influence of the new science, these were not limited to the field of psychopathology. In a series of detailed case histories he demonstrated the mechanism of the struggle between instinct and repression, and the way in which the various forms and stages of this struggle produce the different forms of hysteria, obsessional neurosis, schizophrenia and paranoia. On the other hand he turned his attention to the social side of the mind and studied esthetic, sociologic and ethnologic problems from a new angle, namely from the point of view how much the beliefs, mass phantasies and institutions which man has evolved and accumulated in the course of the many centuries of his cultural development have been stimulated and influenced by unconscious tendencies and conflicts. The two representative works of this period are the *Introductory Lectures* and *Totem and Tabu*.

The third period is characterized by a still more and more widening concept of psychoanalysis. Without neglecting its clinical aspects Freud lifted it to a new level, the interest was not any longer narrowed down to the unconscious, but comprehended also the structure of the "ego." What had been an approach to certain problems of

psychology from the side of psychopathology became the beginning of a new psychology. In *Beyond the Pleasure Principle* the attempt was made to link up the laws ruling the human mind, especially its instinctual processes, with the principles of biology. In a series of books Freud probed the value and the function of the most important cultural achievements. *Civilization and Its Discontent* is the most remarkable of these works which — although Freud himself would protest against such a designation — must be termed deeply philosophic.

As shown even in this short sketch, Freud's interests and knowledge are widespread, comprising an astounding number of subjects. Besides his great contribution to psychiatry, besides his practical therapeutic work to which he devoted nine hours daily he found time to study many other scientific disciplines which he used for his work, and to know and enjoy the masterpieces of literature of the past as well as of his own day. Not satisfied with all that, he studied with special interest the history and civilization of old Egypt and made collecting its antiquities his hobby.

Freud has always led a quiet and retired life, given up entirely to his scientific and scholarly pursuits, far away from the strife of politics. While his ideas were heatedly discussed all over the world, while his name became a byword of reproach, he avoided all controversy and resisted every effort to let himself be drawn into the limelight of publicity. He has been continually surrounded by the love of his family — he had six children, of whom the youngest, Anna, became associated with his work — and the devotion of his nearest disciples to whom he has shown an unflinching loyalty. Outside of this circle he has but few friends, but among them are men like Thomas Mann and Romain Rolland.

He had lived in Vienna since early youth, inhabiting for nearly half a century the same rooms. Now, on the eve of his eighty-third year, he has had to leave his old home in search of a new country. We believe that he will take with him his unexhausted vitality and his unbroken strength of mind.

330 Dartmouth Street
Boston

CASE HISTORY No 76 BLEEDING AT SEVEN MONTHS, RUPTURE OF THE UTERUS

Mrs. G. S., a white multipara, para six, aged thirty-seven, was first seen when she visited the prenatal clinic on October 20, 1937. She had been referred by a Community Health nurse who reported a trace of albumin in the urine.

Her family and past histories were negative. Catamenia began at fourteen, were never regular, frequently occurring as often as fifteen but never going over twenty-eight days, and lasting four days with no unusual discomfort. Her last period was July 28, making the expected date of confinement May 4. In 1923 she was delivered of a full-term, 7 lb. child, which is living, and in 1926 she had a living child by cesarean section at term. Other cesareans were done in 1924, 1927, and 1935, all at six months because of toxemia.

The patient weighed 224½ lb. Her teeth were in fair condition, her thyroid showed no enlargement, and there was no general glandular enlargement. The heart was normal in rate and rhythm. The lungs were clear and breath sounds were normal. The blood pressure was 158 systolic and 124 diastolic. The abdomen was fat and showed four separate scars extending from the symphysis pubis to the umbilicus or above. There was diffuse weakness in the region of the lower end of these scars. The abdomen showed no masses or tenderness. Vaginal examination showed the uterus to be about the size of a three-months' pregnancy. It could not, however, be felt through the abdomen. A voided specimen secured at this time showed a trace of albumin but nothing abnormal otherwise.

The patient was seen in the prenatal clinic six times and after the first visit presented a similar picture on each occasion. She had no complaints. Her weight was increasing gradually, her blood pressure had come down to within normal limits without treatment and was recorded as averaging 110 systolic and 60 diastolic. She showed no toxic symptoms and was reported to be in good condition. The urine examination on each of these occasions showed a trace of albumin, but these were

A series of selected case histories by members of the section will be published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the section.

in every instance voided specimens. No other abnormal findings are recorded.

On March 4, when about thirty-two weeks pregnant, the patient commenced to have some nausea and moderately severe pain in the lower abdomen. She described this latter as radiating toward both lower quadrants. Thinking that this was indigestion she took some baking soda, and after that vomited twice. During this time she also commenced to have a pain in the lower back. She arrived at the hospital at 9.30 complaining of abdominal pain which was mostly in the right-lower quadrant. Because of her obesity the uterus was difficult to outline with any precision and no other structures could be felt in the abdomen. There was definite tenderness which was apparently located in the left side of the uterus. Shortly after admission to the hospital she vomited again. A catheter specimen of urine showed a large trace of albumin. Her blood pressure was 108 systolic and 70 diastolic, her pulse was 80, her temperature 98°F, and respiration 16. A white count was 16,600 and her hemoglobin was 74 per cent Sahli. Examination of the blood showed a nonprotein nitrogen of 35 mg., a uric acid of 4.2 mg per cent, chlorides of 270 mg per cent and a carbon-dioxide combining power of 36 per cent. Rectal examination produced moderate discomfort but no acute pain. There was no present-ing part in the pelvis.

Shortly after admission to the hospital the patient began to pass a small amount of bright-red blood by vagina. The attending physician saw her shortly after 11 o'clock at which time her blood pressure and pulse rate were about as on admission, but the abdominal tenderness was definitely increasing and included both sides of the uterus. It was thought at this time that she had had a premature separation of the placenta because of the abdominal findings, the trace of albumin in the urine, her history of repeated toxemias and the small amount of bleeding which she had had. In view of her repeated cesarean sections, it was decided to do another at once. During the preparation of the operating room the patient collapsed. Her blood pressure fell to 70 systolic, and she became pulseless. It was then obvious that she was bleeding severely and that she had probably ruptured her uterus.

The patient was anesthetized with cyclopropane. The abdomen was prepared with ether and half-strength iodine, and a median incision was made. On coming down to the peritoneum there was the bluish appearance characteristic of blood in the abdominal cavity. On opening the abdomen a large quantity of fresh and old blood was found. The uterus had ruptured, the placenta was com-

pletely detached, and the membranes were bulging through the rupture. No attempt was made to deliver the sac in toto, but the fetus, placenta and membranes were removed as quickly as possible and the abdominal cavity sponged free of blood. It was then found that the uterus was well contracted but showed a rupture running from the fundus down to the lower uterine segment. There were so many lateral adhesions to the uterus from the preceding operations that it was thought unwise to attempt hysterectomy. The uterus was closed with a continuous suture of No 2 chromic catgut. This controlled the bleeding very well. A second layer of continuous No 2 chromic catgut was inserted on the serous surface. The patient was then sterilized by the Madelener method. The abdomen was closed in layers in the usual manner, and stay sutures of heavy silk were inserted.

During the operation attempts had been made to give the patient intravenous glucose solution, but these were unsuccessful because the veins were collapsed. At the close of the operation an arm vein was exposed and a cannula inserted. Ten per cent intravenous glucose was started and the patient's condition commenced to improve at once. Her husband and a brother had been typed for transfusion but were incompatible and a transfusion of 500 cc of citrated blood from a professional donor was given shortly after the intravenous saline. This improved the patient's condition still further, and she was returned to bed in moderately good condition. There she was placed in medium Fowler's position and oxygen was started through an intranasal tube because of the reduced oxygen-carrying power of her blood.

Her highest temperature was 101.2°F, March 5, with a pulse rate of 120 and respirations of 48. The patient showed some cyanosis when the oxygen was discontinued. An x-ray plate of her chest, taken in bed, showed involvement of the upper lobe of the right lung. This was diagnosed as early pneumonia. She was more comfortable with the nasal oxygen than without it. The abdomen showed no distention and no tenderness except in the midline at the site of the incision. She was given 1000 cc more of 10 per cent glucose solution intravenously and a second transfusion of 500 cc of citrated blood. Her hemoglobin before the second transfusion was 67 per cent and the red count was 2,850,000.

On March 6, her highest temperature was 101.4°F, her pulse rate 108, with a drop in respiration to 32. Her blood pressure at that time had come up to 118 systolic and 68 diastolic. The patient was taking fluids by mouth and there was no nausea or vomiting. Her breathing was

much easier and her color was better than on the previous day. The abdomen showed no tenderness or spasm and very little distention. An effort had been made to secure sputum for pneumococcus typing, but the only specimen obtained was small and blood-streaked and might well have come from around the tube in the nasopharynx. A blood count showed 10,000 white cells, and 3,410,000 red cells.

On March 7, the pulse, temperature and respirations were about as before. Her general condition continued good and she commenced to pass gas by rectum. She was taking a soft-solid diet. This continued until March 10 at which time a second x-ray of her chest showed considerable improvement in her lung condition. On March 13 her temperature had dropped to 99.6°F, her pulse rate to 96 and her respirations to 20. Her bowels were moving and she was on a full diet.

From March 13 to 16 her evening temperature averaged 100°F. During this period her pulse rate was continuously between 80 and 90 and her respirations averaged 20. When the dressing was done on March 16 the abdominal incision was found to be clean and healing well. The skin sutures and stay sutures were removed at that time.

On March 19 the patient was allowed to put her feet out of bed and on the following day she was allowed to sit up in a chair. On March 23 she was discharged from the hospital. At the time of discharge the abdominal wound was dry, clean and well healed. There was no abdominal tenderness. On bimanual examination there was no pelvic tenderness and the uterus was well involuted. The cervix was posterior and its mobility was limited. The vaults were clear. Because of the fact that the patient had shown a large trace of albumin in every specimen of urine examined since her delivery and because the sediments had shown leukocytes ranging from 2 to 18 per high-power field, she was discharged to the medical clinic for follow-up work on her kidney condition. At the time of discharge her blood pressure was 112 systolic and 72 diastolic, while her blood count showed 11,400 white and 4,720,000 red cells, with a hemoglobin of 81 per cent (Sahli).

Comment. The commonest site of rupture of the pregnant uterus is through the scar of a previous cesarean section. This is one of the reasons why an initial cesarean should be undertaken only after serious thought. It is a rule in many hospitals that no cesarean section shall be performed without consultation. This consultation, of course, should be held with an obstetrician. Spontaneous rupture of the pregnant uterus does occur even though not

associated with the scar of a previous cesarean section, but these ruptures always take place during active labor. While it is perfectly possible to have a complete separation of the placenta at seven months without previous pathology, the fact that this patient had had four previous cesareans should have been sufficient reason for the obstetrician in charge to have made the correct diagnosis long before the patient was in extremis and before the abdomen was opened. The decision not to take this uterus out in this particular case was probably a very wise one and sterilization certainly was indicated and justifiable.

INFANTILE SCURVY

Although the first description of scurvy as a disease appeared in 1260, it was not until 1668 that it was definitely described as occurring among infants. This disease, which results from a deficiency in vitamin C and is characterized by generalized bleeding, does not, under ordinary circumstances, occur in normal breast fed babies provided the diet of the mother contains enough vitamin C. However, should the mother's diet be poor, her milk will not contain the necessary amount of this vitamin and as a result the baby will develop the disease. It is for this reason that doctors often add some substance containing vitamin C, such as orange juice or tomato juice, to the diet of the nursing infant. Although the introduction of pasteurized and boiled milk as a precaution against the development of such milk-borne infections as tuberculosis and typhoid fever undoubtedly removed these dangers from the infant, it was followed by an increase in the incidence of scurvy as heating destroys vitamin C. Therefore, it is important that some substance containing this vitamin should be added to the diet of the artificially fed infant. Since boiling or prolonged heating destroys the vitamin, it naturally follows that orange juice should be neither boiled nor heated, nor should boiling water be added to the juice. The young mother who has been taught that milk, water, bottles, nipples, and so forth, must all be sterilized may easily assume that orange juice should be heated or boiled and as a result the vitamin content is destroyed and the baby develops scurvy.

Age is a definite factor in the occurrence of scurvy, the majority of cases develop during the latter half of the first year and the first half of the second year of life. After the age of one year, scurvy becomes increasingly less common, for at this period the infant's diet usually includes various foods which contain vitamin C. Season also tends to exert some influence on its occurrence, it is more frequently encountered during the winter and spring months when the herds may not be receiving fresh fodder, thereby reducing the vitamin content of the milk.

In the majority of instances the symptoms of scurvy do not appear suddenly but gradually develop over a period of several weeks until finally the typical signs of the disease are present. Early in the course of the disease the infant becomes fretful, irritable and pale, and does not like to be moved. This irritability is often first observed when the lower extremities are being handled and is due to pain resulting from bleeding beneath the outside covering of

A Green Lights to Health broadcast given by Dr. R. Cannon Eley on Wednesday May 25 and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

the bones. Any movement produces this pain, which may become so severe that the baby will begin to scream and cry from fear when anyone comes near it. This tendency to bleed is usually more likely to occur about the joints, such as the knees and ankles, than along the shaft of the bone and may cause the joint to become three or four times its normal size. In severe cases, these hemorrhages often cause the growing end of the bone to become separated from the shaft thus retarding the process of normal growth. As a result of the painful joints, the infant takes a rather characteristic frog-like position, lying motionless, flat on its back, with the thighs drawn upward, the knees bent and the legs turned outward at the hips. The gums are red, swollen, bleeding and extremely painful making it increasingly difficult for the baby to nurse, and if the teeth have been cut, dark hemorrhagic blisters or areas may appear at the point where the teeth come through the gums. Bleeding behind the eyes or around the eye socket is frequently seen and may not only cause the eye to protrude but may also give it the appearance of the well known 'black-eye'. There are often many 'black and blue' spots on the body suggesting that the infant has met with some fall or accident, and in some instances blood may appear in the urine and in the stools. As one might expect, these changes are accompanied by fever, which is often as high as 102 or 103°F, elevation in blood pressure and a more rapid pulse rate. However, in view of the fact that the present-day infants' diet is more liberal than those formerly employed, few babies suffer from complete lack of vitamin C and the more severe and advanced forms of the disease are, therefore, less frequently seen today than they were several years ago.

The diagnosis of scurvy seldom presents any great difficulty, the story of a diet inadequate in its vitamin C content and the general appearance of the baby suggest the possible presence of the disease. Even if the signs and symptoms of the well-advanced case are not present, one may employ suitable x-ray and laboratory studies which will settle the diagnosis. It is well known that an x-ray examination will show early changes in the bones that cannot be detected by the usual physical examination. Recently, chemical tests have been so perfected that the exact amount of vitamin C within the blood and the urine can be estimated, thus making it possible to discover that a baby is developing the disease long before any physical signs or symptoms are present.

Scurvy can be prevented more easily than it can be cured. Therefore, in considering its treatment we should first consider its prevention. Every infant who is fed upon boiled, pasteurized, evaporated or dried milk should also receive some substance containing vitamin C, as early as the first or second month of life. Even if the baby is nursed and the mother is receiving an adequate diet, the addition of this vitamin as a precautionary measure is worth while. Orange juice is probably the most convenient source of vitamin C and should be given in increasing amounts until the baby is taking approximately 2 oz. each day. Tomato juice offers another good source but when used should be given in amounts twice that of orange juice. Lemon or grapefruit juices may also be given but, due to their taste, are less readily taken by the baby. There are, however, some infants who refuse to take either orange or tomato juice and another group who develop rashes or other skin troubles after taking them. What can be done to prevent scurvy from developing among this group of babies? Within the past two years, vitamin C has been separated in its pure form and may be obtained from pharmaceutical houses in the form of a pill, each pill containing 25 mg., or the same amount of the vitamin C as that present in one large or two small

oranges. One of these tablets given each day to the baby will prevent scurvy. Furthermore, the price is often less than that of fresh fruit so there is really no excuse for the presence of scurvy from a financial viewpoint.

The treatment of the disease is usually simple and effective, only requiring the administration of an adequate amount of vitamin C to the baby. However, in severe cases, care should be exercised not to give too large amounts as there is reason to believe that excessive quantities may not always prove to be without danger. The results of this treatment are not only prompt but almost spectacular. Within twenty-four hours the disposition improves, the tenderness begins to disappear, joint enlargements go down, gums stop bleeding and appetite improves. However, in severe and advanced cases with poor nutrition, or in cases with other diseases such as pneumonia, death rather than recovery may be the result. Scurvy is a preventable disease. Why let it occur?

Q What is the best way of preventing scurvy?

A. The best means of preventing scurvy is by education of the public to the importance and significance of vitamin C in the infants' diet. This antiscorbutic substance is not present in pasteurized, boiled or dried milk, so it should be added to the food in some suitable form, such as orange juice or tomato juice. Recently this vitamin has been prepared commercially in the form of a tablet which is not expensive and which can be given to those infants who refuse or cannot tolerate fruit juices containing vitamin C.

Q Are scurvy and rickets due to the same vitamin deficiency?

A. No. Rickets results from a deficiency in vitamin D which is present in cod liver oil, scurvy results from a deficiency in vitamin C. However, it is not uncommon to see a baby suffering from the two diseases at the same time, for a diet that is deficient in one vitamin is often deficient in others. This is clearly shown by the fact that in a series of 314 babies with scurvy 36 were also suffering from active rickets.

Q Is scurvy primarily a disease of the poor?

A. Scurvy may occur among the rich as well as the poor if the vitamin C requirements are inadequate.

Q Is scurvy considered a common disease?

A. The series of 314 cases, previously mentioned, was seen and treated at the Infants and Children's hospitals in Boston from 1926 through 1935.

Q Did all the babies recover?

A. No. Three died from pneumonia and one died from tuberculosis.

Q At what age is the disease most likely to develop?

A. As our statistics showed, 276 of the patients were from six to twelve months of age.

Q What was the most common symptom of the babies studied in the review?

A. The majority of the babies were suffering from well-advanced scurvy, and the chief disturbance was pain when the babies' legs were even gently moved.

Q Do the hospital records show that there is as much scurvy today as there was ten years ago?

A. In 1926, there were 32 cases, in 1935 there were 39 cases. These figures seem to show that there was very little, if any, change in the amount of scurvy during the ten-year period. This can only be due to improper feeding of children, for we know what causes the disease and we know how to prevent it as well as how to cure it.

MISCELLANY

EARLY DIAGNOSIS OF TUBERCULOSIS

One measure of the efficiency of the tuberculosis campaign is the percentage of tuberculosis patients who reach the sanatorium in the minimal stage. The most extensive study yet made indicates that only about 16 per cent of sanatorium admissions are classified as minimal cases. There are several reasons why this number is so small. Two of them, namely delay in seeking advice and delay in making the diagnosis after the patient has visited the doctor, have been analyzed by Monte and Blitz (New Orleans M & S J 90 468-475, 1938) who reviewed the experiences of 300 patients under treatment in the Dibert Memorial of Charity Hospital in New Orleans.

Of the 300 white adult patients studied, less than 2 per cent were classified as in the minimal stage, 45 per

the patient to seek medical attention. In over 50 per cent of the cases, this symptom complex, although being the incentive for the visit, had been present for many months and undoubtedly was associated with constitutional symptoms of some degree. Yet these patients insisted that the accompanying symptoms were of little consequence and were not serious enough to interfere with their daily routine. True, lesions may be present in the lung parenchyma without any obvious symptoms as revealed in 5 cases reported wherein symptoms of subjective importance were absent, while roentgenological study revealed active pulmonary tuberculosis. Four of these cases were minimal, the fifth being moderately advanced. This does not necessarily imply that the number and duration of symptoms can be strictly correlated with the stage of the disease, for some of the patients volunteered the information that hemoptysis or pleurisy had been the initial symptom,

This chart is based on a study of the experience of 361 patients with tuberculosis, made by Ruth A Sedar, Social Research Series No 5, National Tuberculosis Association

cent in the moderately advanced and 53.3 per cent in the far advanced stage. Ages ranged from sixteen to seventy-eight years. Seventy-six per cent of the women and 51 per cent of the men were under thirty-five years of age.

A history of tuberculosis in the immediate family was found in 28 per cent of the series. A striking feature was that almost twice as many women as men admitted a history of tuberculosis in the family. Evidently contact with the tuberculous patient in the home is more frequent among female members of the household for they usually have the responsibility of caring for and nursing the sick.

Prior to their admission to the hospital, the diagnosis was established in 61.6 per cent of the cases, was suspected in 19.6 per cent and was not made in 18.6 per cent. The high incidence of 'suspected' cases is accounted for by the limited facilities of the average practitioner in Louisiana, and the authors believe that if the roentgen ray and laboratory aids were more widely used, diagnosis would be established in a greater percentage of cases.

The responsibility for delay in diagnosis when symptoms are present must be shared alike by the patient and the attending physician. Symptoms of a mild nature often seem negligible in the patient's estimation and thus he postpones medical consultation until more severe symptoms appear. In 2 of the 300 patients, the duration of symptoms before visiting the doctor averaged two months, and two more months elapsed before the diagnosis was established. At the end of the scale are 90 patients who delayed almost ten months before consulting the doctor and then suffered a further delay of about twelve months before the diagnosis was established.

Cough and expectoration were the most prominent initial symptoms, and these also most frequently caused

and immediate skiagrams revealed either moderately or far advanced pulmonary tuberculosis.

Of all the symptoms listed, there is little variation between the initial and presenting symptoms, with the exception of hemoptysis. As an initial symptom it was present in 9.6 per cent of the cases, whereas 22.7 per cent sought medical aid because of blood spitting. This difference in percentage indicated that although these patients had had previous symptoms a pulmonary hemorrhage was regarded with enough fear to prompt them to visit a physician.

Fever and night sweats, a combination of symptoms which in most textbooks is given a ranking position in the diagnosis of tuberculosis, were found with comparative infrequency in this series. As initial symptoms they were present in only 3.6 per cent, and as presenting symptoms, in 5 per cent of the cases.

The authors offer the following explanations for the failure in diagnosis on the basis of presenting symptoms:

Cough and Expectoration. The diagnosis was not suspected in 38.3 per cent of this group. This was probably due to the tendency on the part of physicians to diagnose prolonged or recurrent coughs as chronic bronchitis or chronic sinusitis.

Loss of Weight and Fatigability. Tuberculosis was not suspected in 50 per cent of these cases. Such diagnoses as nervousness, nervous breakdown, overwork, overindulgence in alcoholics and tobacco, dissipation, and chronic debilitating diseases were offered by the attending physician.

Hemoptysis. Blood spitting, which has been known throughout the centuries as one of the pathognomonic symptoms of phthisis, was a frequent source of error in

diagnosis Although the percentage of failure (22 1) was less than that in other groups of symptoms, it is still too high. The absence of positive physical findings on examination of the chest probably accounts for such diagnoses as ruptured blood vessel, irritation of throat, and bleeding from nasopharynx.

Pleurisy When a patient is seen only once, it is difficult to make a diagnosis unless a suspicion of tuberculosis is ever present in the physician's mind and the patient is urged to return for further observation after the acute attack subsides. Idiopathic pleuritis, though it may be accepted by the majority of physicians, should never be used as such until a sufficient interval has elapsed and the lung has remained clinically and radiologically negative. Failure to recognize this has resulted in 40.9 per cent mistaken diagnoses.

Fever and Night Sweats Climatic and endemic conditions undoubtedly are the source of confusion as regards this symptom complex. With the high incidence of malarial infection in Louisiana, it is little wonder that a number of patients were treated previously with quinine, plasmochin or Atebrine. This group leads all others in percentage of error, 73.3 per cent being neither diagnosed nor suspected.

Grippe The diagnosis was missed in 40 per cent of the group presenting symptoms ordinarily attributed to an acute respiratory infection with or without physical signs of a pneumonitis. The constant occurrence of 'flu epidemics and the failure to realize that bed rest over a short period may render a tuberculous patient asymptomatic are the natural sources of error. As in any of the aforementioned symptom complexes, suspicion of tuberculosis is of prime importance. — *Tuberculous Abstracts* June, 1938

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR MAY, 1938

DISEASES	MAY 1938	MAY 1937	FIVE YEAR AVERAGE*
Anterior poliomyelitis	0	1	6
Chickenpox	1129	1579	1134
Diphtheria	8	21	43
Dog bite	1107	1223	1066
German measles	74	259	2269
Gonorrhea	366	486	488
Lobar pneumonia	475	434	380
Measles	1350	2953	3800
Meningococcus meningitis	4	31	15
Mumps	977	747	953
Paratyphoid B	20	61	17
Scarlet fever	1525	976	1081
Syphilis	507	534	441
Tuberculosis pulmonary	178	267	324
Tuberculosis other forms	13	20	39
Typhoid fever	1	4	10
Undulant fever	2	1	3
Whooping cough	478	1220	817

*Based on figures for preceding five years

RARE DISEASES

Diphtheria was reported from Boston, 2, Lexington, 1, Salem, 2, Watertown, 1, Worcester, 2, total, 8

Dysentery bacillary, was reported from Cambridge, 1, Danvers, 9, Springfield, 4, Wellesley, 1, Woburn, 5 total, 20

Meningococcus meningitis was reported from Boston, 1, Haverhill, 1, Quincy, 1, Worcester, 1 total, 4

Paratyphoid B was reported from Brookline, 9, Braintree, 1, Fall River, 8, Newton, 1, Sharon, 1, total, 20

Pfeiffer bacillus meningitis was reported from Beverly, 1, Gardner, 1, Worcester, 1, total, 3

Septic sore throat was reported from Amherst, 2 Beverly, 3 Boston, 8, Cambridge, 1, Everett, 1, Greenfield, 1,

Salem, 3, Southbridge, 1, Sturbridge, 1, Wakefield, 1, total, 22

Trichinosis was reported from Springfield, 1

Typhoid fever was reported from Boston, 1

Undulant fever was reported from East Bridgewater, 1, Millis, 1, total, 2

Diphtheria was reported at a record low figure.

Scarlet fever, mumps and lobar pneumonia were reported above the five year average.

The reported incidence of tuberculosis (other forms) showed record low figures both for this and any other month ever recorded

The reported incidence of German measles showed record low figures

Chickenpox, whooping cough and measles were reported below the five year average.

Except for May, 1934, which was equalled, meningococcus meningitis showed record low incidence.

The incidence of undulant fever was not remarkable.

The figures for pulmonary tuberculosis showed record low incidence.

Paratyphoid B fever continued to be reported at a high figure.

Typhoid fever showed record low incidence.

The reported incidence of dog bite was maintained at a fairly high figure. Several cases of animal rabies were reported throughout the state. Previously reported foci in Westborough, Malden, Sutton and Andover were active. A new focus was noted in Grafton.

CORRESPONDENCE

HOW DeQUINCEY BECAME AN OPIUM ADDICT

Among the books on DeQuincey none is more interesting than the biography by Horace Ainsworth Eaton (Oxford University Press, 1936)

Eaton tells us that in 1804 DeQuincey came up to London, from Worcester College, Oxford. He took lodgings, and for some reason not explained, omitted the complete washing of his head in cold water, which he was accustomed to take. He was suddenly seized with a most violent toothache, which he attributed to this omission. 'He jumped out of bed and plunged his head in a basin of cold water, and with hair thus wetted went to sleep'. The next morning he suffered the most excruciating facial neuralgia, we are told, which kept up for three weeks. Nearly frantic with the pain he walked out one day and met a college acquaintance. DeQuincey told him of his constant misery and the student recommended that DeQuincey take opium for the pain. Near the Pantheon he found a druggist, who gave him some laudanum, with directions how to take it. DeQuincey stated in the *Confessions* that in all his wanderings about London he was never able to find the same druggist again. In an hour there was marvelous relief from the pain, and later a stage of both mental and physical stimulation became apparent. After a time, DeQuincey was accustomed to call for a glass of laudanum negus, warm, without sugar" every day. He took laudanum eight years continuously. We are told that from his own account he arose to the astonishing amount of 8000 drops of laudanum, or about 7 wine glasses. After a time he was able to reduce to 1000 drops a day.

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on March 27. Dr. C. Guy Lane presided.

The first case presented was that of a forty-seven-year-old Swedish woman, who entered complaining of pain and a lump in the left axilla of two months' duration. Three months before entry a small skin lesion had developed on the left index finger. This had been followed a week later by lymphangitis, and a month before entry, red, tender papules came out on both forearms. These continued to appear, and each lesion lasted about three weeks. Coincidentally a lump appeared in the left axilla. Five days before entry, burning of both eyes with photophobia was noticed. Physical examination showed injection of the conjunctivae and considerable lacrimation. There was a lemon-sized, soft, slightly tender mass in the left axilla, which was fixed to the skin. Ten to fifteen, round, erythematous purplish papules were seen on both forearms, chiefly on the dorsal aspect. The routine laboratory examinations were negative except that a blood Hinton test was positive. The case was presented as an example of erythema multiforme.

The second case was that of a seventeen-year-old salesgirl, who had presented ulcers on the lower legs for the past four years. These recurred each winter after the first snow and always healed in the summer, leaving round pigmented areas. The physical examination was negative except for punched-out ulcers about 1 cm. in diameter. There was some surrounding induration and a diffuse brownish red pigmentation of the legs and scars of previous ulcers. The laboratory work was negative. The skin temperature readings were considerably increased during spinal anesthesia. Normally her feet were very cold. Dr. John Homans discussed this patient and considered her as a probable example of erythema induratum. He has treated such cases by sympathectomy, with good results. The question arose as to whether the temperature of the lower extremities would be permanently elevated by such measures. Dr. Homans reported that the ulcers always healed after this procedure. Dr. Lane discussed the important features of erythema induratum.

Dr. Edward A. Edwards spoke on "The Pigments and Color of Living Human Skin." Not only is the normal eye incapable of accurate color judgment, but in addition, 4 per cent of the population are color blind, and 30 per cent subaverage in their response to color. In many diseases it is desirable to have an objective record of the skin color. The data for this specification can be obtained instrumentally by the Hardy recording spectrophotometer. This instrument measures the reflection of light at each wave length of the visible spectrum. Not only does the curve obtained give bases for color specification, but also, by observing the absorption bands present, one can identify the factors responsible for skin color.

Five pigments and one additional optical effect were found to give skin its color. The pigments are melanin, melanoid (a derivative of melanin), oxyhemoglobin, reduced hemoglobin, and carotene. The turbidity of the deeper portions of the epidermis adds a blue component to the reflected light through the optical process called scattering. These factors were studied in the curves obtained from normal adult subjects in the hope that this would form a basis for future work in disease.

Melanin is present in granules in the deep layers of the

in brunettes, and present in large amounts only in the skin of dark races. Melanin was extracted from the skin of a Negro and transmission curves were made of this substance in varying concentration. As the concentration varies, the color changes from a brown to a yellow, and finally to an orange red. This corresponds to color changes seen in the various races. Except for melanin formation, which is induced by exposure to sunlight, it follows a very definite pattern, which was shown in chart form. It is richest in the skin of the scrotum and areolae mammae, fairly rich in that of the axilla and perineum, and only slight in amount in that of the palms, soles, breasts and buttocks. It is low in the skin of the trunk, increasing dorsally from the scapular to the lumbar regions.

Melanin can also be responsible for a blue color when it is heavily massed beneath the epidermis. This is seen in the 'sacral patch' of Oriental children and also in the shaven cheek of the adult white male.

Melanoid appears to be a degradation product of melanin, resembling it somewhat but having an absorption band in the visible violet. Its effect is especially noticeable in the skin of the soles of the foot, where the stratum corneum of the epidermis is heaviest.

Transmission curves were shown of reduced and oxyhemoglobin and their differentiating absorption bands pointed out. In the spectrophotometric curves strong evidence of oxyhemoglobin pointed to a rich arterial supply or a fast rate of blood flow, while marked evidence of reduced hemoglobin pointed to the presence of large veins or a sluggish blood supply. Arterial blood is most prominent in the skin of the palms, soles, head and neck, and over the ischial tuberosities. Venous blood predominates in the skin of the lower trunk and scrotum and on the dorsa of the feet.

Carotene was shown to influence skin color. It was proved to be located in the subcutaneous fat, as well as in the stratum corneum of the epidermis. Its distribution in the skin resembles that of arterial blood.

The scattering of the deeper, turbid layers of the epidermis varies according to the thickness of these layers. However, it is hard to map out the regional variations in scattering because wherever the epidermis is heavy the melanoid is likewise increased and raising of the blue end of the spectrum by scattering is offset by the absorption of melanoid. Conversely, of course, it is difficult to determine the distribution of melanoid.

Women have less evidence of melanin and blood in their skins, but show much greater evidence of carotene than do men. Carotene is particularly plentiful in the skin of the abdomen, breasts and buttocks—regions that contain but little in men.

The characteristic color of the dark subjects studied (Hindu, Japanese, mulatto and Negro) seemed to be due entirely to the amount of melanin present. They showed no differences in the amount or distribution of the other normal pigments, or evidence of any pigments not found in Whites.

BOSTON CITY HOSPITAL
ALUMNI ASSOCIATION

A meeting of the Boston City Hospital Alumni Association was held in the amphitheater of the Dowling Surgical Building, Boston City Hospital, on April 23. Dr. Soma Weiss presided. Six papers were presented, all dealing with subjects related to disease of the lungs.

The first paper was presented by Dr. Maxwell Finland, on "Pneumonia with Especial Reference to Treatment." Dr. Finland traced the history of the pneumonia service of the Boston City Hospital from its original in-

the present time. He pointed out that the mortality rate for all the treatable types has dropped to encouragingly low levels. He discussed the increasingly complex nature of the various branches of the pneumonia service, and pointed out the pressing need at the present time for further facilities for diagnosis, treatment and investigative study.

The second paper was presented by Dr Theodore L. Badger, entitled "The Significance of the Negative Tuberculin Reaction in Young Adults." Dr Badger discussed the results of a study on a series of tuberculin tested nurses at the Boston City Hospital, among whom 57 per cent were found to be tuberculin positive. In the entire group, 8 cases of pulmonary tuberculosis developed. Only 1 of these occurred in the tuberculin positive group, the other 7 cases were in nurses who had been tuberculin negative at the onset of their training. The ages were between eighteen and twenty three years. Several types of onset were encountered, among which were (1) primary type with enlarged hilar nodes and mid lung parenchymal involvement, (2) single apical lesions, and (3) long-continued fever with small parenchymal lesions, followed by pneumonic tuberculosis in one apex. All these cases were found following the appearance of a positive tuberculin reaction. Other investigators, including Heinbeck, Amberson and Myers, have noted the greater susceptibility to tuberculosis in negative reactors.

The third paper was read by Dr John A. Foley, who presented the case of a seventeen year-old girl who entered the hospital complaining of multiple joint pains for five weeks. Following entry, she developed a diffuse erythematous rash, ran a constantly elevated temperature, and exhibited a generalized lymphadenopathy. Subsequently she developed effusions in both pleural cavities. A diagnosis of disseminated lupus erythematosus was considered as a possibility. Biopsy of a lymph node proved negative for tuberculosis histologically, but subsequently a guinea pig inoculation with lymph node material was found to be positive.

The fourth paper was presented by Dr Francis W. Palfrey, whose subject was "Locating an Empyema." Dr Palfrey outlined the various physical signs which may determine the location of empyema. He pointed out that a suspicion of empyema may be based on a variety of clinical symptoms, which may include a continuation of post pneumonic fever with leukocytosis, or may only consist of apathy and anorexia. Empyema may occur over the site of previous consolidation, may have gravitated to the base of the pleural space, may be interlobar, or may be in the region of the vertebral bodies, pericardium or mediastinum. In percussion, the tactile sense with the forefinger as pleximeter is more acute than with the second finger. The signs of empyema are variable. They may in some cases be the same as the signs of the previous consolidation, with increased breath sounds and bronchophony, instead of the classic signs of fluid. Tactile fremitus, if elicitable, is a valuable differentiating sign. Interlobar empyemas may be located in back in the inter scapular region, or in front along a diagonal line between the upper axilla and the lower sternum. Basal empyemas may be evidenced only by a slight upward bulge in the lower midaxilla. Mediastinal empyemas may be determined by percussion over the vertebral bodies. Inaccessible empyemas may be located under the scapula or overlying the vertebral bodies. Anterior midline empyemas may be aspirated by a puncture close to the right lower cardiac border.

The x-ray diagnosis of empyema may be extremely difficult. The dome of the diaphragm may obscure a low

collection of pus posteriorly. Also, the x-ray may simply show an extensive opaque area in which empyema cannot be distinguished from underlying lung disease. The lateral view is often valuable for localization.

The fifth paper was read by Dr Louis M. Freedman, on the subject "The Etiology of Lung Abscesses." Dr Freedman pointed out the growing popular interest in lung abscesses following tonsillectomies, and presented the results of a study to determine the relative frequency of the various causes of lung abscesses. The investigation covered all the lung abscesses at the Boston City Hospital over a ten year period.

The study revealed that of the abscesses occurring post-operatively, the largest number followed tonsillectomy. However, the number of tonsillectomies far exceeded all other types of operation performed, and actually the incidence of abscesses following tonsillectomy was lower than that for other operations. In this group, the ratio of incidence of abscesses to operation was 1:1654, in children, the ratio was 1:8852, and in adults, 1:626. The lowest incidence occurred following local anesthesia.

It was concluded that the chief factors in the incidence of postoperative abscesses were the presence of infection in the upper or lower respiratory tract, the type of anesthesia, the prolonged retention of aspirated material, the development of atelectasis, an infective source, and limitation of pulmonary ventilation. The question of whether abscesses arise from aspiration or embolism remains unanswered, but evidence seems to favor the former as the chief cause. The location of most postoperative abscesses was found to be in the right lower lobe, near the proximal portions of the bronchial tubes. Satisfactory experimental abscesses have not been produced in animals by either mechanism.

Medical conditions leading to abscess formation far exceeded in number the postoperative abscesses. Pneumonia, influenza, chronic suppurative conditions, tumors and atelectasis from any cause were the chief conditions encountered.

It was concluded that tonsillectomy is considered to be a prominent cause of lung abscess only because it is the most frequently performed operation, it actually carries no higher an incidence of abscess.

The sixth paper was presented by Dr John W. Strieder, on the subject "Certain Aspects of Pulmonary Surgery." Dr Strieder briefly traced the history of thoracic surgery during the past fifty years and summarized certain of the more recent advances that have been made. In bronchiectasis, surgery is now recognized as an established form of therapy. The present mortality for lobectomy is approximately 8 per cent. In bronchiogenic carcinoma, surgery offers the only hope for recovery at present. X-ray therapy has not been definitely proved to have brought about any five-year cures in cases where a histological diagnosis has been made. The diagnosis of carcinoma is suggested by the symptoms of cough, pain and hemoptysis. The x-ray diagnosis is based on the finding of an area of atelectasis resulting from bronchial occlusion. Bronchoscopy is extremely valuable in securing tissue for microscopic diagnosis. Diagnostic pneumothorax is sometimes valuable, particularly when combined with thoracoscopy. Exploratory thoracotomy is of questionable value. Total pneumonectomy in the treatment of carcinoma was first performed by Dr Ewart Graham with a five year cure. The operative mortality for this procedure, however, is still extremely high.

Progress in cardiac surgery is best represented by the recent revascularizing operations devised by Beck and by

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital on March 27. Dr. C. Guy Lane presided.

The first case presented was that of a forty-seven year-old Swedish woman, who entered complaining of pain and a lump in the left axilla of two months duration. The investigation covered all the lung abscesses at the Boston City Hospital over a ten year period.

The study revealed that of the abscesses occurring post-operatively, the largest number followed tonsillectomy. However, the number of tonsillectomies far exceeded all other types of operation performed, and actually the incidence of abscesses following tonsillectomy was lower than that for other operations. In this group, the ratio of incidence of abscesses to operation was 1:1654, in children, the ratio was 1:8852, and in adults, 1:626. The lowest incidence occurred following local anesthesia.

It was concluded that the chief factors in the incidence of postoperative abscesses were the presence of infection in the upper or lower respiratory tract, the type of anesthesia, the prolonged retention of aspirated material, the development of atelectasis, an infective source, and limitation of pulmonary ventilation. The question of whether abscesses arise from aspiration or embolism remains unanswered, but evidence seems to favor the former as the chief cause. The location of most post-operative abscesses was found to be in the right lower lobe, near the proximal portions of the bronchial tubes. Satisfactory experimental abscesses have not been produced in animals by either mechanism.

Medical conditions leading to abscess formation far exceeded in number the postoperative abscesses. Pneumonia, influenza, chronic suppurative conditions, tumors and atelectasis from any cause were the chief conditions encountered.

It was concluded that tonsillectomy is considered to be a prominent cause of lung abscess only because it is the most frequently performed operation, it actually carries no higher an incidence of abscess.

The sixth paper was presented by Dr John W. Strieder, on the subject "Certain Aspects of Pulmonary Surgery." Dr Strieder briefly traced the history of thoracic surgery during the past fifty years and summarized certain of the more recent advances that have been made. In bronchiectasis, surgery is now recognized as an established form of therapy. The present mortality for lobectomy is approximately 8 per cent. In bronchiogenic carcinoma, surgery offers the only hope for recovery at present. X-ray therapy has not been definitely proved to have brought about any five year cures in cases where a histological diagnosis has been made. The diagnosis of carcinoma is suggested by the symptoms of cough, pain and hemoptysis. The x-ray diagnosis is based on the finding of an area of atelectasis resulting from bronchial occlusion. Bronchoscopy is extremely valuable in securing tissue for microscopical diagnosis. Diagnostic pneumothorax is sometimes valuable, particularly when combined with thoracoscopy. Exploratory thoracotomy is of questionable value. Total pneumonectomy in the treatment of carcinoma was first performed by Dr Ewart Graham, with a five year cure. The operative mortality for this procedure, however, is still extremely high.

Progress in cardiac surgery is best represented by the recent revascularizing operations devised by Beck and by

O'Shaughnessy, which open up a promising field in the treatment of cardiac disease.

The esophagus has been termed the "last frontier of surgery." Several new operative methods of treating carcinoma of the esophagus have been devised which may eventually prove to be successful.

Dr Strieder presented a series of lantern slides to demonstrate operative procedures for a variety of chest diseases, including carcinoma, bronchiectasis and tuberculosis. He then exhibited a case of a young man who had entered the hospital with cardiac tamponade resulting from a stab wound, he was immediately relieved by a pericardial tap and the removal of blood. No operation was found necessary, and bleeding has not recurred.

The papers were discussed by Dr Horace Binney, who also presented a summary of progress in the operative treatment of tuberculosis at the Boston Sanatorium. Thoracoplasty has proved to be of increasing value, both in arresting the disease and in preventing new infections by the closure of cavities. Since its introduction the total mortality from tuberculosis has appreciably dropped.

GREATER BOSTON MEDICAL SOCIETY

The Greater Boston Medical Society met Tuesday evening, April 5, at the auditorium of the Beth Israel Hospital, in Boston. The speaker was Dr Louis Nahum, assistant professor of medicine, the Yale University School of Medicine. His subject was "Comments on the Coronary Arteries from the Clinical Standpoint, with Special Reference to Prognosis." Dr Louis M. Freedman, of Boston, presided.

The myocardium is considerably more sensitive to lack of oxygen than skeletal muscle. This fact is brought out by the observations of Katz and Long. They found that the heart will go into rigor when it has accumulated 70 mg per cent of lactic acid. This is about one quarter of the quantity necessary to initiate rigor in skeletal muscle.

There are two mechanisms for increasing the oxygen supply to the heart muscle: (1) vasodilatation from increased cardiac activity and (2) greater vascularity of myocardial fibers. The first fact is not generally recognized. The second is borne out by the observation that each myocardial fiber is supplied by two capillaries, while each skeletal muscle fiber is supplied by only one.

The maximum blood supply which a heart can receive is about three times normal, that is, up to 700 cc. per minute. If coronary-artery disease is present there may be a great discrepancy between work and blood supply.

The heart has two venous systems. One is the gross system, including the coronary sinus and other larger veins. The other consists of the Thebesian vessels. The two systems facilitate a greater blood flow through the system.

In the arterial system there are two sets of collaterals—the extrinsic and intrinsic. The former plays a very small part normally. It is derived from the aorta and the bronchial, pericardial and internal mammary arteries. The intrinsic collaterals are of greater importance and consist of (1) anastomoses between the right and circumflex branches of the left coronary arteries, (2) terminal anastomoses of arteries, (3) small vessels in epicardial fat which connect one part of a coronary artery with another part, and (4) Winternitz's intimal sinusoids, which may become of extraordinary significance. Perhaps these vessels carry adequate blood supply in cases of complete coronary occlusion, as in the cases of Leary and Wearn.

In studying cases with coronary artery disease one finds a variety of clinical pictures. This is not entirely depend-

ent on the degree of involvement, for there are cases with marked lesions and a minimum of symptoms. The reverse is likewise true. The factors responsible for the diversity of clinical pictures are (1) the state of the collateral channels, (2) the rate of progression of the arterial disease, and (3) the appearance of an accident, that is, closure.

Dr Nahum summarized the present ideas of Dr Winternitz relating to the cause and progression of arteriosclerosis. With the technic of arterial clearing Dr Winternitz showed hemorrhages in the intimas of normal arteries. This is interpreted as being due to a rupture of intimal sinusoids. The hemorrhage may be so slight as to cause no change or it may be extensive and raise the intima from a slight degree to the point of complete closure. The liberated lipid from the hemorrhage becomes calcified.

At times the intimal hemorrhage will rupture into the lumen. The resulting raw intimal surface predisposes to the development of thrombosis. The initiation of thrombosis is not necessarily followed by complete closure of the vessel lumen. Indeed, it may take as long as two weeks for complete closure.

Predisposing factors to the development of arteriosclerosis were next considered. They are as follows: (1) sex—in Dr Nahum's series of patients with coronary artery disease only 25 per cent were women, (2) diabetes—almost all cases of uncontrolled diabetes for a period of five years have generalized arteriosclerosis, (3) body weight—this seems to be an important factor, for coronary-artery disease is two and a half times more common in people who are overweight than in those who are not, and (4) hypertension—nearly everyone who has had hypertension for any length of time has arteriosclerosis.

About 40 per cent of the patients with clinical coronary artery disease are likely to develop clinical infarction following thrombosis. Thrombosis is an accident and is generally unpredictable. In an attempt to forestall thrombosis one can advise increased rest and loss of weight. Some believe this helps. Drugs seem to be rather discouraging in this respect. Activity within comfort does not seem to increase the tendency to the development of thrombosis. It would seem that overexertion can be responsible for development of this accident. Several cases were cited in which overexertion seemed to have played a positive role. If overexertion is to be blamed for an attack of coronary thrombosis, there must be exertion beyond ordinary capacity and a reasonable interval between the effort and the thrombosis.

There are several clinical factors which may be used in attempting to estimate the size of a myocardial infarct. It is usually in inverse proportion to the efficiency of the heart. Thus one would expect a small infarct if the pulse is good, the respirations not altered, and the lungs without congestion. Slight or absent fever and no appreciable fall in blood pressure are likewise good signs. The reverse, however, indicates a larger infarct and a consequent, graver prognosis.

Since the length of induced invalidism should depend on the size of the infarct it is important to be able to judge the latter. Having determined this fact one can attempt to determine the length of time needed for the infarct to heal. The smaller infarcts are probably healed in three weeks, the larger ones may take as long as three months.

Factors other than size which influence the time of healing are anemia and avitaminosis. One should attempt to correct or prevent these conditions in every case of

coronary thrombosis with myocardial infarction. It is doubtful whether any drug at one's disposal influences the healing of infarcts. The theobromine group seems to be of no help. Dr Nahum has abandoned the use of intravenous glucose. Morphine should be used, as necessary, to abolish pain. Early recognition of the condition and prompt immobilization of the patient are two measures preventing fatalities. Rest should consist of mental and physical quiet, the diet should be reduced, for cardiac output increases with large meals.

In myocardial infarction the electrocardiogram is frequently a specific diagnostic procedure, much as the x ray is in fractures or tuberculosis.

The discussion was carried on by Drs Ayman, Schlesinger, Morrison, Blumgart and Riseman. It was brought out that in cases of myocardial infarction it is common to find more than one vessel occluded. Presence or absence of infarction depends more on the rate of occlusion than the size or number of vessels occluded. A factor which tends to initiate coronary thrombosis is lowered blood pressure. Examples are cases occurring during spinal anesthesia and following severe hemorrhage from peptic ulcer.

In closing the discussion Dr Nahum brought out the fact that survival depends on the size of the infarct rather than the age of the patient. Development of collateral circulation depends not on age but on the presence of arteriosclerosis. The ultimate outcome depends on which of these factors develops faster.

NOTICES

MEDICAL LIBRARY ASSOCIATION

The fortieth annual meeting of the Medical Library Association will be held at the Hotel Somerset, Boston, June 28 to 30. Sessions will be held at the Boston Medical Library and Harvard Medical School, with open house in the libraries of the city.

The speakers will be Dr Henry R. Viets, of Boston, Dr Sanford V. Larkey, of Baltimore, Dr John F. Fulton, of New Haven, Connecticut, and Mrs Eileen R. Cunningham, Miss Isabelle T. Anderson, Mr James F. Ballard and Mr Herman H. Henkle.

Symposiums on a Guide to Medical Literature and Medical Literature of the Past will also be featured.

CAMBRIDGE HOSPITAL

The regular clinicopathological meeting of the staff of the Cambridge Hospital will be held at the hospital, 330 Mt. Auburn Street, Cambridge, Tuesday, June 21, at 8 p. m.

All members of the medical profession are cordially invited to attend.

JOSEPH M. WADDEN, M.D., *Secretary*

CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in the Andrew Carney Assembly Room on Monday morning, June 20, at 11 30.

There will be medical, surgical, gynecological, obstetrical and urological case reports.

Physicians and medical students are cordially invited.

R. J. HEFFERNAN, M.D., *Secretary*

BOOK REVIEWS

Handbook on Social Hygiene Edited by W. Bayard Long and Jacob A. Goldberg. 422 pp. Philadelphia: Lea & Febiger, 1938. \$4.00

This handbook is a very complete, well planned and well written contribution concerning some of the problems of social hygiene. The first half takes up in some detail the treatment of syphilis and gonorrhea. The treatment of syphilis is considered under various headings, such as syphilis of the nervous system, and prenatal and congenital syphilis. There are chapters on gonorrhea in the male, gonorrhea in the female, and vaginitis. One chapter is devoted to laboratory aspects of these diseases.

The second half of the book is concerned with the social aspects of gonorrhea and syphilis. There is an excellent chapter by Dr. Munger on hospitals and outpatient clinics. In this chapter, the contributor condemns the policy followed by many hospitals of refusing to admit patients with these diseases.

The public-health point of view is presented by Dr. Clarke, who makes the statement that all cases with infectious syphilis should be hospitalized until they become non-infectious.

An interesting chapter is one by Dr. Goldberg on statistics relating to syphilis and gonorrhea. Other chapters deal with social service, the responsibility of nursing schools, the public health nurse and syphilis control, and the prob-

lems of syphilis and gonorrhea in family welfare agencies. The ideals of the social hygiene societies are well stated in a chapter by Dr. Bigelow, and another chapter gives the legal aspects of the venereal diseases, including a section on marriage laws.

From the preceding outline, it will be seen that the subject is covered from many angles—medical, social and legal. The handbook is a valuable book for reference and will serve well as a textbook for students.

Scientific Contributions in Honor of Joseph Hersey Pratt on His Sixty-Fifth Birthday. Anniversary Volume. By his friends. 983 pp. Lancaster: Lancaster Press, Inc., 1937. \$7.00.

Those of us who admire Dr. Joseph H. Pratt will like this book, and if it is true that a man can be judged by his friends, even the most critical will agree that Dr. Pratt has achieved much honor in the medical profession, for his friends, as the book testifies, are scattered so eminently all over the world.

The most outstanding feature of the volume is its list of contributors. This consists of a group of one hundred twelve writers beginning with Joseph C. Aub and jogging on comfortably through the alphabet to Robert W. Wilkins. Almost every name well known to modern medicine appears, and, of course, old friends of Dr. Pratt's like Richard Cabot, Henry Christian, Frank Fulton, Louis Hamman, Elliott Joslin, Samuel Lambert, Warfield Longcope, David Riesman and Walter Steiner—to mention a few—have written articles for it.

All the pages that make up the book are friendly, well printed and happily edited. The topics discussed cover almost every phase of medical thought from "The Minneapolis Giant" to "The Effect of Vitamin C on the Culture of H37 Tubercle Bacillus" or from "Metabolic Studies in a Man Who Lived for Years on a Minimum Protein Diet" to "Marcus Whitman and Narcissa Prentiss—A Study of Romance, Adventure, Achievement and Tragedy." The charm of it all lies in the delightful manner in which so many of Dr. Pratt's friends have written something in honor of his sixty-fifth birthday, not because they were asked to but for the joy of paying him a nice compliment.

Thus the book is unusually attractive. It colors and adds background to Dr. Pratt's photograph which appears as a frontispiece, to the list of his own published works, to the short biographical sketch of him that opens the book, and to the description of the New England Medical Center that ends it. No better characterization of a man's knack at making and holding friends could be devised than this volume. A doctor so gifted in the art of friendship must indeed be a great physician. It is pleasant to have on record such a significant portrait.

An Introduction to Dermatology. Richard L. Sutton and Richard L. Sutton, Jr. 666 pp. Third edition. St. Louis: The C. V. Mosby Company, 1937. \$5.00.

The third edition of the 'small Sutton has been improved considerably. Much new material and numerous new illustrations have been added. A number of skin conditions to which new names have been attached are covered in this third edition. Syphilis has been given more consideration with the work of the Co-operative Clinic Group included, and more attention paid to treatment. Treatment in general has been amplified. The arrangement of the book has been improved by the attempt to follow more closely a classification on etiology. On the whole the book provides, in a relatively small space,

abundant information about cutaneous disease for the student and general practitioner. The illustrations are excellent, with a few exceptions, and clearly show conditions which much description would fail to describe satisfactorily to the reader.

The Endocrines in Obstetrics and Gynecology. Raphael Kurzrok. 488 pp. Baltimore: The Williams & Wilkins Company, 1937. \$7.50.

In less than 500 shiny pages printed in large easily readable type, Kurzrok has successfully attempted to present the current theories and facts, as well as some of the fancies, of the endocrines in their relation to general medicine. Just enough of the historical and anatomical background is given to afford a take-off.

The prodigious mass of literature on experimental biology of the sex-endocrines is expertly sifted and only that pertinent to rational diagnosis and organotherapy included. Into chemistry, however, the author takes the clinical reader way over his head where he finds himself among intricate benzene rings which even with many double bonds do not serve as lifesavers. Yet the passages must not and need not be avoided, for floating through them are the *ones*, *ols* and *ins* as well as the *APLH's*, the *FSH's* and the *LH's*, that are the logs out of which the reader is enabled with surprisingly little effort to build a resounding raft which may save his therapeutic life.

The ill understood but well recognized influence of the thyroid and the adrenal glands on reproductive processes receives moderate and conservative attention, as do also some of the current notions about the pancreas, the thymus and the parathyroid glands. Menstruation, in order and disorder, and ovulation, too, are considered in such detail that any experienced reader may find much with which to disagree. On this, as on other subjects, and especially on chemistry, the author freely (and properly so) presents his own theories and a great deal of his own original work, with which there is not complete agreement from other workers in the field. This need cause no confusion, however, for the text abounds in tact and modesty, and when no one knows the answer to a problem, intelligent and informal discussion is the best substitute for the missing solution. This very instructive book will answer, at least temporarily, the prayer of the clinician distressed by the rapid growth of sex-endocrinology and the insistent demand for organotherapy.

Psychiatric Nursing. William S. Sadler, in collaboration with Lena K. Sadler and Anna B. Kellogg. 433 pp. St. Louis: The C. V. Mosby Company, 1937. \$2.75.

This book has much valuable information in it. It attempts to cover too much ground, however. The author inadequately presents historical developments in psychiatry, a bit of neuroanatomy, an inadequate picture of mental disease including some references to the etiology, prognosis, and treatment, a bit of occupational therapy, and mentions helio- and hydrotherapy with pictures of their application.

The author would have done better to have confined himself to subjects more germane to psychiatric nursing. Trying to carry water on so many shoulders at once has resulted in unnecessary spilling. Had the author confined himself to the technics essential for a well trained nurse to add to her armamentarium to qualify as a psychiatric nurse for mental cases the book would have been more readable and valuable.

NUMBER 25

TREATMENT OF PNEUMOCOCCIC MENINGITIS

A Study of Ten Cases Treated With Sulfanilamide Alone or in Various Combinations With Specific Antipneumococcic Serum and Complement, Including Six Recoveries

MAYWELL FINLAND, M.D.,* JOHN W. BROWN, M.D.,† AND
ALBERT E. RAUH, M.D.‡

BOSTON

WE have had the opportunity, during the past few months, to study intensively a number of cases of pneumococcic meningitis treated with sulfanilamide alone or in various combinations with specific antipneumococcic serum and fresh human serum (complement). In this paper we are presenting a group of cases illustrating certain aspects of these studies. The immediate interest in these cases concerns 6 patients who recovered. The method of treatment tentatively evolved and the one which thus far has given the most favorable results as judged by the clinical response and the laboratory findings in this small group of cases will be described. This method is based upon the results of clinical, bacteriological and immunological studies in patients with pneumonia and other pneumococcic infections, including meningitis, and upon more recent investigations of the mechanism of the action of sulfanilamide, alone or in combination with specific serum, on pneumococci in human blood (in vitro) and in patients undergoing treatment for pneumococcic infections. The details of these studies are left for separate consideration elsewhere. It will suffice to enumerate here the pertinent findings which provided the rationale for the present approach.

It may be stated at the outset that a number of studies in some of the present cases have not yet been completed. Moreover, it is felt that

further observations, in a larger number of cases, are necessary before final conclusions can be drawn with regard to the principles involved, and the relative importance of each of the various steps and agents used in the treatment. It will also be essential to assess the quantitative aspects of the treatment, the various types of cases in which this method of therapy is applicable and effective, and the importance of other therapeutic measures. At this time no attempt will be made to review the numerous papers on pneumococcic meningitis that have appeared in the recent literature. These are concerned chiefly with clinical reports of isolated cases recovering either spontaneously or after various surgical measures, after specific therapy or, more recently, after treatment with sulfanilamide ‡

RÉSUMÉ OF BACTERIOLOGICAL AND IMMUNOLOGICAL FINDINGS IN CASES OF PNEUMOCOCCIC MENINGITIS

The clinical and bacteriological data have been accumulated in the course of several years' study of pneumonia and pneumococcic infection at the Boston City Hospital. The distribution of specific types in 99 cases of pneumococcic meningitis occurring at this hospital between November, 1929, and June, 1936, has been reported elsewhere.¹ There was no striking predominance of any types among these cases with the exception of the high frequency of Type III in cases complicating middle-ear and mastoid infections. None of these or of the subsequent cases recovered except the 6 to be described.

The numbers of pneumococci recovered from the cerebrospinal fluid in untreated cases of pneumococcic meningitis have usually been large and have frequently reached the numbers found in

†The exhaustive review by Holman, W. L., and Duff, G. L. (Am. J. M. Sc. 1935;39:416, 1935), contains references to most of the recent papers dealing with sulfanilamide in pneumococcic infections.

pure cultures of these organisms when grown in the most favorable fluid medium (from 1 to 1000 million living pneumococci per cubic centimeter of spinal fluid). Along with these organisms there is found a considerable amount of specific precipitable substance.

Two groups of immunological studies have been conducted. One concerned antipneumococcic immunity, natural and acquired. Many of these studies have been conducted along the lines indicated by the work of Ward² and Robertson³ and their respective co-workers whose findings were confirmed and extended. It was found that, for the destruction of pneumococci, three components are essential: specific antibodies, an adequate number of living phagocytic leukocytes, and a heat-labile factor (complement) residing in the serum. Except in infancy, most human beings have what might be called "natural antibodies" in that their blood is capable of destroying large numbers of many types of virulent pneumococci. These natural antibodies, however, are not associated with demonstrable type-specific agglutinins or with antibodies capable of protecting mice against otherwise fatal doses of pneumococci. The latter have been demonstrated only after immunizing contact with living pneumococci or with their antigenic components, that is, after infection, active immunization or the carrier state. These acquired antibodies seem to play an essential role in the mechanism of recovery from pneumococcic infections.

The second group of studies concerned patients with meningitis and were, for the most part, an application of the results of the investigations on pneumococcic immunity to studies similar to those on influenzal meningitis made by Ward and Fothergill.⁴ Only the salient findings need be mentioned.

We have not succeeded in demonstrating the presence of complement in the cerebrospinal fluid (0.4 cc was the largest amount of fluid used) from untreated cases of pneumococcic meningitis, with one exception. In this case, with infection due to Type VII pneumococcus, the first observation was made on cerebrospinal fluid obtained after the patient had received antimeningococcic serum intraspinally. Both the blood and spinal fluid had unusually high titers of specific Type VII antibody (mouse protection and agglutinins) at the time of this observation. This patient died several weeks later after multiple operations for brain abscesses. When fresh human serum was introduced intraspinally in active cases, the complement could not be demonstrated after the lapse of a few hours.

Patients with pneumococcic meningitis, like those with other focal pneumococcic infections, frequent-

ly have demonstrable specific antibodies (opsonins, agglutinins and mouse protection) for the homologous type in their circulating blood, provided there is no bacteremia. In meningitis associated with vegetative endocarditis, however, bacteremia and high titers of circulating homologous type-specific antibodies may coexist. No such antibodies can be demonstrated in the cerebrospinal fluid at the same time, except under unusual circumstances such as in the case just mentioned.

We have not been able to demonstrate pneumococcus antibodies (agglutinins or mouse protection) in the cerebrospinal fluid after the intravenous injection of antipneumococcic horse or rabbit serum, either in the presence or absence of meningitis.

Studies on the action of sulfanilamide have shown that, when this drug is added to whole defibrinated human blood in appropriate amounts, it has a moderate to marked bacteriostatic action on most of the strains and types of pneumococci tested. This action fails or is only slight in the blood of certain patients with pneumococcic infections, particularly if the blood stream is heavily invaded. Similar amounts of sulfanilamide markedly enhance the pneumococcidal action of immune serum (horse and rabbit) added to whole blood in vitro, even when the blood of a heavily invaded patient is used. The bacteriostatic and bactericidal action of the whole blood of patients with pneumococcic infections after receiving treatment with sulfanilamide or with this drug and immune serum is identical with that of the blood taken before treatment and tested after the addition of equivalent amounts of these materials in vitro.

In cases of pneumococcic meningitis the bacteriostatic action of sulfanilamide is evidenced by a rapid reduction in the number of organisms that can be cultured from the cerebrospinal fluid and apparent cessation of multiplication, at least for a considerable period after treatment is begun. With the reduction in the numbers of organisms there is a rapid rise in the sugar content of the cerebrospinal fluid, even while the infection persists and sometimes even in the presence of large numbers of organisms. If frequent punctures are done, the protein content of the fluid and the number of leukocytes may also drop markedly while the infection is still present. In some cases the infection clears up with this treatment alone after a varying length of time, usually ten days or more. It is possible that with proper doses this result can be attained more regularly and with many strains of pneumococci, but in most of the cases of our series, in which ordinary dosages were employed, the infection persisted and eventually increased.

again. These aspects and others are brought out more effectively in the case reports.

Certain other inferences and assumptions have been invoked in working out a rational method of therapy. These are based, in part, on the results of test-tube experiments and on what might be called "clinical impressions" from observations of the consequences of certain modes of therapy used in the past.

It may be assumed that, if any considerable quantity of a highly potent specific therapeutic serum is introduced into the spinal canal in an otherwise untreated case of pneumococcic meningitis, certain reactions may take place which are similar to those observed when such a serum is added to a test tube containing a heavily grown culture. These reactions would consist of agglutination of the organisms into large floccular clumps and the formation of a heavy precipitate from the interaction of the free soluble specific substance and its specific antibody. Such reactions may be harmful fully apart from their purely mechanical effect, since they would obviously enhance the possibilities of interfering with proper circulation and drainage of spinal fluid, and possibly enhance the inflammatory reaction in the meninges. *In vitro* phagocytic and pneumococidal tests on whole blood have shown that such agglutination and precipitation result quite regularly in the formation of large clumps of phagocytic leukocytes which become enmeshed in the clumps of agglutinated organisms, these cells become easily disrupted after they have engulfed numerous bacteria or they are prevented from acting on the bacteria. Free growth of organisms usually occurs under such conditions, whereas, if similar amounts of culture and much smaller amounts of serum are used, phagocytosis and killing of the pneumococci result. This has already been pointed out by Ward.² It may be further assumed that the precipitate may be toxic to the phagocytic cells as shown by Cromwell and Centeno,⁵ thus interfering further with their action even if complement and an optimum amount of the antibody were introduced.

One of our aims has been to avoid harmful reactions. We have learned from experiences with the intravenous use of concentrated antipneumococcic horse serums and from our recent experiences with therapeutic rabbit serums, that untoward reactions, entirely apart from what might be called reactions of sensitiveness, may follow the administration of these agents. Any type of reaction may prove harmful and even serious, particularly in the hands of inexperienced individuals. Furthermore, any given preparation may be ad-

ministered with impunity to a large number of patients and yet give untoward reactions of considerable severity in some isolated recipient. When such a reaction occurs after intravenous injections, particularly if one is prepared for such a contingency, it can usually be overcome by appropriate treatment. However, in certain old and debilitated individuals, and in some patients otherwise in good general condition who have had a severe infection and "toxemia" for several days, these reactions may be followed by a rapid decline and may possibly hasten a fatal outcome. Such general reactions, and perhaps even local reactions, may occur after intraspinal injection. These reactions, either by themselves or coupled with the interaction of the antibody with the components of the cerebrospinal fluid previously noted, may account for some of the sudden deaths or for the rapid declines that have been known to occur after intraspinal and especially after intraventricular injections of antipneumococcic serums. Since the reactions from intravenous injections cannot be predicted, in a given case, we have felt that the direct use of therapeutic antiserums intraspinally, at least in the amounts usually employed, should not be the method of choice and other methods should be tried.

Many cases of pneumococcic meningitis have or soon develop bacteremia. Except in cases with endocarditis, to which reference has already been made, it would seem essential for the proper control of the meningitis to prevent or control the bacteremia. This may be accomplished in many instances by the use of appropriate doses of sulfanilamide. According to our observations, the efficacy of this agent is quite uncertain when it is employed alone, and we have definitely failed to control heavy blood-stream invasions in many pneumonia patients by the use of large doses of the drug. However, we have found that specific serum given intravenously, particularly if used in conjunction with sulfanilamide therapy, has effectively controlled even massive blood-stream invasions. It seems reasonable, therefore, that this procedure should be an important adjunct to the treatment of pneumococcic meningitis. Obviously, if it can be shown that the patient already has a large excess of circulating antibodies against the infecting organism in his blood stream, as demonstrated by the presence of agglutinins, precipitins or mouse-protective antibodies, the intravenous injection of therapeutic antibody would be superfluous. The demonstration of naturally occurring opsonins, as shown by phagocytosis or by pneumococidal action of the whole blood, is not usually sufficient, since these have been demon-

strated early in the course of pneumococcic infections even in the presence of progressive bacteremia^{3, 6}

It seems reasonable to suppose that, following the use of sulfanilamide, which, as we have noted, results in decreasing the infection in the meninges at least temporarily, small amounts of specific antibody and complement may, in some individuals, reach the infected meninges and not be detectable by the ordinary tests because they are rapidly used up. In this event recovery might take place without further treatment. On the other hand, although our studies in this direction have not yet been completed, it would appear from the data now available that after antipneumococcic horse or rabbit serums are given intravenously, even in the presence of only small numbers of pneumococci, the antibody does not reach the cerebrospinal fluid in demonstrable amounts. It would seem necessary, in most instances, to introduce some antibody into the infected area provided that this could be done without undue risk of severe reactions. After much of the cerebrospinal fluid present before the beginning of sulfanilamide therapy has been drained off by lumbar punctures and the infection reduced by the use of the drug, very small amounts of specific antibody should be sufficient to complete the sterilization of the cerebrospinal fluid provided that there have not yet developed any well-localized areas of abscess formation.

The most readily available supply of antibody which is the least likely to give untoward reactions and at the same time provide complement and an optimum amount of antibody, is the patient's own fresh serum after a balance of specific antibody has been established in the circulating blood.

PROCEDURE ADOPTED

For these reasons we have resorted to the following general procedure:

- 1 Complete and frequent drainage of the spinal fluid

- 2 Immediate institution and continuous use of large doses of sulfanilamide by mouth or by subcutaneous injection, if necessary. The optimum dose has not been determined. Sodium bicarbonate is given with each dose.

- 3 Identification of the pneumococcus as rapidly as possible and the intravenous administration of sufficient specific antipneumococcic serum, to establish a balance of antibody in the circulating blood.

- 4 Moderate fluid intake by whatever route necessary, to insure adequate amounts of spinal fluid for drainage.

- 5 About two hours after a reasonable dose has

been given, blood is withdrawn from the patient and serum rapidly separated.

- 6 Following the removal of spinal fluid at the time of the next lumbar puncture, this serum is given intraspinally (5 to 10 cc should be sufficient, the optimum amount has not been determined but it is probably small). This procedure may be repeated after subsequent lumbar punctures, if necessary. In small children or in infants it may be necessary to use fresh human serum from another source for complement, and, in that event, only very small amounts of specific therapeutic serum need be added (0.5 cc or less should be sufficient).

- 7 Lumbar punctures are repeated until the fluid is normal. The frequency is determined by the initial pressure of the fluid and its cellular and protein contents.

- 8 Transfusions are given after the first week of sulfanilamide therapy if anemia develops, and are repeated, as necessary, until the drug is discontinued (after 7 to 14 days of sterile fluids).

These procedures serve to insure a balance of antibody in the blood stream and to control the bacteremia. They should, in most instances where the sulfanilamide effectively reduces the infection, provide an adequate amount of antibody and complement in the optimum proportions and in a medium which is likely to give the least local or general reaction and the greatest antibacterial effect. The cases to be presented will illustrate the application of some of the principles enumerated.

RÉSUMÉ OF THE CASE HISTORIES AND LABORATORY STUDIES

The salient features of the clinical courses will be summarized in the text and in the legends to the figures. The essential details of the therapy and of the laboratory findings are shown graphically in the figures. For the sake of brevity only pertinent data which are not shown in the figures will be mentioned in the text.

Case 1 A 19 year-old, white, Italian schoolboy was admitted to the hospital May 23, 1937, delirious and irrational. From his sister it was learned that he had complained of headache, general malaise and fever for 2 days. On the morning of admission his headache and malaise increased. He became markedly prostrated and then delirious, and was taken to the hospital.

He had had measles, whooping cough and diphtheria in early childhood, and pneumonia at the age of six. Two years prior to entry he sustained a head injury with loss of consciousness for several hours. Following this injury he complained frequently of severe headaches and dizzy spells.

Examination at the time of admission showed a normally developed adolescent, acutely ill but co-operative.

in spite of a muttering delirium. His skin was warm and moist. The throat was dry and injected. There was moderate rigidity of the neck and bilateral positive Kernig sign. The optic disks were well outlined, and the vessels appeared normal. Other reflexes were active and equal on both sides. Subsequent examination by an aural surgeon revealed no abnormalities of the ears, nose or paranasal sinuses. Lumbar puncture revealed cloudy fluid under a pressure of 410 mm of water. Smear of the fluid showed suggestive diplococci which appeared to be decolorized with the Gram stain. Culture, however, showed Type XI pneumococcus.

The patient was immediately given 5 gm of sulfanil

Figure 1* Case 1 Primary (?) Type XI pneumococcus meningitis with bacteremia. Intensive and sustained treatment with sulfanilamide by mouth, subcutaneously and intraspinally. Complete control of bacteremia and temporary improvement in clinical condition and in spinal-fluid findings. Failure completely to control the meningeal infection. Development of antibodies in the circulating blood and failure to demonstrate these antibodies in the spinal fluid. Increase in bacterial counts of spinal fluid after intraspinal injections of fresh human serum from a non-immune donor during the presence of circulating antibodies in the blood. Progressive anemia partly improved by transfusion. Death after four weeks. Autopsy: purulent meningitis and cerebral (frontal lobe) abscess—Pneumococcus Type XI hemorrhagic bronchopneumonia—hemolytic *Staphylococcus aureus* and alpha hemolytic streptococci (no pneumococci).

amide by mouth and then daily amounts of this drug as indicated in the chart. These amounts were given in four divided doses at 6-hour intervals. Only one subcutaneous injection of 350 cc. of 0.8 per cent solution was given on May 1. On May 8 the drug was discontinued for the day because of increasing anemia. The total amount of the drug given was approximately 105 gm. by mouth, 3 gm subcutaneously, and 2.5 gm intrathecally. The fluid intake was maintained at 3000 to 4000 cc. daily, intravenous normal saline and 5 per cent glucose solutions being used when insufficient amounts were taken by mouth. On the second day in the hospital he seemed improved and became rational. On that day herpes labialis appeared, and his skin assumed a dusky cyanotic tinge. The carbon-dioxide combining power of his blood at this time was 35 vol per cent. Thereafter sodium bicarbonate was given with each dose of sulfanilamide in equal amounts. Intraspinally injections of 15 cc. of fresh human serum from a Group A donor (the patient's blood was Group A) were given on May 14 and 16. The fresh whole defibrinated blood of this donor showed phagocytosis and pneumococcal activity for the patient's organisms, but no agglutinins. These injections did not appreciably alter the findings in the spinal fluid. He remained rational most of the time until May 18 when he began to fail rapidly. His spinal fluid became more purulent, and the pressure, which had been below 190 mm. of water during the previous week, again rose above 400. Constant drainage through the lumbar region was established intermittently, but it became necessary to resort to cisternal punctures to obtain fluid for the relief of pressure. He developed, successively, headache, nausea, vomiting, delirium, stupor, coma and pulmonary edema and died on May 23.

Autopsy showed a cortical abscess of the frontal lobe in addition to the acute diffuse purulent meningitis, but no evidence of recent or old infection in the ears, mastoids or accessory nasal sinuses.

Case 2 A 47-year-old, white, obese housewife was admitted from the Out Patient Department on October 18, 1937, for surgery of the accessory nasal sinuses. In the past she had had the usual childhood infections, occasional sore throats, recurrent left otorrhea and, for 2 or 3 years, frequent asthmatic attacks. Both nares were filled with polyps, and all her nasal sinuses were cloudy. The lungs were clear. On October 23 she had a bilateral ethmoidectomy and bilateral radical antrum operation with complete removal of the markedly polypoid mucous membrane, but the bony walls were left intact. The middle turbinates and nasal polyps were removed from both sides of the nose.

On October 25 the patient developed fever and signs of meningitis, and lumbar puncture showed cloudy fluid under increased pressure and Type XAI pneumococci were cultured from the fluid. The following day she received 6 gm of sulfanilamide and, thereafter, 4 gm of the drug was given daily, divided into six doses. Lumbar punctures were done daily until November 7 when she was placed on continuous lumbar drainage. This had to be interrupted frequently because the needle became plugged with thick, fibrinous, purulent exudate. Beginning November 15 cerebrospinal fluid was removed by cisternal puncture. Except for occasional periods of vomiting and delirium she remained conscious and rational until November 18. On that day she became irrational, failed rapidly, became comatose and died the following day. There was no autopsy.

Case 3 A 43-year-old, white woman was admitted to the hospital on January 23, 1938, stuporous and groaning

strated early in the course of pneumococcic infections even in the presence of progressive bacteremia^{2, 6}

It seems reasonable to suppose that, following the use of sulfanilamide, which, as we have noted, results in decreasing the infection in the meninges at least temporarily, small amounts of specific antibody and complement may, in some individuals, reach the infected meninges and not be detectable by the ordinary tests because they are rapidly used up. In this event recovery might take place without further treatment. On the other hand, although our studies in this direction have not yet been completed, it would appear from the data now available that after antipneumococcic horse or rabbit serums are given intravenously, even in the presence of only small numbers of pneumococci, the antibody does not reach the cerebrospinal fluid in demonstrable amounts. It would seem necessary, in most instances, to introduce some antibody into the infected area provided that this could be done without undue risk of severe reactions. After much of the cerebrospinal fluid present before the beginning of sulfanilamide therapy has been drained off by lumbar punctures and the infection reduced by the use of the drug, very small amounts of specific antibody should be sufficient to complete the sterilization of the cerebrospinal fluid provided that there have not yet developed any well-localized areas of abscess formation.

The most readily available supply of antibody which is the least likely to give untoward reactions and at the same time provide complement and an optimum amount of antibody, is the patient's own fresh serum after a balance of specific antibody has been established in the circulating blood.

PROCEDURE ADOPTED

For these reasons we have resorted to the following general procedure:

1 Complete and frequent drainage of the spinal fluid

2 Immediate institution and continuous use of large doses of sulfanilamide by mouth or by subcutaneous injection, if necessary. The optimum dose has not been determined. Sodium bicarbonate is given with each dose.

3 Identification of the pneumococcus as rapidly as possible and the intravenous administration of sufficient specific antipneumococcic serum, to establish a balance of antibody in the circulating blood.

4 Moderate fluid intake by whatever route necessary, to insure adequate amounts of spinal fluid for drainage.

5 About two hours after a reasonable dose has

been given, blood is withdrawn from the patient and serum rapidly separated.

6 Following the removal of spinal fluid at the time of the next lumbar puncture, this serum is given intraspinaly (5 to 10 cc should be sufficient, the optimum amount has not been determined but it is probably small). This procedure may be repeated after subsequent lumbar punctures, if necessary. In small children or in infants it may be necessary to use fresh human serum from another source for complement, and, in that event, only very small amounts of specific therapeutic serum need be added (0.5 cc or less should be sufficient).

7 Lumbar punctures are repeated until the fluid is normal. The frequency is determined by the initial pressure of the fluid and its cellular and protein contents.

8 Transfusions are given after the first week of sulfanilamide therapy if anemia develops, and are repeated, as necessary, until the drug is discontinued (after 7 to 14 days of sterile fluids).

These procedures serve to insure a balance of antibody in the blood stream and to control the bacteremia. They should, in most instances where the sulfanilamide effectively reduces the infection, provide an adequate amount of antibody and complement in the optimum proportions and in a medium which is likely to give the least local or general reaction and the greatest antibacterial effect. The cases to be presented will illustrate the application of some of the principles enumerated.

Intraspinal injections of 15 cc. of fresh human serum from a Group A donor (the patient's blood was Group A) were given on May 14 and 16. The fresh whole defibrinated blood of this donor showed phagocytosis and pneumococidal activity for the patient's organisms, but no agglutinins. These injections did not appreciably alter the findings in the spinal fluid. He remained rational most of the time until May 18 when he began to fail rapidly. His spinal fluid became more purulent, and the pressure, which had been below 190 mm. of water during the previous week, again rose above 400. Constant drainage through the lumbar region was established intermittently, but it became necessary to resort to cisternal punctures to obtain fluid for the relief of pressure. He developed, successively, headache, nausea, vomiting, delirium, stupor, coma and pulmonary edema and died on May 23.

Autopsy showed a cortical abscess of the frontal lobe in addition to the acute diffuse purulent meningitis, but no evidence of recent or old infection in the ears, mastoids or accessory nasal sinuses.

Case 2 A 47-year-old, white, obese housewife was admitted from the Out Patient Department on October 18, 1937, for surgery of the accessory nasal sinuses. In the past she had had the usual childhood infections, occasional sore throats, recurrent left otorrhea and, for 2 or 3 years, frequent asthmatic attacks. Both nares were filled with polyps, and all her nasal sinuses were cloudy. The lungs were clear. On October 23 she had a bilateral ethmoidectomy and bilateral radical antrum operation with complete removal of the markedly polypoid mucous membrane, but the bony walls were left intact. The middle turbinates and nasal polyps were removed from both sides of the nose.

On October 25 the patient developed fever and signs of meningitis, and lumbar puncture showed cloudy fluid under increased pressure and Type XXI pneumococci were cultured from the fluid. The following day she received 6 gm. of sulfanilamide and, thereafter, 4 gm. of the drug was given daily, divided into six doses. Lumbar punctures were done daily until November 7 when she was placed on continuous lumbar drainage. This had to be interrupted frequently because the needle became plugged with thick, fibrinous, purulent exudate. Beginning November 15 cerebrospinal fluid was removed by cisternal puncture. Except for occasional periods of vomiting and delirium she remained conscious and rational until November 18. On that day she became irrational, failed rapidly, became comatose and died the following day. There was no autopsy.

Case 3 A 43-year-old, white woman was admitted to the hospital on January 23, 1938, stuporous and groaning

She responded to painful stimuli but not to questions or commands. It was later learned that she had been sick for 4 weeks with cough and right sided pleurisy.

She was emaciated and pale. The lips and fingertips were moderately cyanotic, and she was shaking as though she were having a chill. The pupils were dilated and reacted sluggishly to light, but the optic disks and retinæ appeared normal. The mucous membranes of the nose and throat were injected. The neck was moderately rigid. There were dullness, bronchial breathing and in

after the beginning of sulfanilamide treatment the patient became rational, but she soon began to fail rapidly in spite of intensive treatment and died on January 29. Autopsy showed the extensive purulent meningitis, or

Figure 2 Case 2. *Pneumococcus* Type XXI meningitis with bacteremia beginning two days after extensive nasal sinus operation. Treatment with sulfanilamide in moderate dosage by mouth begun at first appearance of meningeal signs. Temporary improvement in clinical appearance and in spinal-fluid findings. Failure completely to control the meningeal infection or to prevent the occurrence of bacteremia. Failure to demonstrate specific antibodies (agglutinins) in blood or spinal fluid. Interference with drainage of spinal fluid due to thick exudate. Development of anemia. Progression of symptoms and signs of meningitis. Death on twenty-sixth day. No autopsy.

creased voice sounds over the region of the right upper lobe, but no rales were heard. The heart was slightly enlarged to the left, and a faint diastolic murmur was heard over most of the precordium. The deep reflexes were active and equal. Kernig and Babinski signs were positive on both sides. The blood pressure was 110/80, the red-blood count 3,310,000, the hemoglobin 46 per cent (Sahl), and white blood count 19,400. A roentgenogram of the chest showed an irregular mottled density of the right apex and upper lung field. Lumbar puncture done soon after admission yielded slightly cloudy fluid, the initial pressure being 220 mm. of water. Culture of this fluid showed Type VII pneumococci.

The patient required restraint, and all food and medication were given by nasal tube. Sulfanilamide in large doses was begun shortly after admission. Specific antipneumococcus serum was given intravenously in large divided doses beginning January 26. After the first course of injections the patient was given a single injection of 5 cc. of fresh normal serum intraspinally. Blood culture before the beginning of serum treatment revealed a massive bacteremia and later cultures showed that this was not materially affected by the therapy. For a short time

Figure 3 Case 3. *Pneumococcus* Type VII meningitis with bacteremia four weeks after onset of lobar pneumonia. Intensive treatment with sulfanilamide followed by large doses of concentrated specific antipneumococcus horse serum intravenously. Slight brief improvement in general condition. Failure to control the bacteremia or the meningeal infection. Coexistence of circulating antibodies and heavy bacteremia before serum therapy. Failure to demonstrate specific antibodies in the spinal fluid after intravenous therapy. Failure to influence meningeal infection with single small dose of fresh human serum from a non-immune donor. Death on seventh hospital day. Autopsy: lobar pneumonia, right upper lobe (*Staphylococcus aureus*, *Bacillus mucosus capsulatus* (atypical) and *Hemophilus influenzae*—no pneumococci), obliterative pleuritis—right lung, purulent meningitis (Type VII pneumococcus), vegetative endocarditis of mitral valve (Type VII pneumococcus).

ganizing lobar pneumonia of the right upper lobe, healed pleuritis of the entire right lung, vegetative endocarditis involving the auricular surface of the posterior mitral cusp.

Case 4 A 19-year-old Jewish girl was admitted to the hospital October 30, 1937. She complained of frontal and occipital headaches for 2 months, increasing in severity and occasionally associated with projectile vomiting. For 4 weeks she had been confined to bed with this and with continuous pain in the right upper abdomen and right-lower chest. She had vertigo and dizziness for 2 weeks, and transient blindness followed by diplopia on the day before entry. For 6 months she had had irregular and painful menstruation.

In the past she had had the common childhood infections, occasional sore throats, otitis media many years back, frequent headaches for 2 years, in 1933 an attack of jaundice lasting a month, and excision of an axillary node following an infection of a fingernail. One year before entry she fell on her right temple and lost consciousness for a short while.

Examination showed a fairly well-developed and nourished girl of somewhat inferior mentality, tossing about restlessly, groaning and expressing pain on motion of the

head. There was tenderness over the scalp and abdomen, early choked disks with hemorrhagic retinal exudate and visual disturbances, absent abdominal reflexes, hyperactive deep reflexes, bilateral ankle clonus, general muscular weakness, and past pointing on the finger to nose test. The left eardrum showed thickening with loss of light reflex. Roentgenogram of the skull showed convolitional atrophy indicating increased intracranial pressure. The latter was

arv 31 and then less frequently, a total of one hundred and twenty five punctures being done in all. She developed infection in the tract of the punctures done at the fourth lumbar space and culture from this tract done on January 7 showed Type XVII pneumococci. There were no signs of meningitis at this time and the spinal fluid had become clear. Sulfanilamide therapy was continued until February 8. Improvement in her general condition began on January 8, and except for slight ataxia and lumbar pain on walking, she was symptom free.

Case 5 An 8-year-old white schoolgirl was struck by an automobile at 8 p. m. on February 16, 1938. Except for momentary loss of consciousness at the time of arrival to the hospital she remained alert and rational. There

Figure 4 Case 4 *Pneumococcus* Type XVII meningitis occurring two weeks after extensive cerebellar exploration and incomplete removal of large vascular medulloblastoma. Intensive sulfanilamide therapy by mouth begun with first appearance of fever and meningeal symptoms and maintained. Positive spinal fluid cultures intermittently for two weeks and from abscess in lumbar tract two weeks later. Failure to demonstrate antibodies in blood or spinal fluid. Development of moderate anemia. Gradual recovery with return of spinal fluid findings to within normal limits. Residual ataxia and lumbar pain.

confirmed by lumbar puncture. A diagnosis of posterior fossa tumor was made.

On November 18, bilateral trephine of the skull and ventricular taps were done and fluid in both ventricles found to be under increased pressure. A cerebellar exploration was then done and the largest part of an extensive vascular medulloblastoma was removed piecemeal. The operation was well tolerated, but following it there was considerable vomiting and the patient was given fluids intravenously for several days. On December 2 she complained of pain in the left ear which was apparently due to a furuncle in the external auditory meatus. On the morning of December 3 the patient's temperature rose, and she became drowsy, restless and irrational. She complained of occipital pain and developed signs of meningitis. Lumbar puncture showed cloudy fluid under a pressure of 310 mm. of water. She was immediately started on large doses of sulfanilamide, given by nasal tube at first and later by mouth. Cultures of the fluid showed Type XVII pneumococcus in small numbers intermittently to December 16 and remained sterile thereafter. Lumbar punctures were done three or four times daily until Janu-

Figure 5 Case 5 *Pneumococcus* Type VII meningitis beginning three days after compound fracture of skull through right frontal and temporal bones and criciform plate and one day after extensive debridement. Drainage of spinal fluid through nose. Failure of moderate doses of sulfanilamide given prophylactically to prevent occurrence of meningitis. Administration of concentrated specific antipneumococcal horse serum intravenously and failure, thereafter, to demonstrate specific antibody in the spinal fluid. Maintenance of sulfanilamide therapy and attainment of higher concentration in spinal fluid than in blood after injection of concentrated antipneumococcal horse serum intraspinally. Rapid and permanent control of meningeal infection after single intraspinally injection of small amount of specific antipneumococcal horse serum together with fresh human serum from a non-immune donor, and temporary establishment of a balance of antibody in the spinal fluid. Development of anemia controlled by repeated transfusions. Complete and rapid recovery from meningitis with subsequent healing of operative wound.

was an extensive laceration and evulsion of the scalp with bruises and abrasions of the skin. From the nose there was a profuse bloody discharge which seemed to be mixed with spinal fluid. The eyelids were markedly edematous, completely closing the right eye and partly closing the left. Movement of the spine during and after an unsuccessful attempt at lumbar puncture was painful. There

was no voluntary motion of the neck, but no rigidity. A roentgenogram showed an extensive linear fracture in the frontal region extending just beyond the midline on the left and through the right frontal and temporal bones, with separation of the fragments.

Immediately after admission the patient was started on sulfanilamide 1 gm. every six hours by mouth in an effort to prevent or abort infection of the meninges. The dose was increased 2 days later to 1 gm. every 4 hours.

On February 18, an extensive debridement was carried out under Avertin and ether anesthesia. The operation involved removing a considerable amount of bone just above the bridge of the nose, opening the posterior wall of the frontal sinus and tearing out a piece of dura 1 cm. long, which was impinged in the fracture line that had widened out somewhat as it passed through the cribriform plate. The mucous membrane of the wall of the frontal sinus appeared to be intact. A drain was packed loosely between the torn dura and the fracture line and allowed to protrude from the superior angle of the wound at the bridge of the nose. Another drain was inserted under the right posterior flap of the avulsion and allowed to protrude from the inferior portion of the wound, and the laceration was closed as well as possible. A culture of fluid aspirated from the wound at the operation showed no growth. Following the operation there was considerable seepage of spinal fluid through the frontal drain.

On the day following the operation the patient complained of a "bursting headache," became very restless, and vomited. Fluids were given intravenously. The first successful lumbar puncture was done at 9 p. m. that evening. Cultures of this spinal fluid and of all others obtained during the following 2 days showed Type VII pneumococci. At 3 p. m. on February 21 the patient was given 5 cc. (25,000 units) of concentrated Type VII anti-pneumococcal serum, and 4 hours later 15 cc. (75,000 units) intravenously. At midnight she received intraspinally 0.5 cc. of the same therapeutic serum mixed with 4 cc. of her mother's freshly prepared serum. At the time of the next puncture, the following morning, another 0.5 cc. of the therapeutic serum was given intraspinally. Culture of the spinal fluid obtained before the first intraspinal injection showed Type VII pneumococci, but the fluid obtained the following morning and all subsequent fluids remained sterile. The spinal fluid findings soon became normal. There was a slight transient urticaria on February 23, and weakness of the left arm for a few days. There was no further evidence of meningeal infection, however, and the wound began to granulate in slowly.

Case 6 A 17-year-old white boy was involved in an automobile collision at 9 p. m. on March 9, 1938. He was treated for lacerations over the parietal region but returned later because of severe headaches and was admitted to the hospital on the following morning.

The patient had been followed in the Out Patient Department and 2 years previously had been admitted to the hospital because of epileptic seizures. He was said to have been dropped on his head at the age of 10 months. He had had mumps, measles and whooping cough, and had occasional headaches. In 1931 he was run over by an automobile and sustained a compound fracture of the right leg. In 1934 he had had a severe epistaxis following an injury.

At the time of admission there was a hematoma of the right eyelids, an abrasion over the bridge of the nose, and a laceration over the right parietal region. The reflexes were hyperactive on both sides. A lumbar puncture done at this time showed clear fluid and no increased pressure. During the next 2 days, however, the spinal

fluids were cloudy and under increased pressure, and cultures of these fluids showed Type XXVIII pneumococci. On March 12 it was first noticed that the patient had become totally deaf, and he remained so throughout his stay in the hospital.

Treatment with sulfanilamide, 1 gm. every 4 hours, was begun on the morning after admission. This dosage was increased at irregular intervals thereafter. Repeated lumbar punctures were done as indicated by the pressure and spinal fluid findings. Cultures of the spinal fluids remained positive, with some exceptions, until March 25. By March 21 the patient's general condition appeared to be getting worse. Following the first lumbar puncture

Figure 6 Case 6 *Pneumococcus* Type XXVIII meningitis following head injury with bleeding from both ears. Development of complete deafness the first day after onset of meningitis. Intensive sulfanilamide therapy by mouth beginning with the first evidence of infection. Stormy course with intermittent positive spinal fluid cultures for two weeks. Failure to demonstrate specific agglutinins in the blood or spinal fluid (phagocytic and pneumococcal activity demonstrated in the patient's whole defibrinated blood). Persistence of positive spinal fluid cultures after two intraspinal injections of patient's own fresh serum and control of the infection after the third injection. Development of progressive anemia with partial relief after daily transfusions for two weeks. Recovery from meningitis with persistence of deafness.

on that day, and again after the punctures done on March 22 and 25, he was given 10 cc. of his own serum, freshly prepared, intraspinally. This serum showed no agglutinins, but the whole defibrinated blood showed marked phagocytosis and pneumococcal activity for a culture of the organisms grown from the patient's own spinal fluid. Because of the progressive development of anemia he was given daily transfusions of 250 or 200 cc. of whole citrated blood for 2 weeks, with some improvement in the blood picture. The sulfanilamide was discontinued on April 5. The patient was observed in the hospital until May 13 and showed progressive improvement during that time. His nutritional state, which had declined progressively, began to improve rapidly after the first week in April.

Case 7 A 10-year-old white schoolboy was admitted to the hospital on April 9, 1938, complaining of frontal headache and fever of 3 days duration. On the day of admission he began to vomit and developed a stiff neck. One year previously he had acute otitis media, and since that time he had purulent discharge off and on from the left ear. There was some dried purulent exudate in the left external canal, the drum was retracted except in the inferior portion which was red and contained a postero-marginal perforation. There was no mastoid tenderness. Culture of the exudate from the left ear showed Type III pneumococci. There was some hyperemia of the nasal mucous membranes. The neck was rigid, and the Kernig and Brudzinski signs positive on both sides. Roentgenograms showed the mastoid tips to be clear. Lumbar punctures done on admission and again the following day showed slightly cloudy fluid under pressure of 300 and 370 mm. of water, respectively, but cultures of these fluids showed no growth and smears of the sediment showed no organisms.

Figure 7 Case 7 *Pneumococcus Type III meningitis complicating chronic otitis media and mastoiditis. Mastoidectomy with exposure of dura. Intensive sulfanilamide therapy by mouth with failure completely to relieve the meningeal infection in ten days. Demonstration of specific antibodies in the circulating blood during active meningeal infection and failure to demonstrate antibodies in the spinal fluid at the same time. Complete and permanent control of meningeal infection after first intraspinal injection of patient's own fresh serum. Recovery.*

Sulfanilamide was given by mouth beginning the morning after admission. On May 11 a radical mastoidectomy was done. Purulent mucus was found on entering the antrum and culture of this exudate showed Type III pneumococci. The dura and lateral sinus were exposed and found to be normal. Necrotic tissue was curetted from around the lateral semicircular canal and the lateral sinus. Signs of meningitis persisted, and except for two spinal fluids obtained during the first 3 days after the operation, repeated lumbar punctures until April 18 yielded fluid from which Type III pneumococci were cul-

tured. The blood serum of the patient on March 15 failed to show agglutinins for Type III pneumococci, but they were demonstrated in the serum of April 18. On the latter date the culture of the spinal fluid was still positive for Type III pneumococci, and after this fluid was withdrawn 5 cc. of the patient's own freshly prepared serum was injected intraspinally. All subsequent lumbar punctures yielded fluids which showed no growth on culture. A second intraspinal injection of the patient's fresh serum was given on April 19. Thereafter, the patient made an uneventful recovery. Mouse protection tests carried out later showed that the serums of April 15 and 18, in 0.2 cc. amounts, protected mice against 1000 and 10,000 fatal doses of Type III pneumococci, respectively. The spinal fluids of the same dates showed no protection.

Case 8 A 7-year-old white boy was struck on the head and face by a falling plank on April 12, 1938. He lost consciousness for a brief period and, shortly thereafter, was brought to the hospital. The patient was a third child and was delivered with forceps without difficulty. He had had the usual childhood diseases and occasional tonsillitis.

Figure 8 Case 8 *Pneumococcus Type XIV meningitis occurring 16 days after fracture of skull above right orbit and a few hours after a blow over the dorsal spine. Heavy infection of spinal fluid. Intensive sulfanilamide therapy by mouth followed by intravenous injection of specific antipneumococcal rabbit serum. Establishment of balance of homologous specific antibodies in the circulating blood and failure to demonstrate such antibodies in the spinal fluid after the intravenous injections. Rapid and complete control of meningeal infection after the first intraspinal injection of the patient's own fresh serum containing homologous antibody and establishment of a temporary balance of specific antibody in the spinal fluid. Development of anemia with improvement after repeated transfusions. Rapid and complete recovery.*

One year previously he had had a left otitis media. On examination, blood was seen oozing from the nose, and there was an area of ecchymosis over the right eye, but the child was conscious and rational. The tendon reflexes were hyperactive, there was a positive Kernig sign on

was no voluntary motion of the neck, but no rigidity. A roentgenogram showed an extensive linear fracture in the frontal region extending just beyond the midline on the left and through the right frontal and temporal bones, with separation of the fragments.

Immediately after admission the patient was started on sulfanilamide 1 gm. every six hours by mouth in an effort to prevent or abort infection of the meninges. The dose was increased 2 days later to 1 gm. every 4 hours.

On February 18, an extensive debridement was carried out under Avertin and ether anesthesia. The operation involved removing a considerable amount of bone just above the bridge of the nose, opening the posterior wall of the frontal sinus and tearing out a piece of dura 1 cm. long, which was impinged in the fracture line that had widened out somewhat as it passed through the cribriform plate. The mucous membrane of the wall of the frontal sinus appeared to be intact. A drain was packed loosely between the torn dura and the fracture line and allowed to protrude from the superior angle of the wound at the bridge of the nose. Another drain was inserted under the right posterior flap of the avulsion and allowed to protrude from the inferior portion of the wound, and the laceration was closed as well as possible. A culture of fluid aspirated from the wound at the operation showed no growth. Following the operation there was considerable seepage of spinal fluid through the frontal drain.

On the day following the operation the patient complained of a 'bursting' headache, became very restless, and vomited. Fluids were given intravenously. The first successful lumbar puncture was done at 9 p. m. that evening. Cultures of this spinal fluid and of all others obtained during the following 2 days showed Type VII pneumococci. At 3 p. m. on February 21 the patient was given 5 cc. (25,000 units) of concentrated Type VII anti-pneumococcal serum, and 4 hours later 15 cc. (75,000 units) intravenously. At midnight she received intraspinally 0.5 cc. of the same therapeutic serum mixed with 4 cc. of her mother's freshly prepared serum. At the time of the next puncture, the following morning, another 0.5 cc. of the therapeutic serum was given intraspinally. Culture of the spinal fluid obtained before the first intraspinal injection showed Type VII pneumococci, but the fluid obtained the following morning and all subsequent fluids remained sterile. The spinal fluid findings soon became normal. There was a slight transient urticaria on February 23, and weakness of the left arm for a few days. There was no further evidence of meningeal infection, however, and the wound began to granulate in slowly.

Case 6 A 17-year-old white boy was involved in an automobile collision at 9 p. m. on March 9, 1938. He was treated for lacerations over the parietal region but returned later because of severe headaches and was admitted to the hospital on the following morning.

The patient had been followed in the Out Patient Department and 2 years previously had been admitted to the hospital because of epileptic seizures. He was said to have been dropped on his head at the age of 10 months. He had had mumps, measles and whooping cough, and had occasional headaches. In 1931 he was run over by an automobile and sustained a compound fracture of the right leg. In 1934 he had had a severe epistaxis following an injury.

At the time of admission there was a hematoma of the right eyelids, an abrasion over the bridge of the nose, and a laceration over the right parietal region. The reflexes were hyperactive on both sides. A lumbar puncture done at this time showed clear fluid and no increased pressure. During the next 2 days, however, the spinal

fluids were cloudy and under increased pressure, and cultures of these fluids showed Type XXVIII pneumococci. On March 12 it was first noticed that the patient had become totally deaf, and he remained so throughout his stay in the hospital.

Treatment with sulfanilamide, 1 gm. every 4 hours, was begun on the morning after admission. This dosage was increased at irregular intervals thereafter. Repeated lumbar punctures were done as indicated by the pressure and spinal fluid findings. Cultures of the spinal fluids remained positive, with some exceptions, until March 25. By March 21 the patient's general condition appeared to be getting worse. Following the first lumbar puncture

Figure 6 Case 6 *Pneumococcus* Type XXVIII meningitis following head injury with bleeding from both ears. Development of complete deafness the first day after onset of meningitis. Intensive sulfanilamide therapy by mouth beginning with the first evidence of infection. Stormy course with intermittent positive spinal fluid cultures for two weeks. Failure to demonstrate specific agglutinins in the blood or spinal fluid (phagocytic and pneumococcal activity demonstrated in the patient's whole defibrinated blood). Persistence of positive spinal-fluid cultures after two intraspinal injections of patient's own fresh serum and control of the infection after the third injection. Development of progressive anemia with partial relief after daily transfusions for two weeks. Recovery from meningitis with persistence of deafness.

on that day, and again after the punctures done on March 22 and 25, he was given 10 cc. of his own serum, freshly prepared, intraspinally. This serum showed no agglutinins, but the whole defibrinated blood showed marked phagocytosis and pneumococcal activity for a culture of the organisms grown from the patient's own spinal fluid. Because of the progressive development of anemia he was given daily transfusions of 250 or 200 cc. of whole citrated blood for 2 weeks, with some improvement in the blood picture. The sulfanilamide was discontinued on April 5. The patient was observed in the hospital until May 13 and showed progressive improvement during that time. His nutritional state, which had declined progressively, began to improve rapidly after the first week in April.

were generally diminished. Lumbar puncture yielded purulent fluid under increased pressure, with numerous organisms that were rapidly identified by direct smear, microscopic agglutination and Neufeld's capsular swelling reactions as Type IV pneumococci. Blood culture taken at this time also showed Type IV pneumococci, and these organisms were also obtained from cultures of the nose and throat and of the purulent discharge from the left ear. The patient was immediately given 2 gm. of sulfanilamide by stomach tube and 1 gm. every 4 hours thereafter. Intravenous administration of repeated small doses of anti pneumococcus Type IV rabbit serum was begun at 2 p.m.

During the succeeding hour the pulse became irregular and thready. Stimulants were given but the child failed to respond.

Autopsy done 15 hours after death showed the brain to be edematous and injected. Over the convexities there was a perivascular, greenish yellow exudate. There was similar purulent material at the base of the brain, especially around the optic chiasm and infundibulum. No abscesses were made out in sections of the brain. Both middle ears were full of green pus. The spinal cord was hyperemic with thickening of the leptomeninges. The lumbar space was completely filled with thick, fibrino-

Figure 10 Case 10 *Pneumococcus* Type IV meningitis with bacteremia complicating otitis media. Treatment with sulfanilamide by mouth, intravenous specific antipneumococcal rabbit serum and similar serum mixed with fresh non-immune human sera intraspinally. Untoward reactions following intravenous injections. Block due to thick exudate and edema. Failure to grow pneumococci from lumbar and cisternal fluid after treatment. Death after thirty-two hours. Autopsy: bilateral acute otitis media, acute purulent meningitis, mild pulmonary congestion. Type IV pneumococci were cultured from the cortex of the brain but no organisms were grown from cultures of the lumbar, cisternal and ventricular fluids.

At this time the temperature was 105.4°F, and the pulse 178 and feeble. One hour after the first injection of 0.5 cc. the temperature rose to 107.4°F (rectally), and the pulse to 184, and the child had a convulsion followed by pulmonary edema and peripheral circulatory collapse. She improved after treatment with caffeine, intravenous 30 per cent glucose and oxygen inhalation. Subsequent doses were followed by slight motor activity without rise in temperature or pulse rate. Following each of the next three lumbar punctures she was given 0.5 cc. of the specific therapeutic rabbit serum and 4.5 cc. of fresh non-immune human serum intraspinally. At noon the following day a lumbar puncture was unsuccessful. A cisternal puncture was done, and a similar mixture of Type IV rabbit and fresh human serum was injected after removal of fluid. The last intravenous injection was given at 6:30 p.m. on May 19 at a time when the child was obviously mori-

purulent exudate. There was slight pulmonary congestion, and a few enlarged mesenteric nodes were noted in the abdomen. Cultures of fluid removed under aseptic precautions by lumbar and cisternal puncture and by puncture of each ventricle showed no growth except in the broth culture of the lumbar fluid, which contained colon bacilli. A culture taken from the cortex of the brain, however, showed a pure culture of Type IV pneumococci. A culture from the purulent exudate at the base of the brain showed a few colon bacilli but no pneumococci.

SUMMARY AND CONCLUSIONS

A method of treatment for meningitis due to specific types of pneumococci is described and the results of the bacteriological and immunological studies upon which it is based are reviewed.

both sides, and the Babinski sign was positive on the left. Roentgenograms of the skull showed a medial fracture above the right orbit. A lumbar puncture done on admission yielded pink fluid under normal pressure, and spinal fluid obtained on April 14 was clear. The patient's temperature and pulse rate were slightly elevated for the first 36 hours in the hospital but thereafter were normal. He rapidly became and remained free of symptoms and was discharged home on April 25.

Two days after discharge, while at play, he was kicked in the small of his back by one of his mates. Almost immediately thereafter he complained of headache and pain in the back and began to vomit all food. He was put to bed but became feverish and his symptoms increased progressively. He was readmitted to the hospital at 2 a. m. on April 28, at which time he showed typical signs of meningitis. A lumbar puncture showed purulent fluid under increased pressure. Culture of this and of subsequent fluids showed Type XIX pneumococci. Sulfanilamide therapy was instituted immediately after admission. Lumbar puncture at 2 p. m. yielded fluid which, in appropriate dilutions in blood agar-plate cultures showed approximately 900,000 colonies per cubic centimeter. At 4 30, 6 30 and 8 30 p. m. the patient was given 1, 9 and 20 cc., respectively, of homologous antipneumococcal rabbit serum intravenously. At 8 p. m. blood was withdrawn from the patient, and serum freshly prepared from it. At 9 p. m. another lumbar puncture was done, and culture of the fluid obtained showed 5000 colonies per cubic centimeter. After this fluid was withdrawn 5 cc. of the patient's freshly prepared serum was given intraspinally. On the following day two more intraspinal injections of 6 and 3 cc., respectively, of serum prepared from the blood of the patient obtained in the morning were given. Beginning with the fluid obtained at 2 a. m. on April 19, cultures of all spinal fluids showed no growth. The patient showed no further signs of meningeal infection and improved progressively. Each of the samples of the patient's serum that were given intraspinally showed a good titer of agglutinins for Type XIX pneumococci. The patient developed a slight progressive anemia which was controlled by transfusions while the sulfanilamide therapy was maintained.

Case 9 A 13-year-old schoolboy was admitted to the hospital at 4 a. m. on May 15, 1938. A week prior to entry he had a common cold with herpes. On the evening of May 10 he got wet and had chills. He soon developed headache, malaise and stiff neck. These symptoms continued until the day of entry when he became drowsy and prostrated. There was no history indicating any recent injury or aural or sinus infection. At the age of 6 he had had a splenectomy because of persistent splenomegaly and leukocytosis since early childhood. At the time of admission the patient was toxic and disoriented, his neck was rigid, there was marked muscular weakness of the extremities, and bilaterally positive Kernig and Brudzinski signs. Lumbar puncture yielded purulent fluid under a pressure of 300 mm. of water. Culture of this fluid showed Type XXVIII pneumococci, about 20,000,000 per cubic centimeter.

Sulfanilamide therapy by mouth was begun forthwith. On May 17 he became and remained rational and alert. On that day he received 40 cc. of homologous antipneumococcal rabbit serum intravenously between 4 and 7 30 p. m. At 9 p. m. some of the patient's blood was withdrawn and serum drawn off. One cubic centimeter of therapeutic rabbit serum was added to 5 cc. of the patient's freshly prepared serum, and the mixture given intraspinally after the next lumbar puncture, which was done at 11 p. m. Cultures of all subsequent spinal fluids

showed no growth. Five more similar injections were given during the next 2 days. The initial pressure at the time of the various lumbar punctures from the day after admission until the one done at 10 a. m. on May 20 was between 340 and 500 mm. of water. Thereafter the pressure gradually returned to normal. The patient began to improve progressively after the first intraspinal injection.

Figure 9 Case 9 Primary (?) Type XXVIII pneumococcus meningitis in a patient with persistent leukocytosis seven years after splenectomy. Intensive treatment with sulfanilamide by mouth with improvement in general condition and in spinal-fluid findings. Injection of specific antipneumococcal rabbit serum intravenously. Rapid establishment of a balance of specific antibodies in the circulating blood and failure to demonstrate them in the spinal fluid after the intravenous injections. Intraspinal injection of patient's fresh serum mixed with small amounts of specific antipneumococcal rabbit serum. Rapid and complete clearing of meningeal infection and recovery.

His meningeal symptoms cleared and spinal fluid findings returned to normal. On May 18 his left wrist was noted to be swollen and tender. This swelling receded somewhat on the next day. On May 21 there was slight tenderness and swelling of the left elbow and over the left biceps muscle. These symptoms rapidly cleared. He developed urticaria on May 26.

Case 10 A 3-year-old white girl was admitted to the hospital on May 18, 1938. On May 11 the patient developed otitis media with a foul smelling, purulent discharge from the left ear. She improved during the next 2 days. On May 16 she became drowsy, refused food, had fever and malaise, and vomited several times. On the following day she became semicomatose, and her mother observed that her neck was stiff. Her condition became steadily worse. At the time of admission the child was comatose, with rapid respirations and stiff neck. Her eyes were rolled outward and showed slight lateral nystagmus. The left eardrum was white and bulging, and the right was slightly injected. The tonsils showed scarring and exudate. The chest was clear. There were positive Kernig and Brudzinski signs bilaterally. The deep tendon reflexes

THE OPERATIVE MORTALITY OF CHOLECYSTITIS

BOSTON

STATISTICAL study of series of cases is a valuable method for the surgeon to evaluate the efficacy of his treatment. This study was undertaken in an effort to add to the knowledge of the mortality risks incurred by patients undergoing gall-bladder surgery.

That there is need for improvement in the mortality rates in gall-bladder surgery is evident since it has remained consistently high in spite of efforts to lower it. It seems apparent that several factors have contributed to maintain a high rate. The use of various diagnostic x-ray procedures has widened the accepted indications for operation. Also the improvement in surgical technic has made surgical treatment appear simpler and less tedious than medical. The result has been an increasing frequency of the employment of surgery which has engendered a feeling of increasing safety. This in turn has given rise to a complacency which has failed to subject mortality rates to sufficient consideration. Recently, surgeons have begun to realize that the operative treatment of cholecystitis has not been so satisfactory as they had hoped. A consideration of the failure to relieve some patients of their symptoms has also revived interest in the consideration of the morbidity and mortality rates. Several studies reviewing the results in living post-operative cases have appeared in the recent literature, but no study of the mortality rates covering such a large group as that here presented has been published. Particular emphasis in this study is placed on the effect of combining appendectomy with gall-bladder procedures.

group is analyzed according to the operative procedures employed, and the sex and age of the patient. The cases with lithiasis are further considered under three pathological categories: acute, subacute and chronic.

The acute, chronic and subacute groups do not represent the chronicity of symptoms, but rather the histological degree of inflammation. Often, in fact usually, the acute condition is found in a gall bladder which has been the seat of a protracted chronic condition with lithiasis, no acute cases occurred in this series in stoneless gall bladders. The etiology and pathology will not be discussed further in this paper.

The fatal cases are reviewed to determine the preoperative preparation, the means of diagnosis and the primary cause of death. No attempt has been made to study the cases from the standpoint of the technical methods employed. The series represents the work of several operators.

The total number of cases are also considered from the standpoint of the operation employed in relation to other diseases present (Table 2). It is astonishing to see the great variety of procedures that have been combined in gall-bladder surgery. The herniorrhaphies are not qualified in the list, but they represent ventral, incisional and inguinal operations. Nor has the operative procedure known as lysis of adhesions been listed, as practically every case of cholecystitis here covered showed either inflammatory or congenital adhesions around the gall bladder or duodenum. All the listed operations were performed at the same time.

The incidence of combined appendectomy and cholecystectomy in this series is 45.9 per cent. Unquestionably only the better-risk patients were subjected to both operations. The increased rate for the cases without appendectomy represents the general run of risks, whereas the cases with appendectomy represent a preferred-risk group.

An appendectomy was performed in 49.8 per cent of the stoneless cases, and in 43 per cent of the stone cases. The mortality rates again show lower figures in the appendectomy group. Appendectomy was performed only on those patients who were standing the operation well. With a generous right upper rectus or oblique incision, the appendix is usually brought into view easily and without any shock from undue handling of the viscera. In cases where there were pericecal adhesions and the symptoms or x-ray findings demanded an ap-

Table 1 *Classification of Cases*

TYPE OF CHOLECYSTITIS	NO. OF CASES	DEATHS
Chronic without lithiasis	389 (38%)	35 (9.0%)
Cholecystitis with lithiasis		
Chronic	440 (44%)	53 (12.1%)
Acute	161 (16%)	17 (10.6%)
Subacute	28 (2%)	2 (7.1%)
Totals	629 (62%)	72 (11.4%)
Grand totals	1018	107 (10.5%)

Our series consists of 1018 cases of cholecystitis treated by surgery on the services of the Massachusetts Memorial Hospitals from 1924 through 1933 (Table 1). Only cancer cases have been excluded. The cases are divided into two main groups: those with lithiasis and those without. Each

From the Surgical Service of the Massachusetts Memorial Hospitals and the Department of Surgery, Boston University School of Medicine.

*Assistant in surgery and anatomy, Boston University School of Medicine; second assistant surgeon to house and outpatients, Massachusetts Memorial Hospitals.

The essentials of the treatment are (1) immediate administration of large doses of sulfanilamide and maintenance of this dosage, (2) intravenous injection of specific antipneumococcic serum, (3) intraspinal injection of the patient's own fresh serum after the establishment of a balance of antibody in the blood, or the use of small doses of specific antiserum, together with fresh human serum, (4) frequent drainage by lumbar puncture

The data in 10 cases of pneumococcic meningitis treated with sulfanilamide alone or with this drug in various combinations with specific serum and complement are presented to illustrate various aspects of the treatment

Six of the patients recovered. The most rapid recoveries occurred in the 4 cases in which the treatment was carried out as outlined above

Further studies in a large number of cases are necessary before the various aspects of this mode of treatment can be properly evaluated

This study was made possible through the most generous co-operation of the members of the visiting and resident staffs of eight different services at the Boston City Hospital who either transferred their cases to the Neurosurgical and Neurological Services or carried out the details of the treatment on their own wards

The surgical operations were performed in Case 2 by Drs P Leo O'Connell and J Paul Tierney, in Case 4 by Drs Walter Wegner and Charles G Freed, in Case 5 by Drs Freed and Rauh, and in Case 7 by Dr Samuel W Garfin. Dr Garfin later permitted his patient to be transferred to the Neurological Service for treatment.

Dr Edward C Curnen assisted in the study of some of these cases. Mrs Mildred W Barnes assisted in the bacteriological and immunological studies. Miss Helene Coffey carried out the chemical studies on the spinal fluids. Miss Marjorie L. Jewell made the determinations of

sulfanilamide. Miss Marion E Lamb and Miss A Kathleen Daley assisted in the bacteriological studies and the type determinations

We are particularly indebted to Dr W G Malcolm, executive director of the Lederle Laboratories, Inc., Pearl River, New York, who provided us with the therapeutic serums used in this study

Our series consists of 1018 cases of cholecystitis treated by surgery on the services of the Massachusetts Memorial Hospitals from 1924 through 1933 (Table 1). Only cancer cases have been excluded. The cases are divided into two main groups: those with lithiasis and those without. Each

From the Surgical Service of the Massachusetts Memorial Hospitals and the Department of Surgery, Boston University School of Medicine.

Assistant in surgery and anatomy, Boston University School of Medicine; second assistant surgeon in chief and outpatient, Massachusetts Memorial Hospitals.

pendectomy, a separate lower rectus incision was made. The number of patients who had had a previous appendectomy was not determined. In the stoneless group 159 patients had cholecystectomy and appendectomy and 152 had cholecystectomy alone. The mortality rates for those with and without appendectomy are practically identi-

tical. "Routine" operations are included those dealing directly with the gall-bladder disease, plus appendectomy, because it was so frequently employed. Under "combined" operations are included all other procedures which were performed at the same time. "Combined" is thus used in contrast to "multiple" for the latter term denotes operative

Without appendectomy	355	50	14.0	196	21	10.7	551	71	12.8

a greater incidence of combined appendectomy because it represents patients with indefinite digestive symptoms and with poor filling and emptying of the gall bladder. At operation the pathological findings around the gall bladder were not extensive, and in a further attempt to explain and improve the symptoms the appendix was explored and removed. It is also in this group of stoneless cases that the poorest subjective results are usually found, this is due in no small measure to the indefinite association of the gall bladder to the symptoms.

The operative procedures were tabulated under routine and combined operations. Under "rou-

ting" to the operative procedures employed in the presence of varying degrees of gall-bladder disease. It was felt that the higher figure for routine operations would thus be explained.

Table 4 *Combined and Routine Operations*

TYPE OF OPERATION	NO	DEATHS	MORTALITY RATE %
Routine	852	92	10.8
Combined	166	15	9.0
Totals	1018	107	10.5

The death rate in acute cholecystitis agrees with that found in many clinics. The low rate of 5.1 per cent in the patients on whom appendectomy was

also performed again brings out the fact that only the best-risk patients were so treated. Cholecystostomy carries a very high mortality rate in this series. In acute cholecystitis the figure is similar to that given by Babcock¹ for the mortality from cholecystostomy. Certainly in this hospital cholecystectomy has given better results in every pathologic group. The high rate is probably due to the fact that the operation was reserved for aged and poor-risk patients. Any procedure on an acutely inflamed, gangrenous gall bladder may be too much for a critically ill patient. Yet cholecystostomy in the chronic conditions carried a higher mortality rate than did cholecystectomy. Even though the procedure was performed under local anesthesia, the shock was still enough to bring death to 1 out of every 3 patients.

From this table it can be seen that while there were only 197 male patients (18 per cent), 41 (38 per cent) terminated fatally. It was believed that it would be of interest to see what pathological grouping would show for the sexes. Men are accused of allowing symptoms to go on for a long time before seeking advice. The table does not bear this out, as more men are found in the stoneless cases, and only a slightly smaller percentage of women than men are found among the more urgent operative types of disease, such as acute, gangrenous and subacute.

Twenty per cent of the men showed acute or subacute pathologic lesions, compared with 16 per cent of the women. On the other hand, 55.7 per cent of the men had no stones, whereas only 36.3 per cent of the women had none. In spite of the

Totals	161	17	10.5	28	2	7.7	440	53	10.2	389	35	9.0

Appendectomy combined with cholecystectomy shows as low if not lower mortality rates in every pathological group than cholecystectomy alone. It is safe to say that when properly done on a good-risk patient it does not increase the hazard appreciably. In no case could the appendectomy be blamed for death due to sepsis.

Major procedures should not be combined with gall-bladder surgery unless the patient is an excellent risk and the gall-bladder procedure is relatively easy. Except in gastric surgery the results have been fairly good. Yet 2 patients were lost whose extensive ventral hernias were repaired. Herniorrhaphy tends to be a time-consuming operation and may well increase the incidence or the severity of shock. The combining of gastric procedures doubles the risk and should be condemned. The record of 43 vaginal and pelvic procedures without a fatality shows that the cases were well selected. In spite of the favorable figures here shown pelvic procedures should be done at a separate operation.

The sex incidence of the group was determined. The classic distribution shows gall-bladder disease to be four times as frequent among women as among men. Our figures very closely approximate these figures.

fact that the stoneless cases should represent a better operative prognosis, as there should be less liver damage, adhesions and other operative difficulties, the mortality rate among the men was appalling.

Table 6 *Sex Incidence by Pathology*

PATHOLOGICAL CLASSIFICATION	MALES			FEMALES		
	NO	DEATHS	MORTALITY RATE %	NO	DEATHS	MORTALITY RATE %
Acute	33	10	30	128	7	6
Subacute	8	2	25	20	0	0
Chronic with stone	55	14	25	385	39	10
Chronic without stone	101	15	17	258	20	7
Totals	197	41	21	821	66	8

Table 6 shows that men are decidedly poorer risks than women.

The age incidence chart (Fig 1) shows that 45 per cent of the operations occurred in patients from forty to sixty years of age. Another 25 per cent occurred in those aged thirty to thirty-nine. The peak of the incidence occurred in the fifties. The fact that this peak occurs here rather than in the forties, as given in the trilogy "far, fat and forty" is most probably due to postponement of operation for some time after the onset of symptoms. The

average duration of symptoms prior to operation in this series was six years

Youth and old age show a higher percentage of acute than of chronic disease, 12 per cent of the acute cases occurred under twenty years and 55 per cent occurred after seventy, whereas 0.2 per cent of the chronic cases occurred under twenty and 36 per cent after seventy

The death rates show a constant curve in all

Figure 1 Incidence and Mortality Chart The 1013 cases are charted for number by the continuous line and for mortality percentage by the broken line (the age was doubtful or missing in 5 records) The acute upswing for mortality per cent after the age of sixty is most striking On dividing the cases according to the type of cholecystitis—acute, subacute and chronic—and on charting the number of cases and mortality percentage, similar curves were obtained in each group

types of disease, up to the age of twenty no deaths occurred, from twenty to sixty the slope is constant, from sixty on the curves rise very rapidly, until in the seventies the death rate reaches 35 per cent Except for the subacute group, which is too small to draw conclusions from, there is so little difference in the curves for the different pathological groups that one is tempted when considering operative risks to place more prognostic value on the age of the patient than on the degree of disease

Bearing in mind that men seemed the poorer risks in this series, the age incidence by sexes was determined The average age of the men in the acute group was fifty-eight, in the chronic group fifty-four and in the subacute group fifty-three. The ages of the women were forty-five in the acute group, forty-eight in the chronic group and forty-five in the subacute group The men show from eight to fourteen years advanced age over the women in each group This fact probably has some bearing on the higher mortality rates among the

men Both the highest mortality rate and the greatest average age occurred in the acute group and among the men On the other hand, the lowest mortality rate and the lowest average age occurred in the acute group and among the women The difference in age between the acute male and female cases was almost fourteen years, but it seems unlikely that this difference can account wholly for the twenty-four per cent difference in mortality rates

Age plays an important part in the prognosis of the operative results of gall bladder procedures Patients must be prepared very carefully for operation In elective operations every effort must be made to evaluate cardiac, renal and hepatic efficiency so that each may be brought to as high a state as possible prior to operation In emergency operations one can profitably delay them a few hours so as to make determinations of blood non-protein nitrogen, chlorides, carbon-dioxide combining power and icteric index, and to administer intravenous saline and glucose solutions A carbon-dioxide determination below 36 vol per cent is a definite contraindication to surgery No case is so urgent but that the patient's chances will be improved by immediate operation and hence, a delay in administering supportive treatment The failure to learn this lesson earlier contributed to our high mortality rate in cholecystostomy Many of our fatal cases were operated upon immediately upon hospital entry and death occurred within a few hours after operation, or even on the table If these patients had been given preoperative preparation some might have died unoperated Yet for the majority the operative risk would have been lowered by a preoperative pause to administer fluids, glucose, or even blood, if necessary These principles apply to patients of all ages In people over sixty, since the degenerative processes of age have usually made heavy inroads on stamina, special care is imperative if one is to avoid an appalling mortality rate

An analysis of the fatal cases was made in an effort to determine whether the fatal operations were elective or emergency ones, and whether the diagnosis and basis for operation were determined by clinical or by x-ray findings As shown in Table 7, seventy-three per cent of the deaths occurred in elective operations Sixty-eight per cent of the deaths in stone cases and 82 per cent in stoneless cases were operations of choice The primary symptoms and complaints have not been listed Some of the emergency operations were undertaken under a provisional diagnosis of intestinal obstruction or acute pancreatitis It was only at operation that the true nature of the disease was found

The preoperative stay of the fatal stone cases averaged four days and of the stoneless cases three. However, 54 of the 107 fatal cases were in the hospital less than twenty-four hours before operation. Such a stay is too brief for adequate preparation for operation, or for proper evaluation of its necessity, and must be discouraged.

X-ray studies were recorded in 30 stone cases and 13 stoneless cases which resulted in death. A positive x-ray diagnosis was made the apparent

Table 7 *Analyses of 107 Fatal Cases*

	DEATHS	WITH STONES	WITHOUT STONES

basis for operation in 18 of the former and 10 of the latter. In the early years of this series the Graham test was not in use. Some of the patients had received x-ray studies at other clinics. In the last four years practically every patient had had some x-ray study. In 28 cases x-ray evidence rather than the clinical story swayed the decision to operate.

No cause other than operation	11
Total	107

31 per cent of these cases were autopsied.

The causes of death (Table 8) are those usually associated with abdominal surgery. Pneumonia, peritonitis and cardiac failure accounted for over half the fatalities. The depredations of degenerative disease, such as generalized arteriosclerosis, coronary sclerosis, chronic vascular nephritis and myocardial fibrosis, were frequent contributors. Hemorrhage, which is usually considered a severe and frequent complication of gall-bladder surgery, caused only 4 deaths.

Among the 161 acute cases there were 17 deaths. Of these 6 occurred following perforation of the gall bladder, 8 after gangrene and 1 after empyema of the gall bladder. Only 2 of the fatal cases showed no septic complications, as 1 patient died from hemorrhage and 1 from surgical shock. In 15 death was caused by sepsis, the patients showing late phases of an acute process. All these cases had been treated expectantly at home or in

the hospital. Early operation, after the administration of restorative fluids, would at least have avoided the occurrence of perforation. Whether the mortality rate would have still remained as high if earlier operation had been attempted is a matter of conjecture. There has been considerable discussion of late concerning the proper handling of acute cholecystitis as to whether operative interference should be early or delayed. This question cannot be answered here, but we can point to a group of severe complications which resulted from too great delay in operating. The expectant or delayed operative treatment of acute cholecystitis must be carried out with the frequent occurrence of complications due to gangrene and perforation ever in mind. No rule can be formulated, but a waiting course is justified only if improvement is taking place.

CONCLUSIONS

From the foregoing material the following conclusions and recommendations can be drawn.

The procedures of cholecystectomy and cholecystostomy must still be considered serious operations, with potentialities for a high mortality rate.

Appendectomy is unlikely to increase the operative risk if cases are properly selected.

Gall-bladder operations combined with any other major procedure carry too great a hazard to justify them except in distinct emergencies.

In cases presenting multiple surgical diseases a two-stage operation should be done, the more urgent condition being treated at the first operation and the less urgent condition two or more weeks later.

Women are better operative risks than men. In this series there was a higher incidence of operations and a lower mortality rate among women.

Gall-bladder surgery in people over sixty carried a mortality rate of from 25 to 40 per cent, increasing with age. In this age group, particularly, the severity of symptoms must be weighed carefully before incurring the risks of surgery. Elective operations must be deferred until the patient's general condition has been brought to its optimum.

The incidence of stoneless cases (38 per cent) is high, and these cases showed a mortality rate of 9 per cent. No case of acute cholecystitis occurred in a stoneless gall bladder. Perhaps this aithic group should be considered mainly a medical problem.

Operations of choice should reflect a low mortality rate. Such operations in our series did not

By taking the following steps the mortality rate in this hospital has been lowered from 12.2 per cent in 1924 to 6.5 per cent in 1933

The indications for operation must be specific stones and a history of colic or of extra-hepatic jaundice are the more important. A clinical history of colic plus positive cholecystograms is always an indication. In the absence of a history of colic, a cholecystogram which shows poor filling and emptying should be repeated. If such findings recur, medical treatment is indicated. If this fails to bring improvement in gall-bladder function, surgery is indicated.

The preoperative evaluation of cardiac, hepatic and renal function must be thorough. The preoperative care must be sufficient to

bring the patient to the optimum condition possible.

The operative procedures must be simple, gentle and not unduly prolonged.

The anesthesia and postoperative care must be planned to reduce pulmonary complications.

In acute conditions of the gall bladder, operation must not be delayed until complications resulting from gangrene and perforation have developed. Acute cholecystitis should be considered from its onset a surgical disease requiring very close observation.

FAILURE OF NICOTINIC ACID IN THE TREATMENT OF ANEMIA

OSCAR C. HANSEN-PRUSS, M.D.*

DURHAM, NORTH CAROLINA

NICOTINIC acid and nicotinic acid amide have been isolated from liver^{1, 2} and have been used successfully in the treatment of experimental, canine black tongue^{2, 3} and of human pellagra^{4, 5, 6}. Since this drug may well be used extensively as a therapeutic agent in pellagra and perhaps in other deficiency states, it has seemed advisable to observe its effects in various types of anemia. In this paper will be reported the essentially negative effect of nicotinic acid (Eastman) when administered parenterally to 7 patients: 3 with pernicious anemia, 1 with hyperchromic anemia and liver disease, 1 with idiopathic hypochromic anemia and 2 with myeloid leukemia.

In experimental work on canine black tongue it was found that the results obtained from the injection of 1 mg. of nicotinic acid per kilogram of body weight daily for ten days were comparable with the best results obtained by the use of liver.⁸ Each of our 7 patients was given 60 mg. of nicotinic acid daily, by intramuscular or by intravenous injection. In 2 cases an evanescent flushing and subjective feeling of warmth followed the first of several injections. No other reactions were observed. In addition to frequent peripheral blood counts, cell counts were done directly on material aspirated from the sternal bone marrow. The ma-

terial withdrawn was kept from clotting by the addition of suitable amounts of crystalline potassium oxalate.

Case 1 A white female, 42 years of age, was admitted with the diagnosis of pernicious anemia and subacute combined degeneration of the spinal cord. Symptoms began 7 years before entry.

The blood showed a red-cell count of 2,500,000 with a hemoglobin of 67.7 (10.5 gm.) per cent. The color index was 1.35, and the MCV 122.5 μ^3 . The white-cell count was 5320 with 66 per cent polymorphonuclears, 1 per cent large lymphocytes, 26 per cent small lymphocytes, 4 per cent eosinophils, 1 per cent basophils and 2 per cent monocytes.

A stained smear revealed anisocytosis and poikilocytosis, with a predominance of macrocytic red cells. No immature cells were seen. The bone marrow picture as revealed by several sternal punctures was characteristic of that seen in pernicious anemia; the white-cell count was 50,000, with 1.5 per cent reticulocytes, all macrocytic. Blood Wassermann and Kahn tests were negative. Gastric analysis showed no free hydrochloric acid after stimulation with 5 mg. of histamine. On lumbar puncture the spinal fluid was clear and the pressure normal. The cell count, Pandy reaction, benzidine test and spinal fluid Wassermann were all negative. X-ray studies of the chest and abdomen revealed nothing of note.

The daily intramuscular injection of 60 mg. of nicotinic acid for 10 days had no significant effect on the peripheral blood (Chart 1), but parenteral liver therapy had a subsequent positive effect. The patient became progressively weaker and the neurologic changes more pronounced. After 1 week of treatment with nicotinic acid, the bone-marrow white-cell count had fallen to 17,000. This relatively low count persisted for 10 days after the nicotinic

From the Department of Medicine, Duke University School of Medicine, Durham, North Carolina.

*Associate professor of medicine, Duke University School of Medicine; chief medical consultant in syphilis and allergy clinics, Duke Hospital.

The blood showed a red-cell count of 4,500,000 with a hemoglobin of 85 (13.2 gm) per cent. The color index was 0.95, the MCHC 29.6 $\times 10^{-12}$ gm., and the MCV 85.5 μ^3 . The white-cell count was 200,000 with 35 per cent segmented polymorphonuclears, 32 per cent "staff" polymorphonuclears, 9 per cent juvenile polymorphonuclears, 1 per cent eosinophils, 18 per cent neutrophilic myelocytes, 1 per cent myeloblasts, 1 per cent large lymphocytes, 2 per cent small lymphocytes and 1 per cent monocytes. There were no immature red cells. Reticulocytes were estimated at less than 1 per cent. The basal metabolic rate was $\pm 1\%$ per cent.

The daily intravenous injection of 60 mg of nicotinic acid for 8 days caused no change in the white-cell count and no appreciable change in the differential white-cell formula or the hemoglobin or red-cell levels.

DISCUSSION

Although it seems well established that nicotinic acid contains a growth-promoting factor, and perhaps the pellagra-preventing factor of Goldberger, it had no antianemic value whatsoever in the instances cited here. The only hematologic change observed was a temporary depression of myeloid function, as indicated by a drop in the bone-marrow white-cell count. This fall was not mirrored in the white count or in the Schilling hemogram of the peripheral blood. On the other hand, it has been observed¹⁰ that in rats on diets deficient in the vitamin B complex, the addition of nicotinic acid will prevent the development of a nutritional pancytopenia. Nicotinic acid apparently had no effect on the platelet count. Thrombopenia in the

cases of Addison-Biermer anemia, when present, persisted until the institution of liver treatment.

SUMMARY

Nicotinic acid, in dosages known to be clinically effective in pellagra, was used in 3 cases of Addison-Biermer anemia, 1 case of hyperchromic anemia and liver disease, 1 case of idiopathic hypochromic anemia, and 2 cases of myeloid leukemia.

In such amounts nicotinic acid had no effect on the anemia or clinical course of any of these patients.

The injection of nicotinic acid was followed in each instance by a fall in the bone-marrow white-cell count.

NEW HAMPSHIRE MEDICAL SOCIETY

PROCEEDINGS OF THE
ONE HUNDRED AND FORTY-SEVENTH ANNIVERSARY

HOUSE OF DELEGATES

MAY 16, 17 AND 18, 1938

THE House of Delegates convened at the Hotel Carpenter, Manchester, on Monday evening, May 16, 1938, at seven-thirty o'clock, with Speaker Richard W. Robinson, of Laconia, presiding.

The following members answered the roll call

The President, ex-officio
The Vice-President, ex-officio
The Secretary-Treasurer, ex-officio
Chester L. Smart, Laconia
A. Philip LaFrance, Laconia
William J. Paul Dye, Wolfeboro
Francis J. C. Dube, Center Ossipee
Osmon H. Hubbard, Keene
Norris H. Robertson, Keene
William M. Bronson, Lancaster
Edgar J. Thibodeau, Berlin
Robert M. Deming, Glencliff
Leslie K. Sycamore, Hanover
Deering G. Smith, Nashua
Clarence E. Dunbar, Manchester
George V. Fiske, Manchester
Luther A. March, Nashua
Herbert B. Messenger, Franklin
Warren H. Butterfield, Concord
Oscar B. Gilbert, Exeter
Fred Fernald, Nottingham
Edna Walck, Dover
Henry C. Sanders, Jr., Claremont
Addison Roe, Newport
George C. Wilkins, Manchester
Henry O. Smith, Hudson
Robert O. Blood, Concord
Emery M. Fitch, Claremont
Frederic P. Lord, Hanover

SPEAKER ROBINSON The first order of business is the reading of the minutes of the last meeting.

DR. DUBE I move that the reading of the minutes of the last meeting be omitted.

This motion was seconded and was carried.

SPEAKER ROBINSON The next business is the appointment of a Committee on Credentials. I appoint Chester L. Smart, Francis J. C. Dube, Edgar J. Thibodeau and Clarence E. Dunbar.

The Committee on Officers' Reports was appointed prior to this meeting, with Herbert B.

Messenger as chairman and Deering G. Smith and Fred Fernald as members, the Committee on Memorials and Communications with William J. Paul Dye as chairman and Edna Walck and Clarence E. Dunbar as members.

For the Committee on Nominations, I now appoint Leslie K. Sycamore as chairman and Henry C. Sanders, Jr., Wendell P. Clare, Charles H. Cutler and Osmon H. Hubbard as members.

We are going to interrupt the regular order of business at this time in order to introduce Mr. Smith, superintendent of the Mary Hitchcock Hospital, and Miss Mary L. Whittaker of the Margaret Pillsbury Hospital, who will talk to us about group hospitalization insurance.

MR. SMITH Group hospitalization is very much of a baby, being only about four years old. It was begun in Dallas, Texas, and it gradually spread through the Middle West, and to the East Coast, and last year saw the formation of the Massachusetts group.

At one time, it was thought that we might have the Massachusetts plan extend up through northern New England. The Massachusetts plan and the New York plan are not operated by the hospitals but by men interested in hospitals, who have given money as a financial back-log to tide them over the first two or three years, when claims usually exceed the premiums.

Another plan is the formation of a company by interested individuals, which would be financially backed, so far as claims are concerned, by an insurance company. This latter plan seems, in many respects, to be more satisfactory.

We should like to know what the reaction of the medical association of this state is regarding group hospitalization. It is a big problem and one that depends for its success on the medical profession.

SPEAKER ROBINSON The meeting is now open for questions.

SECRETARY MFTCALF If this is backed by an insurance company, is there any assurance that the rate will not be raised?

MR. SMITH Only to this effect the plan itself has been incorporated by two individuals as the

New Hampshire Hospital Plan The State laws require that 79 per cent of all income must be set up as a reserve to pay possible claims. If the claims are greater than that, there might be a raise. If the claims are less, that percentage has to stay in a reserve, which is under the supervision of the State Insurance Commissioner. The insurance company acts merely as an underwriting agency. The plan will be administered, as we get the story from Mr. Kendall and Mr. Glines, with an advisory committee composed of representatives from the medical group, from the hospital group and from the lay group.

SECRETARY METCALF How soon would you like to start it?

MR. SMITH We are willing to take our time and be sure it is correct. These two gentlemen are very anxious to get it started. The hospitals are more interested in starting something that will be of greater value ten years from now than it will be, let us say, three years from now.

SPEAKER ROBINSON Miss Whittaker, would you like to speak on this subject?

MISS WHITTAKER I have nothing to add to what Mr. Smith has told you, other than that we have negotiated for the past month with the Vermont Accident Insurance Company. Their representative, Mr. Glines, could present the program which they have to offer, if you desire to have him do so.

SECRETARY METCALF Mr. Glines, will you tell us, briefly, what you told me the other day in my office?

MR. GEORGE B. GLINES Our first approach, after outlining the plan, was to contact the State Insurance Department in order to find out if such a plan could be adopted for New Hampshire. We found that the New Hampshire laws interpret hospitalization as a form of insurance and the Attorney-General has ruled that it must come under the State Insurance Department and that a non-profit plan, so-called, could not be organized in New Hampshire under our present laws.

I have a copy of the policy here. The items are as follows:

1 Each eligible subscriber is entitled to receive hospital care for a total of not more than twenty-one days on one or more admissions during the first contract year. After having been a subscriber for twelve months, he will be entitled to receive hospital care for not more than thirty days during the contract year. Hospital care shall be rendered to the subscriber upon the recommendation of a

physician. He must be a licensed practitioner of medicine and acceptable to the hospital selected.

2 In the event of an accident or other emergency requiring hospitalization at a hospital outside of New Hampshire, members are entitled to receive a credit of six dollars per day against the usual hospital charges. Should a subscriber elect to receive hospital care provided at a New Hampshire hospital which is not a member of the Hospital Service of New Hampshire, he shall be entitled to receive benefits of five dollars per day, subject to all agreements and exclusions therein contained.

3 Hospital care includes board in a semi-private room and care for twenty-one days, on one or more admissions, use of operating and delivery room, cost of anesthesia to a maximum of ten dollars, ordinary medications and dressings, routine laboratory and pathological service, and general nursing service. Obstetric care shall include any condition resulting from pregnancy, the care of the mother and the ordinary nursing care of the newborn child.

4 The agreement does not include hospital care for the treatment of any ailment of which the subscriber had knowledge at the time the subscription application was completed, pulmonary tuberculosis, after diagnosis as such, venereal disease, nervous and mental diseases, workmen's compensation cases, quarantinable diseases, alcohol or drug addiction. Hospital care arising from pregnancies is not covered until husband and wife have been subscribers for ten consecutive months preceding the culmination of pregnancy.

5 The agreement does not cover services or fees of physicians, surgeons or special nurses or their board, nor does it cover payment of x-ray diagnosis or other special services provided by the hospital.

6 Hospital care beyond the twenty-one-day period will be furnished by member hospitals at a discount of twenty per cent, not to exceed a twenty-eight-day period in any one contract year. Should a member desire more expensive accommodations, a credit of \$5.00 per day toward such accommodations shall be allowed.

This is all under the jurisdiction of the State Insurance Department, as I stated before.

There are some provisions here which are the standard provisions required by law for this type of insurance.

One of the usual provisions in a similar policy would be to the effect that all indemnities are payable to the insured, but that would defeat the purpose of this plan, which is that hospitals may be assured of their money. So, after several con-

ferences with the State Insurance Department and the Attorney-General's Office, we were permitted to accomplish a change. All indemnities in this policy are payable to the member hospital furnishing care. The Attorney-General, under the law, is permitted to allow such a change, if it works out to the benefit of the insured person, because the insured person is to receive a 20 per cent discount after the period of hospitalization which is covered under the contract is exhausted, he has ruled that the change does work out to the benefit of the insured person. It has also been approved by the State Insurance Department.

There is a paragraph in the contract, also, which states that the subscriber consents that a diagnosis of a physician and a medical record of the subscriber's hospitalization may be furnished to and used by the company for statistical, actuarial and other legitimate purposes.

Another clause specifies that all benefits of the policy shall cease at the time the subscriber is notified by the attending physician that hospitalization is no longer necessary and that the subscriber shall be responsible to the hospital for payment of all charges incurred after date of such notice.

The next clause states that the subscriber making application for hospitalization insurance does not anticipate that he or his family, at the time of the making-out of the application, is in need of hospital care. Such a clause is necessary, because no medical examination is required.

This is a group policy and will only be issued in groups of a minimum of five, or larger groups, if possible. We intend first to contact the employer for groups. If the plan meets with his approval, we shall make an attempt to form the first group in the organization. It may be a large organization or a small one. But the first group would be instituted by securing office employees and heads of departments. After we have an entree into the plant, we can leave circulars with the employer to be distributed among the employees. The circular will outline the coverage under the contract, and the cost to the insured person.

An employed person is the person who must apply, that employed person may be a man or a woman. The first person taking out the insurance—the employed person—must pay ten dollars a year, the second person in that family may be insured for eight dollars additional, and the other members of that person's family, up to nineteen years of age, may be insured for six dollars each, regardless of number.

There is a fifty-cent subscription fee for the first application, and there is no other fee for the

other members of the family, outside of the amounts I have just given you.

SPEAKER ROBINSON This does not include any x-ray work done in the hospital?

MR GLINES No.

SPEAKER ROBINSON How about blood transfusions?

MR. GLINES They would not come under this contract.

These provisions have been drawn up in cooperation with the President of the State Association of Nursing Superintendents and the hospital superintendents, and Mr. Smith, of the Mary Hitchcock Hospital in Hanover, has made an intensive study of all the plans which are in effect today. This plan is the result of several conferences.

DR DUBE By groups of five, do you mean these people have to be employed by a certain person? Suppose, in a small town, there were five different individuals who wished to subscribe.

MR GLINES We believe that a situation of this sort can be handled very nicely. Let us take an illustration. An office organization has a potential group, but all members might not wish to come in right away. We will put the applications on file. When we have a group of five, we shall then issue a group certificate to each one.

MR SMITH I think what the doctor meant was this. If you have an office where three people want to join, how about the other two members needed to make up the group of five?

MR GLINES In that case, I believe we shall find that there may be two or three stores or employers engaged in practically the same line of business, and we could combine those under one group. Then we should have a group of five and probably more.

With reference to the farmer and his group, they all have their state organizations, and many of them are members of either the Grange or the Farm Bureau. We should approach those people through the head of their organization.

DR DUBE I meant by my question, suppose five people of different groups wished to have the benefits of such a policy. Let us suppose that a doctor, a lawyer, an oil man and a garage man wanted to get together and make a group of their own. What then?

MR GLINES I do not see any objection to that, if that is the only way to handle the matter. But

I think the most acceptable way would be to combine classifications in one group, rather than several different classifications of employment in the same group

DR. DYE Suppose you have an individual family under five members who want this type of policy What then?

MR. GLINES The first member of the family to apply must be the employed member, the second would be the husband or wife, and that would be the eight dollars additional charge, and then to include all other members of the family, regardless of the number, up to nineteen years of age, it would cost six dollars each

DR. DYE Is it essential that the head of the family be employed? Suppose the head of the family is retired

MR. GLINES There would be no objection to that But the fundamental reason for the issuance of these group policies is to make them within the reach of the average man, and handled on a payroll deduction basis, so it is easy to make payments, if the payments were to be made quarterly or semi-annually or annually, there would be more of a chance to omit payments

We do not intend to commercialize this plan in any way, through commissioned agents All the field work and soliciting, if you call it soliciting, will be done by salaried men under our own supervision, so that we shall have control of them at all times, and can direct their activities along the lines we feel most advisable We do not plan to use high pressure It is merely our idea to inform people of the fact that the plan is available and within their reach, through a payroll deduction

We use a master card for each employer, and file it under the town or the industry of the employer, then, as additional groups are formed, they can come in at any time In most cases, such groups will be on a monthly deduction basis

QUESTION Is this contract cancelable?

MR. GLINES If the subscribers do not continue their payments, they are automatically dropped from the list If such a person comes in again, he would have issued to him a new certificate, with the fifty-cent enrollment fee We hope to have very few cancelations

QUESTION Can the insurance company cancel a man's policy?

MR. GLINES No, we have no reason to cancel We could, I suppose, under the law

QUESTION What if they elect to go out of the State for their hospitalization?

MR. GLINES The contract is so drawn that it favors New Hampshire hospitalization above all others One gets much better hospitalization in New Hampshire than he could get in any other State

DR. D. G. SMITH This covers the anesthesia, but does it cover the services of the physician?

MR. GLINES No We do not pay any doctors' fees We allow ten dollars to the member hospital for anesthesia

MR. SMITH We have attempted all the time to keep physicians' fees out of it, both in the x-ray departments and the medical laboratory departments, as well as anesthesia and everything else We have attempted to make it in accordance with the suggestion of the American Medical Association It does not include any physicians' fees of any kind

DR. SANDERS I move that this matter of group hospitalization insurance be referred to the Committee on Memorials and Communications

This motion was duly seconded

MR. GLINES May I say just one more word We should like to organize and, through you doctors, obtain two members for an advisory board In other words, we should like two members from the State Hospital Association, two from the New Hampshire Medical Society, and two public-spirited men, so that we may get the best plan possible and have it work effectively

The motion was unanimously carried

SPEAKER ROBINSON The next order of business is the report of the Secretary-Treasurer

The society is in good financial condition with all debts paid and a balance of nearly a \$1000 in the bank. The Benevolence Fund on December 31, 1937, amounted to \$1701.24. During the past year we received from the Women's Auxiliaries \$40.00 for this fund.

No officers of the society have died during the past year. Among the members whom we lost was Dr. Mary S. Danforth, of Manchester, said to be the oldest woman physician in New England. Dr. Danforth received the fifty year medal from this society in 1928.

For the two appointive offices which lie within the province of your president, Dr. Ladd chose these men for anniversary chairman, Chester F. McGill, of Portsmouth, and for member of the New England Medical Council, Harry O. Chesley, of Dover.

I can report as follows concerning the recommendations which were made by the House of Delegates last year.

1. The so-called Vermont plan of malpractice insurance was studied by a subcommittee of the Advisory Committee on Jurisprudence, this subcommittee feels that it is inexpedient to adopt the Vermont plan at the present time.

2. A check for one hundred dollars was sent to Mr. Frank J. Sulloway in return for his work with the Advisory Committee on Jurisprudence and for the free consultation that he has made available to every member of the society. From the wording of the resolution concerning this fee at last year's meeting of the House of Delegates, I assume that a similar sum should be sent to Mr. Sulloway annually until further notice.

3. Your secretary sent to the Surgeon General of the Public Health Service a letter expressing the desire of this society to co-operate in the attempt to eliminate tropical diseases. The Committee on Public Relations of

ferred its services to the State Board of Health for this same purpose.

4 The Committee on Mental and Social Hygiene has been asked to render a report at this time in regard to simpler methods of procedure for the sterilization of mentally deficient persons. This same committee has been asked to report also on the desirability of changing the method of commitment to the New Hampshire State Hospital.

5 Your secretary brought to the attention of the several county secretaries a recommendation that the President of the Society be asked to visit each county society and a further recommendation that it might be desirable to make the county secretaries members of the House of Delegates. Because of these two recommendations, the President of the Society has had numerous invitations and we now have in the House of Delegates seven of the ten county secretaries.

6 The chairman of the Committee on Medical Education and Hospitals was asked to prepare a revised list of the Speakers Bureau and to furnish copies of this list to the several county secretaries.

7 Two important bills which received the approval of this House of Delegates were passed at the most recent session of the State Legislature. The first bill requires the presentation of a negative blood test for syphilis before the issuance of a marriage license. This bill takes effect on October 1, 1938. The second bill requires that all physicians establishing practice in New Hampshire shall have at least one year's internship approved by the Board of Registration in Medicine. A third important bill, which was passed but which did not come officially before this House of Delegates, requires that a suit for malpractice must now be brought within two years of the alleged offense.

8 The State Board of Health was notified that this society believed that approval should not be given to lying-in hospitals unless they met certain requirements enumerated by the Committee on Maternity and Infancy.

9 The State Board of Health was further advised that the House of Delegates approved the pneumonia program which is in effect in Massachusetts and hoped that a similar program could be inaugurated in New Hampshire. This step has now been taken. Free pneumonia serum is available for persons afflicted with this disease and arrangements are being made to provide the necessary laboratory facilities in various parts of the State. A short reel, illustrating the use of pneumonia serum, has been shown in moving picture houses.

10 The question of group hospitalization was referred to the Hospital Superintendents Club.

The work of some of our more important committees deserves mention.

The Publication Committee has again had its troubles. Addresses at the annual meeting which are given extemporaneously are not suitable for the *New England Journal of Medicine* and it is often difficult to get the speaker to write his address in simplified language. The net result is that two addresses which were given at our meeting in 1937 did not appear in the *Transactions*. The column "Miscellany" which for two or three years has been printed in the *New England Journal of Medicine* is now being edited, not by your secretary, but by Dr. Fred E. Clow, of Wolfeboro. You have no doubt noticed the improvement.

The Advisory Committee on Jurisprudence has held three or four meetings this year. All prospective or actual suits against members who are insured in the Hart-

ford Accident and Indemnity Company are now referred directly and immediately to Mr. Sulloway. Such suits are being handled expeditiously and are being reviewed promptly by the committee, in fact there are no suits now pending which the committee has not considered. The number of suits has decreased. It is possible that the Hartford Company will be able to offer a lower premium rate.

An attempt was made this year to hold a meeting of the New England Medical Council to consider the present social trend of medical practice. Massachusetts gave a lukewarm approval of such a meeting, but all the other New England States refused to attend. It seems to me an idle gesture for us to appoint annually a group of men for a council which presumably will never meet.

When the appointment of a Committee on Medical Economics was considered a few years ago, Dr. Henry O. Smith, of Hudson, said that such a committee was unnecessary and that its function could be performed better by the Committee on Public Relations. At that time I demurred but believe now that Dr. Smith was right. The Committee on Medical Economics is not and cannot be in sufficiently close touch with the Secretary and the Committee on Public Relations to co-operate successfully. If it is not going to hurt someone's feelings I recommend that the Committee on Medical Economics be discontinued.

In a few instances during the past year I have been distressed by the medical testimony in tort cases because it has been palpably inaccurate. A few years ago a doctor from a neighboring state came to New Hampshire to give inaccurate testimony of this sort. I reported the matter to the Committee on Ethics of the medical society in this neighboring state and this committee issued the following decision about the offending doctor: "His testimony is unethical, unprofessional, prejudiced and discourteous, and does not state facts as they are. It is an attempt of one trying to give expert testimony who is not qualified to do so, and it must appear that it was given simply for a fee, rather than from a sense of duty, against one of our profession in trouble. These words are harsh but the offending doctor has not again given testimony against one of his fellow practitioners."

I do not know whether we ought to have a Committee on Ethics in New Hampshire, but I do believe that a hard-boiled critic would increase the accuracy of some of the medical testimony that is heard in court.

Meanwhile, the attempted socialization of medicine goes on apace. Verily, we are headed for the government ownership of medicine in a hick.

CARLETON R. METCALF

SPEAKER ROBINSON: Dr. Messinger, are you ready with your report on the Secretary-Treasurer's report?

DR. MESSINGER: The Committee on Officers' Reports wishes to thank the various officers and chairmen of committees for the promptness of their reports, and the concise manner of their presentations.

We recommend the acceptance of these reports and their incorporation in the transactions of this society.

I move that that portion of the report of the Committee on Officers' Reports be accepted.

This motion was seconded and was carried.

DR MESSINGER This Committee recommends that Frank J Sulloway be sent a check for one hundred dollars each year, until further notice I so move

This motion was seconded and was carried

DR MESSINGER The Committee on Officers' Reports recommends that the Committee on Mental and Social Hygiene be asked to study the methods of procedure for sterilization of the mentally deficient persons with simplification of the procedure in mind A consultation with Frank J Sulloway on the legal aspects of this procedure would be well worth while

In view of the present medical and economic unrest, the committee recommends the continuance of the Committee on Medical Economics

I move that this portion of the Committee on Officers' Reports be accepted

This motion was seconded and was carried

DR MESSINGER This Committee believes that no Committee on Ethics is necessary, but that unethical practices should be brought to the attention of councilors

DR D G SMITH I move that that portion of the Committee on Officers' Reports be accepted

This motion was seconded and was carried

SPEAKER ROBINSON The next order of business is the councilor's report for Sullivan County

Councilor's Report for Sullivan County

The Sullivan County Medical Society has enjoyed its usual healthy condition during the past year The membership for 1937 was 100 per cent and the interest enthusiastic

The annual meeting, which was held in Claremont on November 18, was the only meeting during the year However, this was unusual in scope as it took place on the same day as the annual round up of the Claremont Diagnostic Cancer Clinic and at the morning session we had a review of many of the cases seen during the year

Pathologists from the State Laboratory were present to do frozen sections on biopsies taken from suspicious cases, thus correlating the clinical examination with the pathological findings We were favored by the presence of Samuel T Ladd, of Portsmouth, president of the New Hampshire Medical Society

Luncheon was served at the Claremont Hospital The afternoon program consisted of a very interesting talk on brain surgery by Elliott C Cutler, chief surgeon of the Peter Bent Brigham Hospital, of Boston

Immediately after the scientific paper, there was an informal debate on medical economics, built around the activities of the 'Committee of 430, between Dr Cutler on the one side and President Ladd on the other This was hot. Possibly the real issues which made the

discussion a draw were 6 00 p m. and a telegram from Boston for Dr Cutler to hurry back to a case. At any rate, I think the decision of the Sullivan County Medical Society is that we are not quite ready for state medicine.

There were a large number of visiting doctors present from outside the county, including some from Massachusetts and Vermont. We all had a wonderful day and are deeply indebted to Dr Cutler, Dr Ladd and Dr. Kingsford for their share in the program

EMERY M FITCH, *Councilor*

SPEAKER ROBINSON The report will be turned over to the Committee on Officers' Reports for its consideration Are there any other councilors' reports that anyone has at this time? If not, we will go on to the reports of standing committees

Report of Committee on Control of Cancer

The chief activity of your committee during the past year has been the preparation and distribution of three letters to the medical profession in New Hampshire. These letters describe briefly important phases of some aspects of cancer control

The first one, issued in December, 1937, was entitled 'Cancer of the Uterus' The second one, issued in February, 1938, covered the subject of 'The Proper Handling of Biopsies,' and the third one, issued in March, 1938, suggested methods by which the presence of cancer could be detected during routine physical examinations

The committee feels that these rules laid down to guide the physician in the examination of a patient for the detection of possible cancer are extremely important

At the request of physicians interested in cancer education, the committee has sent copies of present and past letters, together with the handbook *The Early Signs and Symptoms of Cancer* to New York, Georgia, Connecticut and Vermont.

The committee stands ready at all times to co-operate with the New Hampshire Cancer Commission, with its cancer clinics, and with the hospitals of the State and with the American Society for the Control of Cancer The activities of the Women's Field Army, sponsored by the American Society for the Control of Cancer, receive our heartiest support.

New Hampshire was chosen as the first state to be organized early in 1937, and this year there are forty-five states actively engaged in this campaign for membership during the month of April Last year many members of the New Hampshire Medical Society assisted this activity by speaking on cancer to seventy three groups in the State.

Cancer is our second cause of death in the country, and New Hampshire has the highest cancer mortality rate in the United States Every physician should feel his responsibility toward controlling this disease by educating his friends and patients in the knowledge that cancer is a curable disease, but that its curability depends upon early recognition and early treatment.

By means of talks given by physicians, by a changed attitude of the public in its relation to the discussion of cancer, and by the distribution of large amounts of informative literature to most of the homes in the State, the citizens of the State are acquiring a much needed education regarding cancer and its control

It behooves every physician to keep himself well informed of the fundamental principles of cancer diagnosis in order that he may detect the signs that might indicate

the presence of cancer. It should always be borne in mind that the fate of the cancer patient rests with the physician who is first consulted.

From information obtained from the personnel of the State Cancer Clinics, there still appears to be an unfortunate lack of appreciation on the part of some physicians of the serious implication of certain sores in the mouth, rectal bleeding, hematuria, and flowing between periods and after the menopause.

Your committee has expended, due to the increased mailing costs demanded by the larger membership, the entire amount appropriated for its use. We ask for an appropriation of sixty dollars for the ensuing year.

GEORGE C. WILKINS, *Chairman*
HOWARD N. KINGSFORD,
GEORGE F. DWINELL, *Secretary*

SPEAKER ROBINSON: This report has already been considered by the Committee on Officers' Reports.

DR. MESSINGER: The Committee on Officers' Reports heartily approves of the pamphlets distributed.

We recommend the appropriation of sixty dollars for this committee's work.

I move that this portion of the report be accepted.

This motion was seconded and was carried.

Report of Committee on Medical Economics

In regard to an unofficial fee schedule for workmen's compensation cases, your committee has made an investigation as asked by the House of Delegates. It finds that there seems to be a varying amount of interest in such schedules by insurance companies. Some companies say that they manage satisfactorily without such lists; others believe they would find them of value as an indication to the physician of a reasonable charge for his services.

In respect to hospitalization insurance, the House will recall that three years ago this matter was placed in the hands of the Hospital Superintendents' Club. It is learned from this group that the subject is of real interest to that body and that it would like to see such a system set up.

The rural nature of this state, the lack of many large industrial centers, the great amount of present and past unemployment, the differences found in various districts, all make it extremely difficult to find a system which would fit the entire state, while small regions present the difficulty of possessing groups too small to be suitable for such insurance with financial safety in cases of epidemic or widespread sickness. The possibility of joining an already existing group for such insurance in another state and that of taking out such insurance in a commercial company — and these are rapidly coming into being — may prove more practicable in achieving hospitalization insurance.

Shall the Committee on Medical Economics be continued? This is a matter naturally for the House of Delegates to settle. It might not be amiss for this committee to make some comments on the subject, after three years of existence. The large questions concerning socialization of medicine the committee has not officially considered. This is due in part to the magnitude and difficulties of this fundamental subject, and a hesitation to embark upon this line when differences throughout the country

among members of our own profession are so profound and involve so much heat, and in part to the field to be covered by this committee.

The question of jurisdiction was brought up at the time this committee was created and was never settled by the House. It is a logical assumption that this task should belong to the Committee on Public Relations. Among its membership of five, it includes the three outstanding elected officers of the Society — the President, the Vice-President and the Secretary-Treasurer, as ex-officio members. It might well seem that to that committee would belong a question of so much importance to this society, rather than to the Committee on Medical Economics. If so, there would seem to be little reason for continuing the latter committee longer.

Another solution would be to make the Committee on Medical Economics an adjunct to the Committee on Public Relations, and the latter might call upon the former for special study and advice, if and when desired.

If the Committee on Medical Economics is to be continued, it would seem advisable that the field of this committee should be more definitely stated. I might add that the members of this present committee are not in agreement in this respect.

TIMOTHY F. ROCK,
LESLIE K. SYCAMORE,
FREDERIC P. LORD, *Chairman*

Report of Committee on Medical Education and Hospitals

The activities of this committee during the past year have been concerned with the continuation of the program of the Commonwealth Fund relative to postgraduate studies, with further increase in the Speakers' Bureau, and with consideration of the question of the necessity or desirability of promoting a basic science law in this state.

Commonwealth Fund Fellowships. The purpose of the Commonwealth Fund fellowships has been explained in previous reports. The same offer is continued this year by the Commonwealth Fund, and on January 31, 1938, an announcement was sent out to the members of the Society along with a letter from Dr. Ladd, our president. To date we have received eighteen requests for application forms, which are filled out by the applicant himself and mailed by him to the office of the Commonwealth Fund in New York City. At this time last year there were twenty-two requests for applications.

We have discussed with the officials of the Commonwealth Fund the fact that the percentage eligible in this state is rendered too low by virtue of their primary requirements, which are (1) that the applicant be established in practice in his locality for not less than five years, (2) that he be not over forty years of age, (3) that he be in practice in a community of less than 10,000 population. As we have reported before, the percentage of men in this state who could qualify is very small.

The fellowship awards made in 1937 were as follows:

Phillips, Arthur F., Bristol — Medicine
Turley, Raymond J., Meredith — Medicine
Jacques, Laura G., Tilton — Medicine
Eastman, Cyrus D., Monroe — Medicine
Hazen, Harris B., Lebanon — Medicine
Huse, Ernest L., Meriden — Medicine
Reische, Merrill G., Meredith — Medicine
Copenhaver, Leslie B., North Woodstock — Medicine
Churchill, Kenneth, Lebanon — Medicine

Doyle, Peter J., Dover — Obstetrics
 Eckels, John C., Lisbon — Obstetrics
 Levine, Harold D., Bristol — Obstetrics
 Beattie, Barbara, Littleton — Pediatrics
 Johnston, Albert C., Gorham — Roentgenology
 (3 months)

It is interesting to note that during the past year there has been increased activity on the part of the Federal Government in the field of postgraduate medical instruction. Possibly an offspring of the same movement is the appointment of a full time man by the American Medical Association to co-operate, in an advisory capacity, with the state societies relative to the program of graduate instruction.

Speakers' Bureau At the time of the circularizing of the membership of the Society in January, in connection with the Commonwealth Fund fellowships, requests were included for amplification of the listing of the Speakers' Bureau. Fourteen names were added at this time, and the list has been placed in the hands of the secretary of each county society. It is difficult to obtain information as to how extensively this listing is used in obtaining speakers for county meetings.

The Basic Science Law At the meeting of the House of Delegates in May, 1937, it was voted to ask the Committee on Education and Hospitals to consider the necessity and desirability of promoting a basic science law in this state, and to report on this matter at the annual meeting of the House of Delegates in 1938.

For information and material on this question, your committee has contacted the American Medical Association and the Minnesota State Board of Medical Examiners. The latter state has been one of the pioneers in the field of the basic science law.

In general the basic science law has been adopted as a public-health measure aimed at the elimination of the poorly trained and equipped individual of whatever school of practice. Its administration is under the control of a separate board which conducts examinations in the basic medical sciences, and whose certification is necessary for eligibility for examination for a license to practice.

It has, therefore, resulted in the existence of two state boards and of two fees to be paid by the applicant. This has resulted in some difficulty and some ill feeling in the field of interstate reciprocity, because the only exemption from the Basic Science Board examinations, where non-existent in the other state, is provided by the certificate as a diplomate of the National Board.

A further difficulty lies in the fact that with the introduction of a Basic Science Board, there has resulted usually a board of mixed membership consisting of medical men, representatives of osteopaths, chiropractors, and so forth.

It is the feeling of your committee that the question is not subject to definite recommendation at this time and that it be considered further by this Committee in co-operation with the Committee on Public Relations and the State Board of Medical Examiners.

It is our belief at this time that the introduction of the basic science law in New Hampshire would add little to the control by the State Board of Medical Examiners and that it would probably lead to more difficulty than it would alleviate.

In connection with this study, it has been made rather apparent that one of the real needs of the State of New Hampshire is an annual registration law which would

considerably reinforce the controlling powers of the State Board of Medical Examiners.

JOHN P. BOWLER, *Chairman*,
 JAMES W. JAMESON,
 HARRIS E. POWERS

DR. MESSINGER The Committee on Officers' Reports is glad to note the increasing number of men taking advantage of the Commonwealth Fund fellowships.

We note that the Speakers' Bureau list has been revised, and we hope that the county societies will make more use of it.

We agree with the opinion that the basic science law is not feasible for this society at the present time and that it be held for further consideration.

This Committee recommends that the Committee on Medical Education and Hospitals confer with the State Board, concerning the annual registration of physicians, with the passage of such a law in view.

DR. MESSINGER I move the adoption of this portion of the report.

This motion was seconded.

DR. WALCK What would be the fee for the annual registration?

SPEAKER ROBINSON It would be two dollars, I believe.

DR. DUBE Why does the Board need to have more accurate knowledge of who is practicing by registration? Of what benefit is it going to be to them?

DR. D. G. SMITH I think it would be valuable to know whether doctors are located in the State, thereby bringing the mailing list up to date.

SECRETARY METCALF Is this annual registration vital enough to pay for the bother and expense of it?

DR. DUBE Does not the Board have a record of all the licensed physicians and of all the licenses granted, whether by reciprocity or examination?

DR. D. G. SMITH Yes.

SPEAKER ROBINSON The question is still open for discussion. The motion before the House is on the adoption of this part of the report of the Committee on Officers' Reports. Are you ready for the question?

There was an overwhelming "no" vote, and the motion was lost.

DR. MESSINGER Then I move that the first three paragraphs of our report be accepted

This motion was seconded and was carried

Report of Committee on Maternity and Infancy

During the year that has elapsed since the last meeting of the Society, this committee has held seven meetings. At these meetings we have made a study of all the information which the committee has been able to obtain on each individual maternal death. The material used consisted of a copy of the death certificate, answers to questionnaires sent to physicians and in many cases information obtained by the State Board of Health and by contacting the physicians in charge of the cases and wherever possible, by checking the hospital records.

In all cases the patient has been known to the committee only by number, the committee not knowing the location, the hospital or the physician in charge.

In 1930, the infant mortality was 61 per 1000 live births. In 1936 it was 47. In 1930, twenty three states had a higher infant mortality than New Hampshire and 26 had a lower. In 1936, thirty nine states had a higher infant mortality, seven lower and three the same. In 1936, the infant mortality rates ranged from 115 in New Mexico to 42 in Connecticut, New Hampshire was in the upper ten for low infant mortality.

In 1930, maternal mortality per 1000 live births was 6.2, in 1935 it was 6.1, and in 1936, 4.8. In 1930, twenty six states had a higher maternal mortality than New Hampshire, and in 1935 there were nineteen states.

The number of maternal deaths in 1935 was 46. In 1937 it was 32.

The neonatal mortality (deaths under two weeks) in 1930 was 37.3 per 1000 live births, and in 1935 it was 35.3.

In the causes of maternal death in 1937, the greatest number were due to (1) toxemia of pregnancy, (2) embolism, and (3) postpartum hemorrhage.

A study of stillbirths, which was made almost entirely from death certificates and answers to a questionnaire, showed that there were 181 stillbirths reported. Questionnaires were sent to 181 and answers were received from all but 14. The leading causes of death in this list were (1) deformity, (2) prematurity, (3) asphyxia, and (4) toxemia of pregnancy.

During the last session of the Legislature, at the recommendation of the committee, the Medical Practice Act was amended to require "an internship of not less than twelve months." We have an agreement with the Board of Registration in Medicine that in the case of all physicians who may practice obstetrics the internship must include a reasonable amount of obstetric training.

Under the Social Security Act, much larger appropriations have been made available for maternity and infancy work. There has recently been proposed by Dr Underwood, of Mississippi, an amendment to Title 5, Part I, of the Social Security Act to provide additional sums to carry out maternity and infancy work—during the year of 1939, \$3,000,000. 1940, \$8,000,000, 1941, \$12,000,000, 1942, \$16,000,000, 1943, \$20,000,000.

At the meeting of the committee held on March 23, 1938, it made the following recommendation which was transmitted to the State Board of Health:

That it is the opinion of the committee that as large appropriations as apparently contemplated will tend to unbalance plans of county and state departments of health by overemphasizing a single phase of public-

health work and that the use of such large appropriations to be allocated by a federal bureau will tend to produce public sentiment in favor of state-controlled medical practice.

There has been much improvement in the living in hospitals and homes, especially the latter, since our last report. Following the transfer, as recommended by your committee of the licensing of obstetric departments of hospitals and maternity homes to the Department of Health, definite requirements were drawn up as minimum standards required for licensing, and several places that did not meet the requirements from the point of view of medical care or fire hazard have been eliminated.

Statistics show that each year more than 14,000 women in the United States die from causes connected with childbirth, leaving at least 35,000 children motherless, that more than 75,000 infants are stillborn and that about 69,000 die during the first month of life.

In addition to this list of deaths, morbidity, both immediate and more or less permanent, claims an uncouneted number of mothers. During the last twenty two years, statistics show that there has been little reduction in maternal mortality. However, the death rate from toxemia has tended to decline. The mortality rate from septicemias and hemorrhage shows very little reduction.

In studying the maternal deaths this year, the committee has attempted to divide them into three groups, first, those in which the patient was at fault, secondly, those in which more efficient medical treatment was needed, thirdly, unavoidable deaths.

The committee wishes again to call your attention to previous recommendation that obstetric cases be cared for in separate departments and delivered in rooms used only for that purpose and that special rooms be provided for the isolation of all infected cases. That caps, masks and sterile gloves and gowns be worn at all deliveries and that, in the case of hospitals, special apparatus for resuscitation and combating hemorrhage be available, that the ammoniated-mercury treatment, previously recommended by this committee, or other preventive treatment be used to prevent impetigo, that cesarean sections be elective only and preferably that consultations be held on all cases before operation, that high and midforceps be eliminated so far as possible and that forceps be used only on cases when the head is on the perineum. Vaginal examinations during delivery should be replaced by rectal examinations.

We note in studying the histories of 32 cases this year that autopsies were performed on only 5 and that these cases were not obscure.

In conclusion, the committee wishes to recommend the taking of Wassermann tests on all mothers as soon as they come under treatment. Because of the inaccuracy of cord Wassermann tests done on blood from the cord, it believes that such tests should be discontinued.

We believe that it is possible to reduce materially the number of maternal deaths in New Hampshire, especially in the two largest groups—toxemias and surgical obstetrics.

We further believe that obstetrics is sufficiently important so that men who are not qualified, either by training, undergraduate or postgraduate, or who are not equipped to handle obstetrical emergencies, either themselves or with a consultant near at hand, should refer such cases to a trained obstetrician.

ROBERT O. BLOOD
BENJAMIN P. BURPEE
CHESTER F. MCGILL

DR MESSINGER We commend the meticulous work of this committee. We agree that maternal mortality should be reduced, if possible, and that the proper method of so doing is to give publicity among physicians.

I move the adoption of the report.

This motion was seconded and was carried.

Report of Committee on Mental and Social Diseases

No elaboration of the mental hygiene program for the State has been made in the past year, chiefly due to the lack of funds. The State Hospital still maintains outpatient clinics in Manchester, Nashua and Concord.

The Laconia State School has completed a well-designed hospital building for the care of its helpless and more or less crippled children.

The House of Delegates last year passed a resolution referring to this committee the matter of improving the commitment laws of this state. Your committee believes the present commitment laws are very satisfactory, with one exception, provided the requirements of the law are fully carried out. The exception is that the act passed in 1935, relative to commitment to the State Hospital, does not give the power of commitment to county commissioners, and there is no reason why they should not have the same power as selectmen.

In the field of social hygiene the State Board of Health and United States Public Health Service have won a good fight passing the law requiring blood tests on those contemplating marriage.

The control of venereal disease is carried on by the State Board of Health, as in the past, by lectures and the distribution of literature, free to the public, and through treatment rendered by clinics maintained by the Board in five cities of the State,—Berlin, Dover, Concord, Manchester and Nashua,—where free treatment may be secured.

Through federal aid, free drugs for the treatment of syphilis are furnished to all physicians asking for them and reporting cases as required by the State Board of Health.

Through the better co-operation of the physicians, a great improvement has been noted in the reporting of cases by physicians of the State during the past year.

CHARLES H. DOLLOFF
BENJAMIN W. BAKER,
CHARLES A. WEAVER

DR MESSINGER The Committee on Officers' Reports approves the recommendation that county commissioners be allowed the same power of commitment as selectmen, and that this matter be referred to the Committee on Public Relations.

I move the adoption of the report.

This motion was seconded and was carried.

Report of Committee on Tuberculosis

The past and present of the tuberculosis control program in our state and nation is known to you.

Since the beginning of the century, tuberculosis has

declined from the leading cause of death to the sixth place in the nation and to the seventh in New Hampshire. This remarkable result has been brought about through the united efforts of the people and the medical profession.

What is to be the future of the tuberculosis control program in our state and nation? Has the phenomenal reduction in the death rate reached its irreducible minimum? Will the medical profession and the people of the State continue their active interest and support of the campaign against tuberculosis?

Let us answer the last question first. As to the medical profession, the answer is apparent in the organization of tuberculosis committees by many medical societies (in the New Hampshire Medical Society since 1914), the increasing number of professional studies, the increasing activity of the profession in examining contacts, the more frequent use of the chest x ray for diagnosis and in securing necessary clinical and sanatorium facilities.

As to the people, the answer is also clearly apparent in their increasing grasp of the fundamentals of the known knowledge of the means of transmission, of prevention and of cure of the disease, their ready participation in activities for discovery of the disease (98 per cent of the children in a recent high school tuberculin test demonstration securing consents of parents for the tests), increasing willingness of patients to enter the sanatoriums, the increasing financial support given by the people to the sanatoriums for additional beds and to tuberculosis associations to expand their educational and case finding services. The profession and the public want more good tuberculosis work, more early diagnosis, more prevention, more cures and further reductions in tuberculosis death rates.

Since 1920 the tuberculosis death rate in New Hampshire has been reduced from 97 to 33 per 100,000 population. Have we reached the irreducible minimum? There was no reduction in the death rate in 1935. In 1936 there was an increase of 2 deaths over the total for the preceding year.

However, we do not believe that we have reached the irreducible minimum in the tuberculosis death rate in New Hampshire. With more and more of the 'spreaders' of the disease being constantly searched out, the foci of infection are being controlled, and consequently, decreasing numbers of people are becoming infected. With increasing effectiveness of sanatorium treatment, more patients are being cured. Through the prompt examination of contacts by means of the tuberculin test and chest x rays of positive reactors, we can detect early manifestations of the disease and bring about a cure, thus preventing future 'spreaders'. We can look forward with confidence to halving the present tuberculosis death rate within the next ten years.

Through the assistance of the New Hampshire Medical Society there has been an increase in the number of sanatorium beds. The long waiting lists of the past have been absorbed.

The use of chest surgery at the two sanatoriums is increasing with encouraging results. Last year your committee offered to assist in the interpretation of chest films. The service has developed into a sizable responsibility, and several hundreds of films have been forwarded for interpretations during the past year. Again, your committee would urge still greater use of the x ray of the chest, particularly for persons complaining of lassitude, loss of weight or hemorrhage. Many will show marked but curable tuberculosis, which on physical examination will present little or no evidence of the disease.

X rays of the chest should be taken particularly in young

adults, for the disease is most prevalent in the twenty to twenty nine year-old age group. This is already being done in the colleges and universities. However, the incidence of tuberculosis is relatively low in the college and professional groups but high among unskilled workers.

The New Hampshire Tuberculosis Association has been aided materially in its chest diagnostic service for this class of people through the participation of the hospitals of the State in providing x-rays of the chest for clinic cases at a nominal fee.

Your committee suggests that when members of the Society send in chest films to the New Hampshire State Sanatorium or to the New Hampshire Tuberculosis Association for interpretation that they enclose a brief history of the case.

May we also urge upon the members of the New Hampshire Medical Society the vital importance of repeated sputum examinations for tubercle bacilli. It is only too true that physicians and patients are sometimes lulled into a sense of false security, patients are told that they have no tuberculosis following only one sputum examination which happens to be negative.

Just at the present time the State Tuberculosis Association, in collaboration with Dr. A. L. Winograd, of Nashua, is carrying out a study relative to the reliability of the Lederle patch test—tuberculin on adhesive tape applied to bare skin—as compared with the purified protein derivative tuberculin test, intracutaneous. Already 878 children have been given both tests simultaneously. It is planned to carry on the study to a total of approximately 2000 children this spring. If the Lederle patch test proves to be as reliable as the intracutaneous test (Mantoux) it offers an effective means in private practice of sifting out those persons with tuberculous infection easily and economically, for as few as one patch test may be purchased at a time.

ROBERT B. KERR
ROBERT M. DENING
JOHN D. SPRING

DR. MESSINGER. The Committee on Officers' Reports wishes to commend the Committee on Tuberculosis for its continued fine work to reduce the death rate from tuberculosis.

The service extended gratuitously by the committee to general practitioners for reading x-ray films is an excellent service.

If the study being made at the present time of the Lederle patch test proves reliable, we hope that the committee will publish its results so that all members of the Society may become acquainted with them.

I move the adoption of that portion of the report.

This motion was seconded and was carried.

Report of Committee on Child Health

The committee has little new to report for the past year. We would again recommend a series of lecture courses in pediatrics, under the joint auspices of the Society and the State Board of Health, comparable to the series in obstetrics recently held.

We again favor having free diphtheria toxoid and small pox vaccine available to doctors for use in needy cases. This should encourage such immunizations in doctors' offices and reduce the necessity for free clinics.

There has recently come to our attention a brief summary of immunization procedures which we hope can be distributed to the members of the Society. Recent significant changes in preferred methods make such a pamphlet of considerable value.

The committee is interested in the problems of determining the number of crippled children in the State. The Board of Health needs this information in connection with plans to aid needy members of this group. When it can be determined exactly what the term "crippled child" includes, for the purposes of this work, the aid of the members of the Society may be requested to complete a register of such children. The committee feels that the Board of Health should have the full co-operation of the Society in this matter.

TRAVIS P. BURROUGHS,
FRANKLIN ROGERS,
COLIN C. STEWART, JR., *Chairman*

DR. MESSINGER. The Committee on Officers' Reports agrees with the report of the Committee on Child Health that more education in this field is needed. However, we do not believe that the physicians would attend a series of lectures. If each county society would have one lecture by some outstanding pediatrician, more physicians would attend.

We now move the appropriation of fifty dollars for pamphlets to be sent to all physicians regarding immunization procedures.

This motion was seconded and was carried.

Report of Delegate to the American Medical Association

The Atlantic City session of 1937 was even better and more largely attended than the 1935 session. Nearly ten thousand doctors were present, and the papers and exhibits were of the very best.

The House of Delegates had several extra sessions and many resolutions were adopted. Your delegate again served on the Reference Committee on Credentials. It is of interest to note the increased attendance of the New Hampshire doctors, twenty-two registering in 1937, as compared with eight in 1935.

There was created a Distinguished Service Award which provides for fitting recognition to fellows rendering distinguished service in the science and art of medicine. Contract practice was more fully defined and a Council on Industrial Health was established. It was recommended to the Social Security Board that examinations for blindness be carried out only by doctors of medicine who are competent to diagnose and treat diseases of the eye. The Council on Medical Education and Hospitals was urged to find some way to make more extended inspection of hospitals.

A resolution was passed requesting the school authorities to put the family physician's name on each child's index card, and that the physician and also the parents be informed of any accident or illness occurring in the school. It was recommended that this action be brought

to the attention of the secretaries of the state and county medical societies

To aid in the attempt to reduce automobile accidents, it was urged that the legislative committee of the various state societies work for a standard drivers license law, as advocated by the National Safety Council and approved by the American Medical Association. States having this law have reduced their vehicle death rates an average of 20 per cent, while all other states have increased their death rates

The report of the Committee on Contraception was unanimously adopted. The Association was asked to make clear to physicians their legal rights in relation to the use of contraceptives, to investigate and report on the various materials, devices and methods used in contraception, and to promote thorough instruction in medical schools with respect to both fertility and sterility. It was recommended that information and advice concerning contraception should be given only in clinics and similar establishments legally licensed to treat the sick and under medical control.

The federalization of the practice of medicine and the care of the indigent sick was discussed at length. Following the publication of the American Foundation reports, a group of physicians were said to have drafted recommendations for the development of a national health policy, the expansion of preventive medicine, federal subsidization of medical schools and hospitals, and the establishment of a federal department of health. The Medical Society of the State of New York adopted the recommendations after modifying them slightly and adding that all plans should be approved by the local medical profession before they were put into effect in any community. This society brought the matter before the House of Delegates which, after several long hearings, voted that it approves a federal health department, that it recognizes the primary importance of public health, and that the American Medical Association continue its "studies of the need for and the methods of distributing medical care, to the end that the American Medical Association shall continue to do everything possible to promote and to protect the health of the American people." It added

"The American Medical Association reaffirms its willingness on receipt of direct request to co-operate with any governmental or other qualified agency and to make available the information, observations and results of investigation together with any facilities of the Association."

Senator James Hamilton Lewis, of Illinois, asked to address the House of Delegates and his request was granted. He said there was a proposal to attempt to federalize the practice of medicine by licensing physicians who care for the indigent. He said that he brought the following message from the President of the United States "He hoped that you would find a way to co-operate with him in such methods as you would jointly find would be to the service of the helpless and the afflicted within such province as you felt government should undertake." The Board of Trustees was authorized to send a suitable reply to the President.

Since the annual session of the American Medical Association, there has been published a set of "Principles and Proposals" in the provision of medical care, apparently identical with those proposed by the physicians who made the recommendations that were discussed by the Medical Society of the State of New York and the American Medical Association. These proposals, endorsed by 430 physicians, have received considerable publicity, and it is probable that they will be again discussed in the approaching session of the American Medical Association.

Your delegate would like to be definitely instructed

as to what position he shall take in respect to these proposals, especially those relating to the federal subsidization of medical schools and hospitals

DEERING G SMITH

DR MESSINGER The Committee on Officers' Reports wishes to commend our delegate to the American Medical Association for his careful and accurate report. We move that this report be accepted and incorporated in the minutes of this meeting

This motion was seconded and was carried

DR. MESSINGER I move that this Society pass a resolution opposing the federal subsidy of medical schools and hospitals, and that our representative to the American Medical Association meeting be empowered to express our opinion on this matter

We also recommend that the Committee on Memorials and Communications draft a resolution expressing the disapproval of this society of federal subsidy of medical schools and hospitals

This motion was seconded and was carried

DR WALCK I have a list of members in Strafford County, who were voted by the Society to affiliate membership. We request that they be voted in as affiliate members of the New Hampshire Medical Society. The names are J H Bates, of East Rochester, R G Blanchard, of Dover, L W Flanders, of Dover, F L Keyes, of Rochester, M A H Hart, of Milton

DR. D G SMITH The Hillsborough County Medical Society has elected to honorary membership E B Sweet. The County Society has asked this House of Delegates to make him an affiliate member of the New Hampshire Medical Society

DR. HUBBARD We have two members of the Cheshire County Medical Society, H A Faulkner, of Keene, and Dennis Lamb, of Keene, whom we should like to recommend as affiliate members

DR SYCAMORE On behalf of the Grafton County Medical Society, I wish to present the names of F A Bogardus, of Canaan, J W Bowler, of Hanover, and G D Frost, of Hanover

DR DYE I move that the Secretary be instructed to cast one ballot, electing these men to affiliate membership in the New Hampshire Medical Society

This motion was seconded and was carried

SPEAKER ROBINSON The Secretary has cast a ballot in favor of all of them and I declare them duly elected to affiliate membership

DR D G SMITH My attention was called, a

short time ago, to a resolution passed by this society in 1932, relating to a proposal to have a federal hospital in this state. It seemed that at that time, all ex-service men could be well taken care of in the existing hospitals in the State, and that, if necessary and if thought best, the Federal Government could pay for their care just as well and probably a great deal more cheaply in the local hospitals

Therefore, in 1932, the House of Delegates passed the following resolution

We protest against the multiplication of hospitals designed largely for the care and treatment of ex service men suffering from diseases contracted since their discharge from the service, and we recommend that the facilities offered by existing civilian hospitals be more largely utilized. We further recommend that copies of this resolution be sent to our representatives in Congress

I move that this present House of Delegates reaffirm this resolution, and that copies of it be sent to our representatives in Congress

This motion was seconded and was carried

SPEAKER ROBINSON Is there any other new business to come before the meeting at this time? If not, the Chair awaits a motion to adjourn

DR. DYE Mr Speaker, I move that we adjourn this meeting of the House of Delegates, to reconvene at eight-thirty o'clock tomorrow morning

This motion was seconded, and was carried

SPEAKER ROBINSON I now declare this meeting adjourned

Whereupon, the Monday Evening Session of the House of Delegates was adjourned at ten-forty o'clock in the evening, to reconvene at eight-thirty o'clock on Tuesday morning, May 17, 1938

* * *

The House of Delegates convened at the Hotel Carpenter, Manchester, on Tuesday morning, May 17, 1938, at eight-thirty o'clock, with Speaker Richard W Robinson, of Laconia, presiding

The following members answered the roll call

The President, ex-officio
The Vice-President, ex-officio
The Secretary-Treasurer, ex-officio
Chester L. Smart, Laconia
A Philip LaFrance, Laconia
William J Paul Dye, Wolfeboro
Francis J C Dube, Center Ossipee
Osmon H Hubbard, Keene
Norris H Robertson, Keene

William M Bronson, Lancaster
Robert M Deming, Glenduff
Leslie K. Sycamore, Hanover
John C Eckels, Lisbon
Deering G Smith, Nashua
Clarence E Dunbar, Manchester
George V Fiske, Manchester
Herbert B Messinger, Franklin
Henry C Sanders, Claremont
Edna Walck, Dover
Addison Roe, Newport
Emery M Fitch, Claremont
Henry O Smith, Hudson

SPEAKER ROBINSON We will hear the report of the Committee on Memorials and Communications

DR W J PAUL DYE Concerning hospitalization insurance, your committee recommends that this question be referred to the Committee on Public Relations for further study and for detailed recommendations to be later submitted to the House of Delegates

DR LADD I move that this recommendation be adopted

This motion was seconded

SPEAKER ROBINSON This matter is now open for discussion

SECRETARY METCALF The Committee on Public Relations would be glad to have your opinion as to what should be done in the event that the Hospital Superintendents' Club wishes to put this plan into effect before the House of Delegates meets again

DR. FISKE May I ask what the attitude of the American Medical Association is toward this matter?

SPEAKER ROBINSON They favor it.

DR. LORD I think it would be well to put ourselves on record as being in favor of it

SPEAKER ROBINSON Would you like to amend the motion before the House to that degree? That would give us an expression of opinion of the House of Delegates

DR LORD Yes, that we approve the principle of insurance

SPEAKER ROBINSON Dr Lord has moved to amend the motion before the House that it go on record as approving the principle of hospital insurance, and that the Committee on Public Relations, in co-operation with the Hospital Superintendents' Club, be empowered to act for the House

of Delegates with any plan that they mutually agree upon as being most advantageous in carrying out the principle of insurance

The amendment was seconded and was carried

SPEAKER ROBINSON Now, the question is on the original motion of the report of the Committee on Memorials and Communications Those in favor of accepting the report will signify by saying "aye"

The motion was carried

DR DYE Your committee proposes the following resolution

WHEREAS, by the death of Dr Charles Duncan, secretary of the State Board of Health, the New Hampshire Medical Society has lost a member who has served his state long and faithfully in the interests of medicine, therefore be it

RESOLVED, That the New Hampshire Medical Society appreciates, in the death of Dr Charles Duncan, the loss to the State of a competent and sincere official, and the loss to the many who worked with him of an earnest and true friend He worked steadily for the progress of public health Following his graduation from Harvard Medical School in 1903, he became bacteriologist for the New Hampshire Board of Health, acting as bacteriologist and pathologist for the State Hospital, the Margaret Pillsbury Hospital and the New Hampshire Memorial Hospital. Dr Duncan became secretary of the State Board of Health in 1918, under his direction, the Laboratory of Hygiene was established, and the work of the department increased greatly in scope, in line with the significant advance in the field of preventive medicine. Through his long period of service he gave wholeheartedly of his time and energy, accomplishing much toward the prevention of disease and the prolongation of life in a state that benefited greatly thereby, and be it further

RESOLVED, That these words be incorporated in the records of the New Hampshire Medical Society, and that a copy be sent to Mrs Duncan as an expression of the sympathy and esteem held by the members of this Society

Your Committee recommends that the memorial communication concerning the death of Dr Charles Duncan be incorporated in full

SPEAKER ROBINSON You have heard the recommendation of the Committee on Memorials and Communications What is your pleasure?

DR SMART I move that the recommendation be adopted

This motion was seconded and was carried

DR DYE I have a summary of the Wagner Bill

Statement of Hon Robert F Wagner, United States Senator from New York, in the Senate of the United States, on April 11, 1938 Senate Resolution 265

It is proposed that there be established a select committee to be composed of three senators, no more than two of whom shall be members of the same political party,

to be appointed by the president of the Senate. The committee is authorized and directed to make a general study, investigation and analysis of the adequacy and cost of medical care in relation to income and ability to pay, and of ways and means to maintain and improve the health of the people of the United States, including but not limited to the following (1) expansion of federal aid, (2) extension of governmental aid, by co-operation of state and federal governments, (3) operation of existing public and private health insurance or group-health systems, (4) utilization of professional experts in the planning, direction and execution of the foregoing measures, (5) any other subject, matter or thing adjudged by the committee to be relevant or germane to the foregoing subjects of inquiry

The committee shall report to the Senate on or before February 1, 1939, the results of its study, together with its recommendations for appropriate legislation

Concerning Senator Robert F Wagner's resolution, your committee recommends that the House of Delegates go on record as favoring an unbiased investigation of national health problems We feel, however, that such an investigation was adequately covered recently by the American Medical Association, and this report is available for Senator Wagner's committee, furthermore, that this question be referred to the Committee on Public Relations, with power to act concerning such, according to developments in the future.

DR SYCAMORE I move the adoption of the report

This motion was seconded and was carried

DR DYE There are two senate and house bills pending for a new building for the Army Medical Library and Museum

Your committee recommends that the House of Delegates go on record as strongly endorsing the passing of S 3919 and H R 10455, bills proposing to authorize the construction of a new building for the Army Medical Library and Museum in Washington

DR SMART I move the adoption of the recommendation

This motion was seconded and was carried

DR DYE We recommend the adoption of the following resolution by the House of Delegates

WHEREAS certain proposals pertaining to the compulsory care of the indigent sick under federal control were mentioned by Senator James Hamilton Lewis at the June 10, 1937, meeting of the House of Delegates of the American Medical Association at Atlantic City, New Jersey, therefore, be it

RESOLVED, That the House of Delegates of the New Hampshire Medical Society go on record as unreservedly condemning the proposals presented by Senator Lewis relating to socialized medicine, that we purposely declare opposition to the enactment of any such plans by all

legitimate means at our disposal, and urge every New Hampshire physician to oppose this measure and to refuse to co-operate with any group or agency established to carry out Senator Lewis's outlined purposes, and be it further

RESOLVED That each county society in the State of New Hampshire be sent a copy of this resolution with the request of endorsing it, also that a copy be sent to New Hampshire representatives and senators in Congress

DR DUBE I move that the recommendation be adopted

This motion was seconded and was carried

SPEAKER ROBINSON Is there any other business to come before this meeting this morning? If not, a motion to adjourn is in order

DR DUBE I move that we adjourn until eight-thirty tomorrow morning, May 18, 1938

This motion was seconded and was carried

Whereupon, the meeting was adjourned at nine forty-five o'clock in the morning, to re-convene on May 18, 1938, at eight-thirty o'clock in the morning

* * *

The House of Delegates convened at the Hotel Carpenter, Manchester, on Wednesday morning, May 18, 1938, at eight-thirty o'clock, with Speaker Richard W Robinson, of Laconia, presiding

The following members answered the roll call

The President, ex-officio
The Vice-President, ex-officio
The Secretary-Treasurer, ex-officio
Herbert B Messinger, Franklin
William J Paul Dye, Wolfeboro
William M Bronson, Lancaster
Deering G Smith, Nashua
Henry O Smith, Hudson
Clarence E Dunbar, Manchester
Wendell P Clare, Portsmouth
Frederic P Lord, Hanover
A Philip LaFrance, Laconia
Francis J C Dube, Center Ossipee
Addison Roe, Newport

SPEAKER ROBINSON The first business of the meeting is the report of the Nominating Committee, by Dr Sanders

Report of Nominating Committee

OFFICERS

President Clarence O Coburn, Kenneth Churchill, George S Emerson.
Vice President James B Woodman, Richard E Wilder, Elmer M Miller
Councilors Clifton S Abbott, Belknap, Arthur W Burnham, Grafton.

Trustee Alpha H. Harriman, Emeritus, Samuel T Ladd

Speaker of the House of Delegates William J Paul Dye.

Vice-Speaker Fred Fernald.

Necrologist Henry H. Amsden.

Delegate (American Medical Association) Deering G Smith

Alternate Delegate Emery M. Fitch

Delegates (New England States Meetings)

Maine Wendell P Clare, Lawrence R Hazzard
Vermont Loren F Richards, John J Boardman.
Massachusetts William J Paul Dye, Arthur W Burnham.
Rhode Island Ellsworth M. Tracy, Benjamin E Sanborn
Connecticut Earl J Gage, Osmon H. Hubbard

COMMITTEES

Committee on Amendments to Constitution and By-laws

Fred E. Clow, Emery M Fitch, Louis W Flanders

Committee on Control of Cancer

George C Wilkins, Howard N Kingsford, George F Dwinell

Committee on Medical Economics

Timothy F Rock, 1939, Leslie K. Sycamore, 1940, Richard W Robinson, 1941

Committee on Medical Education and Hospitals

John P Bowler, James W Jameson, Harris E. Powers

Committee on Mental and Social Hygiene

Charles H Dolloff, Benjamin W Baker, Charles H Weaver

Committee on Public Relations

President, Vice President, and Secretary Treasurer, ex officio, Robert J Graves and John F Holmes

Committee on Publication

Carleton R. Metcalf, Warren H. Butterfield, Ellsworth M. Tracy

Committee on Scientific Work

Carleton R. Metcalf, Frederick P Scribner, Nathan T Milliken.

Committee on Tuberculosis

Robert B Kerr, Robert M Deming, John D Spring

Advisory Committee on Medical Relief

Robert J Graves, John P Bowler, Roland J Royce.

Committee on Child Health

Cohn C Stewart, Jr, Travis P Burroughs, Franklin N Rogers

Committee on Maternity and Infancy

Robert O Blood, Benjamin P Burpee, Chester F Magill

April 6, 1938 Luncheon meeting at which Dr Tracy Putnam, of the Boston City Hospital and the Department of Neurology, the Harvard Medical School, spoke of 'Modern Methods of Treatment for Diseases of the Nervous System.' This was an admirable review of medical and surgical advances in neurological treatment.

HENRY H. AMSDEN, *Councilor*

DR D G SMITH I move that this report be accepted

This motion was seconded and was carried

DR LADD I move that the Secretary be instructed to notify each and every Councilor that he shall make an effort to get his report to the House of Delegates next year without fail

This motion was seconded and was carried

SPEAKER ROBINSON The next business to come before the meeting is the determination of the place of the next meeting

DR DUNBAR I think the local members would be glad to invite the meeting to Manchester next year, as usual. If there are no other invitations I move that we hold our next annual meeting in Manchester

SPEAKER ROBINSON Does anyone wish to invite the Society elsewhere? Do I hear a second to the motion of Dr Dunbar?

This motion was seconded and was carried

SECRETARY METCALF I move that we express our gratitude to the Manchester medical group for the work which they have done this year and the courtesy they have shown in inviting us to come again

This motion was seconded and was carried

SPEAKER ROBINSON Is there any other new business to come before the meeting? If not, the Chair will entertain a motion to adjourn

DR LADD I move that we adjourn the 1938 meeting of the House of Delegates of the New Hampshire Medical Society

This motion was seconded and was carried

Whereupon, the 1938 meeting of the House of Delegates was adjourned at nine-thirty o'clock in the forenoon, on May 18 1938

SPEAKER ROBINSON You have heard the report of the Nominating Committee. The first order of business is the election of a president. The meeting is now open for any other nominations

DR. LADD I move that the nominations be closed

This motion was seconded and was carried

Ballots were then given to the delegates present

DR SANDERS Mr Speaker, there were thirteen ballots cast and Clarence O Coburn received thirteen votes

SPEAKER ROBINSON I declare Clarence O Coburn elected as president. The next order of business is the election of a vice-president. The meeting is now open to any further nominations

DR DYE I move that nominations be closed

This motion was seconded and was carried

Ballots were then given to the delegates

DR SANDERS The total number of votes cast was fourteen, James B Woodman received thirteen votes and Elmer M Miller received one vote

SPEAKER ROBINSON I declare James B Woodman elected as vice-president

DR LADD I move that the Secretary cast one ballot for the election of the rest of the slate, as presented by the Nominating Committee.

This motion was seconded

A vote by ballot was then taken, with reference to the rest of the officers

SPEAKER ROBINSON The ballot is unanimously "yes" Therefore, I declare the rest of the slate, as read by the Nominating Committee, elected

Dr Dye, chairman of the Committee on Memorials and Communications, has a further report to make

DR DYE We have this resolution to present

WHEREAS, We are in principle opposed to state medicine, inasmuch as we feel that such is not only detrimental to the best interests of patient and physician alike, but also that it destroys individual initiative and so deterts scientific medical progress, therefore, be it

RESOLVED, That the House of Delegates of the New Hampshire Medical Society go on record as opposing federal subsidization of medical schools and hospitals, since such is a form of state medicine, furthermore, be it

RECOMMENDED, That this matter be delegated to the Committee on Public Relations with power to act as future developments make advisable.

DR. LADD I move that this resolution be adopted

This motion was seconded and was carried

DR MESSINGER I have one further report to make. The Committee on Officers' Reports thanks the Committee on Medical Economics for its consideration of an unofficial fee schedule, and recommends that no action be taken on this matter at this time

In view of the fact that the subject of hospitalization insurance has been discussed and referred to the Committee on Memorials and Communications, no additional action is recommended by this committee

The House of Delegates has already voted to continue the Committee on Medical Economics

DR MESSINGER I move that that portion of the report be adopted

This motion was seconded and was carried

SPEAKER ROBINSON Are there any Councilors' reports at this time?

Councilor's Report for Merrimack County

July 7, 1937 Eagle Hotel dinner meeting. Subject "Bang's Disease." Dr Thomas M Dudley discussed the clinical aspects, Dr Robinson W Smith the veterinary aspects and Dr Travis P Burroughs the epidemiology of the disease. Dr Samuel T Ladd, of Portsmouth, president of the New Hampshire Medical Society, addressed the meeting, and Dr Thomas Walker, 2nd, Dr Cornelia Walker and Dr Harold W Epling were voted into membership

October 6, 1937 Eagle Hotel dinner meeting. Dr Clough, vice president, presided in the absence of the president, Dr Parsons. Dr Reeves Betts, of the Lahey Clinic, spoke of new developments in the field of thoracic surgery, followed by a moving picture film on the subject. Dr Simon Stone, Dr Ellsworth M Tracy, Dr Oliver P Hayward and Dr Conrad Ranger were voted into membership

January 5, 1938 Annual meeting at the Eagle Hotel. Dr Channing Frothingham, of the Faulkner Hospital, Boston, spoke on the "Principles and Proposals" of the Committee of Physicians. Dr Carleton R. Metcalf discussed Dr Frothingham's paper, taking the negative side of the question. Officers elected were: president, Dr William P Clough, vice president, Dr J Dunbar Shields, secretary treasurer, Dr Warren H Butterfield, censors, Dr Henry H Amsden (3 years), Dr McLean J Gill (2 years) and Dr William P Clough (1 year), Delegates, Dr Thomas M Dudley, Dr Herbert B Messinger, and Dr Warren H. Butterfield, auditors, Drs Harold W Epling and Eugene Chamberlain.

Drs Edward Putnam of Warner and Robert Beaudet, of Franklin, and Drs Joseph Clough and William Clough, of New London, were elected to membership

X-RAY INTERPRETATION

DR. GEORGE W. HOLMES Most of the evidence on these films is negative. He has a considerable mass of calcified glands at both lung roots. There is no definite elevation of the diaphragm and no evidence of active disease in the chest, or enlargement of the heart. In the films taken of his abdomen the outlines of the kidney are fairly well shown on the right side and I should say that it was about normal in size and shape. The liver edge is also seen. I should not say it was enlarged although there is some other evidence that does suggest it in this film in that the stomach seems to lie more to the left than is usual, which is suggestive of enlargement of the left lobe of the liver. I do not believe there is general enlargement of the liver. We also made a study of the esophagus but there is no evidence of esophageal varices, which might help some. In the colon we have an abnormality of position. The cecum apparently lies high under the edge of the liver, and this I take to be the appendix. I think this is the lower margin of the liver. The hepatic flexure is pushed down a bit. The colon empties normally and shows a normal mucosal pattern. I should agree with the interpretation in the report that there is no evidence of intrinsic disease. Certainly there is nothing that suggests malignant disease except possibly the vague suggestion of an enlarged lobe of the liver.

DIFFERENTIAL DIAGNOSIS (continued)

DR. BREED We have two bits of evidence, the paragraph stating that the liver on direct examination was markedly enlarged, and the statement that there was a suggestive mass in the epigastrium by x-ray.

DR. MALLORY It was observed by a number of people and all agreed upon it.

DR. HOLMES I think you should take the clinical evidence in a question of enlargement of the liver. It is certainly as good if not better than the x-ray, both are unreliable.

DR. ARTHUR W. ALLEN If I remember correctly, this liver felt somewhat nodular to some of us.

DR. BREED That is interesting—and new evidence.

DR. MALLORY Also, I might remark, on statistical grounds an unreliable observation.

DR. ALLEN The history does not state it, but this man had considerable pain radiating through to his back.

DR. HOLMES I should like to ask why the Graham test was unsatisfactory.

DR. MALLORY It was unsatisfactory because large amounts of barium were retained in the

colon. Presumably there were overlapping shadows.

DR. BREED The problem now resolves itself to this: Did this man suffer from primary hypertrophic biliary cirrhosis or did he have primary cancer of the bile ducts or metastatic cancer of the liver? It is fairly clear that he had no portal cirrhosis. He had no ascites, no splenic enlargement, no esophageal varices, and in view of the forty per cent dye retention a negative Takata-Ara test is probably good evidence against portal cirrhosis. I cannot explain on the basis of biliary cirrhosis alone a 4+ guaiac test. We recently had a discussion as to the production of varicosities of the esophagus caused by biliary cirrhosis alone. It is my impression that biliary cirrhosis as such does not produce varicosities of the esophagus with consequent bleeding.

Were there any negative guaiacs on the stools?

DR. MALLORY I could find the report of only one stool examination and that showed the positive guaiac.

DR. BREED We are told in one place that the liver was smooth and tender, in another, that there were some nodules in it. Which opinion shall we accept? Let us go back over the history. It is true that he had lost only 8 lb., malignant disease is unlikely. His story of a sensation of fullness and inability to eat much because he was stuffed with food would put it on a mechanical basis rather than a toxic basis, it seems to me. He was operated on for diagnosis obviously, not for treatment, and it is our duty to guess what was found at the laparotomy. My guess is that primary biliary cirrhosis comes first, because I cannot find anything in the story or in the x-ray or in the laboratory work to point to the source of a malignant disease or to portal cirrhosis. Of course, the second guess is primary carcinoma of the liver.

DR. WYMAN RICHARDSON Would you consider a diagnosis of catarrhal jaundice?

DR. BREED Yes, I would entertain it.

A PHYSICIAN The 40 per cent dye retention is a good deal for catarrhal jaundice, is it not?

DR. BREED I do not know.

DR. MALLORY It seems to me that would indicate a certain amount of decreased liver function. I cannot remember your having mentioned in your discussion the "shots of Scotch and gin." Do you take them seriously?

DR. BREED No, because there is no evidence here that this is portal cirrhosis. If he had no ascites, no splenomegaly, and no demonstrable esophageal varices, and has a negative Takata-Ara test, with a 40 per cent dye retention, I should be very much against a diagnosis of portal cir-

TRACY B. MALLORY, M.D., *Editor*

CASE 24251

PRESENTATION OF CASE

A forty-seven-year-old, white, American electrical engineer entered the hospital with the complaint of stomach trouble of four weeks' duration.

Four weeks before entry he had a sudden attack of nausea followed by two episodes of vomiting. This occurred in the evening. He felt rather poorly at that time, but the following morning felt much better. However, he noticed the onset of a dull heavy ache in the abdomen around the umbilicus and had the sensation that there was a lump in that region. He also found that he was unable to eat a full meal without having the sensation of being stuffed with food, although he had no more nausea or vomiting. He had considerable flatus, but no borborygmus, and no actual abdominal pain. During his illness his stools were darker than usual and for the first time in his life he had to take a daily cathartic in order to have bowel movements. His symptoms continued practically unchanged up to the time of entry. He had no hematemesis, melena, or jaundice. During his illness he had lost about 8 lb in weight. For ten years before entry he had taken four or five "shots" of Scotch whisky or gin each night, but stated that he was never drunk. His past history was otherwise negative, and his family history was noncontributory.

Physical examination revealed a fairly well-developed and nourished man showing evidence of recent weight loss. The skin was somewhat sallow, and there was a telangiectasis measuring 1 mm in diameter at the mid-point of the right costal margin. The sclerae were slightly icteric. The heart and lungs were negative, and the blood pressure was 135 systolic, 80 diastolic. The right diaphragm was definitely higher than the left. The liver was markedly enlarged, extending four fingerbreadths below the costal margin. The edge was smooth and very tender. The spleen could not be made out. A rectal examination was negative.

The temperature was 99°F, the pulse 110. The respirations were 20.

The urine contained 1+ bile but was otherwise negative. The blood showed a red-cell count of 4,380,000 with 80 per cent hemoglobin and a white-cell count of 7800 with 89 per cent polymorphonu-

clears. The stools were brown in color and gave a 4+ guaiac test. The icteric index was 12, and the van den Bergh on the blood serum was 36 mg per cent, biphasic. A Takata-Ara test was negative, a blood Hinton was negative. The serum protein was 6 gm per cent. A sedimentation rate determination gave a maximum fall of 21 mm in fifteen minutes with 63 per cent plasma. A liver function test gave, 40 per cent dye retention.

An x-ray of the chest and a flat film of the abdomen were normal except for a suggestive mass in the epigastrium, corresponding to the left lobe of the liver. Examination of the gastrointestinal tract by a gastrointestinal series and a barium enema showed no evidence of intrinsic disease. A Graham test was unsatisfactory.

An electrocardiogram showed occasional auricular premature beats but no other abnormalities.

An exploratory laparotomy was performed thirteen days after entry.

DIFFERENTIAL DIAGNOSIS

DR. WILLIAM B. BREED. In order to make this short I am going to assume that there was nothing above the diaphragm to warrant a diagnosis of liver disturbance due to disturbed circulation, either in the pulmonary or coronary circuit. We shall confine our attention to the organs below the diaphragm.

This man obviously had either some intrinsic liver disease, some disease outside which was causing pressure, or he had metastases to the liver.

In the first place, I should like to know whether that temperature of 99°F was an average temperature and whether while he was in the hospital he became so sick that they operated on him as a form of treatment.

DR. TRACY B. MALLORY. I do not believe he had ever had any significant grade of fever.

DR. BREED. I assume he stayed in the hospital to be studied, and that finally it was decided to explore his abdomen for diagnosis.

He had no anemia. He had mild jaundice. The Takata-Ara test was negative, and there was 40 per cent dye retention on the liver test. The sedimentation rate was high, the corrected rate being about 1 mm per minute. The statement that the gastrointestinal series and barium enema showed no evidence of intrinsic disease seems to me somewhat evasive, and makes me suspicious that there was something outside the gastrointestinal tract which might help us in making a diagnosis, perhaps some malignant disease with metastases. I should like to review the x-ray films to see if there is anything that would help us to make a diagnosis of primary carcinoma of the liver.

bread and tea. During the five weeks before entry constipation became much more severe, so that it was necessary for him to take cathartics three or four times a week. Some of his stools were black in color, and on three occasions were definitely tarry. During the two months before entry he lost 15 lb in weight. He had no nausea, vomiting, hemoptysis, jaundice, fever, chills or red blood in his stools. He had slight dyspnea on exertion and slight edema of the ankles in the evening, but no marked cardiorespiratory symptoms. Three years before entry he had a suprapubic prostatectomy for urinary frequency, urgency, dribbling and nocturia. After operation the frequency and nocturia persisted, but the other symptoms were relieved. His past history was otherwise essentially negative and his family history noncontributory.

Physical examination revealed a well-developed and nourished man in no acute discomfort. Both pupils were slightly irregular and reacted sluggishly to light. There was an old fracture of the left clavicle with 4 cm of shortening and resulting deformity of the chest. There were bulging posteriorly below the scapula and flaring of the rib cage of the left costal margin. The left diaphragm was slightly elevated and did not move on deep inspiration. Beneath the angle of the scapula on the left there were slight dullness, diminished tactile and vocal fremitus, and absent breath sounds. Above the angle of the scapula breath sounds were diminished. Anteriorly in the left axilla the percussion note was tympanic, and definite peristaltic sounds could be heard. The heart was not enlarged, but there was an apical systolic murmur. The blood pressure was 180 systolic, 120 diastolic. There was some tenderness without spasm in the right-upper quadrant, and the liver edge was percussed 3 cm below the costal margin. There was a suprapubic scar with a small hernia. Proctoscopy was negative except for a small polypoid thickening of the mucosa on the anterior wall, 6 cm from the anus.

The temperature was 98.6°F., the pulse 75. The respirations were 20.

The urine examination was negative except for numerous white cells in the sediment. The blood showed a red-cell count of 5,100,000, with 80 per cent hemoglobin, and a white-cell count of 7000. Guaiac tests on five stools were all negative. A blood Hinton test was negative. An electrocardiogram was within normal limits.

An x-ray of the chest showed a normal right diaphragm and lung. On the left the diaphragm was elevated and showed paradoxical motion with gas in the bowel beneath it. The left lung field was clear. The heart was normal in appearance, and the aorta was tortuous and perhaps slightly dilated. A gastrointestinal series showed a normal

esophagus. As the barium enema entered the stomach, the fundus was seen to be the most dependent portion. The barium ascended to the body, which was the highest portion of the stomach, and lay directly beneath the high paralyzed diaphragm. From this point the barium descended to the pyloric antrum which lay directly over the cardia. The duodenal cap which was directed downward was constantly irregular and showed a definite fleck. Two barium enemas were negative for intrinsic disease, although there was marked spasm of the entire descending colon. However, relaxation and filling were observed along its entire extent, and no abnormalities were recognizable in the mucosal pattern. X-rays of the spine and pelvis showed no evidence of metastases. There were areas of calcification in the region of the left kidney and a long dense oval shadow in the left side of the true pelvis which could have represented a large ureteral stone. An intravenous pyelogram showed normal filling of the pelves, calices and ureters, except in the region of the above-described area of calcification where the left ureter failed to fill. However, there was no other evidence of obstruction.

He remained in the hospital three weeks and improved considerably on an ulcer regime. He was discharged on a six-meal bland diet with tincture of belladonna.

Final admission (sixteen months later). The interval history was very incomplete because of lack of co-operation. Following discharge he gained weight and felt reasonably well except for occasional epigastric distress. He followed his diet faithfully, but took little belladonna. A few weeks before re-entry he began to lose his appetite, and both his epigastric pain and his constipation increased. About two weeks before re-entry he noticed swelling of his abdomen and ankles and began to have a cough productive of moderate amounts of thick yellow sputum. He had some nausea, and his stools became tarry. He was given white pills by his physician which seemed to increase his pain. Gradually he became weaker and somewhat irrational. During the week before re-entry his stools became loose and his bowels were apt to move involuntarily when he coughed. On the day before re-entry he vomited small amounts of black material on three occasions. He was very weak, almost fainted several times and passed many black loose stools.

Physical examination revealed a well-developed and nourished man in no acute distress but apparently very weak and somewhat drowsy. There was marked pallor of the skin and mucous membranes. The examination of the chest was essentially the same as on the previous admission. The

rhosis. However, he has some blood in his stool, and I cannot explain that.

DR ALLEN I was the mechanic in this case for the purpose of diagnosis, just as Dr Breed has suggested. There was a good deal of discussion before operation as to the diagnosis, and a considerable amount of thought was given to the possibility of carcinoma of the pancreas with metastases to the liver. At operation, however, there was no evidence whatever of malignant disease. There was no evidence of disease in the gall bladder or bile ducts. The liver was uniformly enlarged, and it was obvious that his disease was one of intrinsic liver disorder. A biopsy from the liver edge was taken and no more done.

DR BREED Where did his bleeding come from?

DR ALLEN I have a feeling that it was a single observation and probably not from blood in the gastrointestinal tract.

PREOPERATIVE DIAGNOSIS

Carcinoma of pancreas with metastasis to liver

DR BREED'S DIAGNOSIS

Hypertrophic biliary cirrhosis of the liver

ANATOMICAL DIAGNOSIS

Acute alcoholic cirrhosis

PATHOLOGICAL DISCUSSION

DR MALLORY Over and over again at these exercises we have had cases of cirrhosis of the liver with one or sometimes many positive guaiacs on the stools and nothing at autopsy to explain them. I am sure any patient with jaundice can have from time to time positive guaiacs in the stool.

The biopsy in this case showed liver cells which were very largely filled with fat but here and there among the fatty cells were some that contained quite clear hyaline degeneration of the type that is found in alcoholic cirrhosis, and that, so far as we know, is specific for it. This is a type of case that we see comparatively seldom at this hospital. At the Boston City Hospital within the past four or five years they have had almost an epidemic of it. Their patients have comprised a group of patients from the lowest social strata who have been drinking very excessively, ever since prohibition, alcohol which they can purchase without prescription at any drugstore. Many have died of acute liver insufficiency with histories of drinking from a pint to a quart, sometimes even more of slightly diluted alcohol. That type of case does not seem to come into this hospital. Our most nearly similar cases have come from the private pavilions rather than the general wards. There is no doubt from the biopsy findings in

this case that it is alcoholic and not biliary cirrhosis, though it is in fact so acute that it can hardly be called a cirrhosis, there being as yet almost no fibrosis. The spleen was not enlarged. It represents the earliest initial stage. Had this same process kept up for years it would have caused an atrophic portal cirrhosis. There must always be an initial stage for portal cirrhosis. We do not often see patients in that stage because they do not die then. The subsequent history of this patient added considerable confirmatory evidence for our diagnosis. Postoperatively he developed very characteristic delirium tremens.

A PHYSICIAN There is marked decrease in liver function, if this is such an early stage.

DR MALLORY A large proportion of the liver cells were filled with fat. That certainly would not improve their function.

A PHYSICIAN There is no reason to suspect the left lobe of being enlarged? It was a very uniform enlargement, I take it.

DR MALLORY Yes, it was quite a large liver. In this stage it is possible for a liver to weigh 4 or 5 kg., which is about as large as any liver we see except in occasional cases of metastatic disease.

CASE 24252

PRESENTATION OF CASE

First admission A seventy-six-year-old, unemployed Irishman entered the hospital with the complaint of pain in the right side of his chest of six weeks' duration.

All his life he had had attacks of indigestion after meals which lasted only a few minutes and were relieved by soda. He also had constipation, and for many years had noticed that if he swallowed food or liquids very rapidly they would appear to stop temporarily in his epigastrium. Rubbing that area would dislodge them. About three months before entry he began to have attacks of dull sickening pain in the upper abdomen which occurred after lifting heavy objects and radiated to the left chest, right-lower quadrant, right hip, down the right leg, and occasionally to both chests, to the right ear and down the right arm to the tip of the middle finger. The onset of the pain had no relation to the intake of food or to exercise. At first it was partially relieved by taking whisky, but later this aggravated the pain. He soon found that lying down always brought relief, especially if he placed several pillows beneath his back. The taking of milk and soda was also helpful. This pain became progressively worse and was practically constant during the six weeks before entry. He restricted his diet to malted milk,

bread and tea. During the five weeks before entry constipation became much more severe, so that it was necessary for him to take cathartics three or four times a week. Some of his stools were black in color, and on three occasions were definitely tarry. During the two months before entry he lost 15 lb in weight. He had no nausea, vomiting, hemoptysis, jaundice, fever, chills or red blood in his stools. He had slight dyspnea on exertion and slight edema of the ankles in the evening, but no marked cardiorespiratory symptoms. Three years before entry he had a suprapubic prostatectomy for urinary frequency, urgency, dribbling and nocturia. After operation the frequency and nocturia persisted, but the other symptoms were relieved. His past history was otherwise essentially negative and his family history noncontributory.

Physical examination revealed a well-developed and nourished man in no acute discomfort. Both pupils were slightly irregular and reacted sluggishly to light. There was an old fracture of the left clavicle with 4 cm of shortening and resulting deformity of the chest. There were bulging posteriorly below the scapula and flaring of the rib cage of the left costal margin. The left diaphragm was slightly elevated and did not move on deep inspiration. Beneath the angle of the scapula on the left there were slight dullness, diminished tactile and vocal fremitus, and absent breath sounds. Above the angle of the scapula breath sounds were diminished. Anteriorly in the left axilla the percussion note was tympanic, and definite peristaltic sounds could be heard. The heart was not enlarged, but there was an apical systolic murmur. The blood pressure was 180 systolic, 120 diastolic. There was some tenderness without spasm in the right-upper quadrant, and the liver edge was percussed 3 cm below the costal margin. There was a suprapubic scar with a small hernia. Proctoscopy was negative except for a small polypoid thickening of the mucosa on the anterior wall, 6 cm from the anus.*

The temperature was 98.6°F, the pulse 75. The respirations were 20.

The urine examination was negative except for numerous white cells in the sediment. The blood showed a red-cell count of 5,100,000, with 80 per cent hemoglobin, and a white-cell count of 7000. Guaiac tests on five stools were all negative. A blood Hinton test was negative. An electrocardiogram was within normal limits.

An x-ray of the chest showed a normal right diaphragm and lung. On the left the diaphragm was elevated and showed paradoxical motion with gas in the bowel beneath it. The left lung field was clear. The heart was normal in appearance, and the aorta was tortuous and perhaps slightly dilated. A gastrointestinal series showed a normal

esophagus. As the barium enema entered the stomach, the fundus was seen to be the most dependent portion. The barium ascended to the body, which was the highest portion of the stomach, and lay directly beneath the high paralyzed diaphragm. From this point the barium descended to the pyloric antrum which lay directly over the cardia. The duodenal cap which was directed downward was constantly irregular and showed a definite fleck. Two barium enemas were negative for intrinsic disease, although there was marked spasm of the entire descending colon. However, relaxation and filling were observed along its entire extent, and no abnormalities were recognizable in the mucosal pattern. X-rays of the spine and pelvis showed no evidence of metastases. There were areas of calcification in the region of the left kidney and a long dense oval shadow in the left side of the true pelvis which could have represented a large ureteral stone. An intravenous pyelogram showed normal filling of the pelves, calices and ureters, except in the region of the above-described area of calcification where the left ureter failed to fill. However, there was no other evidence of obstruction.

He remained in the hospital three weeks and improved considerably on an ulcer regime. He was discharged on a six-meal bland diet with tincture of belladonna.

Final admission (sixteen months later). The interval history was very incomplete because of lack of co-operation. Following discharge he gained weight and felt reasonably well except for occasional epigastric distress. He followed his diet faithfully, but took little belladonna. A few weeks before re-entry he began to lose his appetite, and both his epigastric pain and his constipation increased. About two weeks before re-entry he noticed swelling of his abdomen and ankles and began to have a cough productive of moderate amounts of thick yellow sputum. He had some nausea, and his stools became tarry. He was given white pills by his physician which seemed to increase his pain. Gradually he became weaker and somewhat irrational. During the week before re-entry his stools became loose and his bowels were apt to move involuntarily when he coughed. On the day before re-entry he vomited small amounts of black material on three occasions. He was very weak, almost fainted several times and passed many black loose stools.

Physical examination revealed a well-developed and nourished man in no acute distress but apparently very weak and somewhat drowsy. There was marked pallor of the skin and mucous membranes. The examination of the chest was essentially the same as on the previous admission. The

blood pressure was 120 systolic, 70 diastolic. The abdomen was pendulous and somewhat tympanitic. There was slight tenderness in the midepigastrium, and the liver edge was percussed 4 cm. below the costal margin. No masses were felt. Rectal examination was negative. The patient was lying in a thin brownish-black rectal discharge.

The temperature was 99.5°F., the pulse 110. The respirations were 20.

The urine examination was negative except for numerous white cells in the sediment. The blood showed a red-cell count of 2,500,000 with 55 per cent hemoglobin, and a white-cell count of 14,300 with 90 per cent polymorphonuclears. The guaiac test on the stool was 4+. The blood Hinton was negative. The nonprotein nitrogen of the blood serum was 62 mg. per cent. A urine culture gave nonhemolytic streptococci and a heavy growth of *Bacillus proteus*.

He continued to pass changed blood by rectum, some of which was dark red in color. He was put on a first-stage gastric diet and given a transfusion but in spite of this his red-cell count fell to 970,000 and he died on the fourth day.

DIFFERENTIAL DIAGNOSIS

DR. ALLEN BRAILEY. I am particularly interested to know whether the x-ray examination indicates that all the abdominal organs were beneath the diaphragm.

DR. GEORGE W. HOLMES. Yes. I would interpret this as evidence of paralysis of the diaphragm without an explanation of the cause. The stomach was inverted so that the greater curvature was in contact with the diaphragm and the lesser curvature pointing down. I think this happens fairly frequently when the diaphragm is paralyzed. Sometimes it is accompanied by torsion, but I do not think that is so here. The description of the deformity of the duodenum with a fleck suggests an active duodenal ulcer. It is also stated that there is a stone in his kidney as well as ureter. The barium enemas were negative except for increased irritation in the colon.

DR. BRAILEY. It seems to me that when this patient was discharged the first time there were at least three diagnoses one could make. He presumably had ureteral calculus of some size, but it does not seem to have interfered with the function of the kidney or ureter. He also had a duodenal ulcer. The third diagnosis involves the question, What was the matter with his diaphragm and the left side of his chest? I believe he had eventration of the diaphragm. It is difficult to differentiate eventration and hernia, but there is a categorical statement here about the position of the diaphragm which makes hernia unlikely.

Eventration of the diaphragm is a very rare condition. There are about twenty times more diaphragmatic hernias than eventrations, and when it occurs it is on the left side about twenty times oftener than on the right side. It is four times commoner in men. It was first described in 1784 by Pyle and given its present name in 1829 by Cruveilhier. It is a very poor name but from long usage it is still retained. There has been a great deal of discussion as to the cause of eventration. Most people feel it is congenital because there is hypoplasia of the left lung, not atelectasis. Furthermore there seldom appears to have been mechanical cause that could have brought it on. Often it has been discovered very early in life. The diagnosis is made almost entirely by x-ray and positively by pneumoperitoneum, whereby one can demonstrate air under the diaphragm and above the abdominal viscera. Dr. Lord in 1926, in discussing this condition, thought pneumoperitoneum a radical procedure and a dangerous one. Nowadays we use it more commonly and perhaps feel that it is less dangerous. The behavior of the diaphragm on respiration is not important. One would think there would be paradoxical motion of the paralyzed leaf. That is not always the case, — it may move normally, or not at all, or in reverse direction. Certain other points are interesting, one of which is mentioned here, — Hoover's sign, with flaring of the rib margin on the affected side because of lack of diaphragmatic pull which should be present. Furthermore the mediastinum is pulled toward the good side because the negative pressure is greater on the good side than on the side of eventration. The heart ordinarily is displaced to the right in left eventration and the diagnosis of dextrocardia is often made. There may be no symptoms at all. The condition is frequently discovered accidentally. On the other hand, very distressing symptoms such as pain after meals, may be found. Bleeding has been reported occasionally. I discovered that Verbruycke* reported a case where kinking was so severe there was necrosis of the gastric mucosa and fatal hemorrhage. There may be cough, dyspnea, cyanosis and so forth, and there may be partial obstruction of the gastrointestinal tract, either stomach or colon, from kinking of the viscera under the high diaphragm.

Coming back from these generalities to the case at hand the patient was discharged on an ulcer diet which relieved most of his symptoms. He gained weight again, and a good deal of his ill health must have been due to the ulcer. He came back sixteen months later to die of hemorrhage, I judge. The hemorrhage was not a single mas-

*Verbruycke, J. R. Jr. Eventration of the diaphragm. Surg. Gynec. & Obst. 40:415-420, 1925.

sive affair, but repeated hemorrhages in the digestive tract too frequent and too gross for compensation by blood-forming organs. The questions that arise are, Why did he bleed? And where did he bleed? We have read here of polypoid thickening of the rectal mucosa. I do not see that we can pin the hemorrhage on the colon. In the first place cancer was carefully searched for and ruled out apparently. In the second place the blood is almost entirely old changed blood. He vomited dark-brown material which was probably blood and furthermore, I do not think that bleeding from cancer of the colon is very often fatal.

Might he have had cirrhosis of the liver or esophageal varices? We have a definite report that the esophagus was normal. The liver was reported below the costal margin. Nothing was said about the upper border of the liver, which is an essential point and too often left out. In all probability the liver was not small, however, as it would be in cirrhosis which had developed to the point where fatal hemorrhage would occur. He has some evidence of ascites and edema of the ankles, but that can well be explained on the basis of hemorrhage and the lowering of blood protein and osmotic pressure of the blood.

As regards bleeding from the gastric mucosa Dr. Bock, about five years ago, reported cases of very severe (I am not sure if fatal) oozing of blood in cases of diaphragmatic hernia. It can be very extensive and while this is eventration, not hernia. I do know that similar hemorrhage can occur in eventration where the stomach or bowel is kinked.

However, we know he has duodenal ulcer and we know that duodenal ulcers can cause fatal hemorrhage, especially in a man of this age. I think he died from hemorrhage from the duodenal ulcer.

Are there any other diagnoses we ought to consider? The point is made that he had a urine culture showing nonhemolytic streptococci and *Bacillus proteus*. Dr. Albright has seen some interesting cases of *Bacillus proteus* in the kidneys where the urine was persistently alkaline, and invariably there were massive stones in the kidneys. Nothing is said about alkaline urine here, and nothing very much about the kidney stones. I should suppose that probably these were either casual contaminants or represent a minor degree of infection which commonly occurs in these old people with prostatic obstruction. Cardiac infarction might well have occurred in a man of his age but I think the drop in blood pressure and so forth can be as well explained by hemorrhage. He has been raising thick yellow sputum, but I do not know what to make of that. I think he had eventration of the diaphragm and kidney

tract stones, and duodenal ulcer with fatal hemorrhage therefrom.

X-RAY INTERPRETATION

DR. HOLMES. This film shows the position of the diaphragm on the left side and below it the viscera filled with gas. It is rather unusual with a diaphragm as high as this that there is no displacement of the heart. The opposite lung is clear. In the examination of the gastrointestinal tract the fundus of the stomach is here. This is the pylorus. This is the greater curvature, so that the stomach is exactly upside down. Then in the duodenum we have this characteristic deformity which has the appearance of a large ulcer, perhaps being the crater. Here is another film that shows the deformity in the colon. There may be some increased peristaltic activity, but there is no evidence of an organic lesion. In going through this group of films hurriedly this is the only one I could find of the urinary tract without barium and apparently there are shadows in the region of the kidney. That could be stone. There is some motion, and I would want a confirmatory film before I made a positive diagnosis of stone.

CLINICAL DISCUSSION

DR. WILLIAM B. BREED. I agree with Dr. Brailey that this man died of hemorrhage from his duodenal ulcer. There was some discussion as to whether anatomically the fracture of the clavicle could have been responsible for paralysis or crushing of the left phrenic nerve and I am not too clear anatomically about that. Could the injury of the fracture crush the phrenic nerve and produce this high diaphragm?

DR. FRANKLIN G. BALCH, JR. In the series of fractures of the clavicle in this hospital we have never seen that complication.

DR. BREED. What is the anatomic relation between the phrenic nerve and the clavicle?

DR. HOLMES. The phrenic nerve seems very deep.

CLINICAL DIAGNOSES

Bleeding duodenal ulcer with secondary anemia
Eventration of stomach and intestines
Paralysis of left diaphragm

DR. BRAILEY'S DIAGNOSES

Eventration of diaphragm
Duodenal ulcer
Nephrolithiasis

ANATOMICAL DIAGNOSES

("Eventration of the diaphragm")
Gastric ulcer with hemorrhage

Pulmonary atelectasis, left
 Nephrolithiasis, left
 Pyelonephritis, chronic, left
 Operative scar Suprapubic prostatectomy

PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The autopsy showed what one would expect in so-called eventration of the diaphragm. The left diaphragm was extremely high and the great omentum had curled up into the space immediately beneath the diaphragm so that it lay on top of all the other abdominal contents. It had pulled the colon up with it, and that in turn had rotated the stomach by traction on the gastocolic ligament so that in order, from above downward we found omentum, colon and stomach. We disagreed with the x-ray department about the location of the ulcer. We found a large, penetrating, gastric ulcer and noticed nothing in the duodenum. It was immediately adjacent to the pylorus but definitely on the gastric side. In its center was quite a large artery, evidently eroded, and the source of the hemorrhage.

There were numerous stones in the pelvis of the left kidney and a long stone in the left ureter. The kidney on that side was very atrophic and showed marked scarring — evidence of healed pyelonephritis. We have sections of the two phrenic nerves and I think there is a definite difference between the two. The one on the left shows some evidence of degeneration, the right is normal. We could not make out that the nerve was pressed upon by the clavicle deformity.

DR CHESTER M JONES There are two points in the history which I think should lead one to suspect a diaphragmatic lesion. The pain and distress were modified by change in position, there was difficulty in swallowing. The distribution of the pain, which was very marked, would also sug-

gest that he had a definite involvement possibly of more than the stomach alone, which would fit in perfectly well with an accumulation of organs under a high diaphragm and resulting traction. The other point is that the physical signs were fairly characteristic, — dullness and signs of fluid at the left base, — and yet they were not so marked as in other cases. It is not uncommon to have pleural effusion suspected and dry taps made a number of times before the diagnosis is considered.

DR. MALLORY I forgot to add that at autopsy the left lung was completely atelectatic, but that could not have been the case for any very long period before death.

DR. BRAILEY Was it a small lung?

DR. MALLORY It seemed small, naturally, because of the atelectasis. We did not attempt to blow it up and I do not know whether it would have looked small if we had done that or not. It is too bad we did not do it.

DR. BRAILEY If it were a congenital lesion it probably would be small, would it not?

DR. MALLORY Yes.

DR. GEORGE W W BREWSTER Could anything have been done by surgery?

DR. MALLORY You could certainly have done nothing about the diaphragm. Moreover, if you tacked the stomach back in normal position I do not believe it would have stayed. There was a hole there that had to be filled with something. I suppose the portion of the stomach containing the ulcer could have been resected with profit.

DR. HOLMES We had a case recently with the stomach in the same position where the surgeons turned it down and fastened it to the anterior abdominal wall.

DR. MALLORY Has it stayed there?

DR. HOLMES I do not know.

SUBSTANDARD PRACTICE OF MEDICINE

THE recently drafted resolve introduced by the Committee on Public Health of the Massachusetts Legislature is an attempt to deal in a tentative and somewhat hesitant fashion with a problem in medicine that has rarely been clearly formulated. The resolve provides for an interim study of the registration of osteopathic physicians and of chiropractors, of the creation of a so-called basic-science board and of a single board of the healing arts. This is not a new idea in Massachusetts and the placing of all persons under a single board of

registration was recommended by the commission which made its report in 1925. The resolve provides also for a study of what is sometimes called the "poison law," in the light of recent disastrous experiences with certain poisonous drugs, the traffic in which has not hitherto been regulated. This last topic need not be considered in connection with substandard practice.

The rising standards for the qualification of physicians in the past seventy-five years have worked considerable hardship on substandard practitioners of medicine while they have worked incalculable benefit for the public. In the past one hundred and fifty years, there have been chartered over four hundred and fifty medical schools in the United States, most of which proved to be ephemeral and their names have never been heard by most persons of middle age. But the urge to study and practice medicine is powerful, whatever the motive, and there has been an eruption of cults, which have sought and frequently found recognition by the legislative bodies of various states.

The history of the cult in medicine can be outlined briefly. By chance someone treats a sick person in an unusual way and the patient recovers. Other patients are treated, the successes are remembered, the failures forgotten. The happy results are attributed to the method, and soon a school of therapy based on a new theory of disease is developed. One is reminded of the advice of the wise old physician to a young patient who inquired anxiously "Shall I take this new treatment?" "By all means," he replied, "while it is still new. Its virtue will disappear when it is old."

The cult grows, holds its own for a while, wanes and disappears. Sometimes it makes a permanent contribution to the stream of medicine, but from its birth it is doomed. One cannot predict the span of its life, but a very vigorous cult may endure through three generations of men. Some die in infancy, some in childhood. It is on this account that Massachusetts should beware of giving formal recognition to cults in medicine. The

single standard of qualification for all who practice medicine, of which Massachusetts was once so justly proud, should be emphasized, and every effort should be made to restore it

Seventy-five years ago a cultist might easily obtain a charter for a medical school and incorporate his ideas in as little or as much medicine as he saw fit. As this is no longer possible, he seeks recognition for his cult by his own separate board of registration which will approve his own schools.

The basis for his claim is the provincial and ignorant assertion that since he uses no drugs he is not practicing medicine. By repeating this false statement over and over again he persuades those minded like himself, in and out of legislative halls.

There is a tendency for the cultist schools to become more and more like standard schools of medicine. One of the arguments set forth in favor of the recently enacted law that postpones the effective date of the activity of the Approving Authority was that not sufficient time was given by the original statute for schools of osteopathy to reach the approved standards. Such assimilation to standard schools of medicine appears to a disinterested person to be a move in the right direction. But among osteopathic physicians there are some partisans with keener insight than the average who think it is the beginning of the end and who have issued warnings against the tendency. This assimilation is a concession that osteopathy is not enough, and a recognition that osteopathy is a part of the practice of medicine, and such concession and recognition inevitably lead to the view that osteopathy at its best can be regarded as only one possible method of treatment among the many resources of the healing art. What the residue, if any, of osteopathic procedures will be, one cannot say. Perhaps some form of "manipulative surgery" will include whatever there is of permanent good. But its theory as to the cause of disease has never received any scientific support. The chiropractic schools—at least some of them—are improving so that in certain respects they resemble the poorer schools of medicine seventy-five years ago, the names of which are now forgotten. Why

go back to those obsolete standards of medical education?

The secret of the power of the cult is the esoteric quality of its dogma. As soon as there is acknowledged the necessity for aught else,—as by approximating its curriculum to that of the standard medical school,—the corrosive poison has entered its system and, as a matter of experience, can never be eliminated.

Just what will come from the study proposed by the resolve no one can foretell, but anything that will throw more light on the growth, development and actual worth of osteopathy and chiropractic and their schools should be welcomed.

HUNTINGTON MEMORIAL HOSPITAL

THE annual report of the Collis P. Huntington Memorial Hospital calls renewed attention to the excellent work being done by the oldest special cancer hospital in the community. Although limited in its number of beds, its active outpatient department and above all the importance of its work have done much to forward the cause of cancer control.

The hospital is in no small part a monument to the vision and unremitting work of the late Dr. Robert B. Greenough, whose clear insight of the need for both fundamental research in cancer and the development of methods of diagnosis and therapy, as well as training younger members of the medical group in the knowledge of cancer, has made possible the high state of development of cancer control in Massachusetts.

The outstanding advance at the hospital in the past year has been the installation of the new Van de Graaff-Trump supervoltage x-ray generator, which enables the hospital to treat patients with the highest effective x-ray voltage ever generated for therapeutic purposes. The machine operates routinely at 1,200,000 volts, roughly equivalent to the amount of radiation that might be obtainable from 2000 grams of radium element. While it is too soon to evaluate the therapeutic results, the work will be followed with great interest by all those working in the field of cancer.

CASE HISTORY No. 77. PREMATURE PARTIAL
SEPARATION OF THE PLACENTA

Mrs. B. G., a twenty-two-year-old primipara in the thirtieth week of her pregnancy, was walking along the street when she started to flow and flowed enough to saturate her clothing. She went to her physician's office immediately.

Her family history was negative. Her tonsils had been removed as a child and her appendix had been taken out ten years before. She had a history of healed tuberculosis. There was no history of diabetes, scarlet fever, rheumatic fever or malignant disease.

Catamenia began at thirteen, with a regular twenty-eight-day cycle, lasting three or four days without pain. Her last period was late in July, making her due for delivery early in May.

Physical examination in October, early in her pregnancy, showed a well-developed and nourished young woman. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The blood pressure was 120 systolic, 60 diastolic. Vaginal examination showed the cervix posterior and the fundus anterior.

She was seen routinely throughout her pregnancy, which was normal in every respect until the above-mentioned bleeding. Physical examination at this time, March 16, showed the uterus very irritable as though she were going into labor. It was somewhat spastic but did relax at times. The fetal heart was heard. The diagnosis of partial separation of the placenta was made and she was sent at once to the hospital. A previous examination on March 1 showed a high-breech presentation. A rectal examination at this time ruled out a placenta previa. Upon arrival at the hospital her blood was matched and cross-matched with her husband's blood which was found to be compatible. In view of the fact that the chance of the baby's survival was so small because of its prematurity, it seemed wise to treat her conservatively.

There was practically no bleeding after hospitalization, although the uterine contractions kept up and it was thought that she was going into labor. These continued off and on for about a week and then subsided. During this time there was no bleeding. She was kept in the hospital until April 11. Three days before she was allowed to go home a vaginal examination was done under aseptic conditions. It showed the cervix not flat and a breech well in the lower segment, no placenta was felt. No attempt was made to put the finger through the cervix.

She was seen at home on April 20, at which time her blood pressure was 118 systolic, 60 diastolic. A specimen of urine obtained at this time showed a trace of sugar and of albumin.

She started in labor about 6 p. m., April 20. A rectal examination at 6:45 p. m. was unsatisfactory. A vaginal examination at 8:30 p. m. showed the cervix taken up and thin and dilated about three fingers, the breech was presenting. A normal, double footling, SRA position, extraction was performed at 10:30 p. m. The child, a female, weighed 5 lb., 10 oz., and appeared in good condition. The placenta showed an area of degeneration about 7.5 cm. square, the seat of the previous bleeding. There was no bleeding after delivery, and her entire convalescence was uneventful.

Comment. The treatment of partially separated placentas before thirty-two weeks should always be conservative because the risk to the mother of abdominal delivery is not justified. As a matter of fact, most completely separated placentas at this period should be treated conservatively. If this condition arises four weeks later and the bleeding keeps up and labor does not result, then cesarean section becomes justifiable because the chance of the baby's survival at this time is excellent. In this individual case it was believed that the separation of the placenta was not complete, that labor was imminent and that the baby had just as good a chance, even though it was small, of survival after vaginal delivery as it would have had by section. There was no justifiable excuse for subjecting the mother to the added dangers of a section.

Prolonged hospitalization before viability in the absence of further bleeding is the ideal treatment. Intelligent procrastination—leaving the vagina entirely alone—in the absence of further bleeding until viability is well assured is not only justifiable but advisable, for many babies will undoubtedly be saved by this method. Routine immediate vaginal examinations before viability are contraindicated in cases of this type.

A series of selected case histories by members of the section will be published weekly.

Comments and questions by subscribers are solicited and will be discussed by members of the section.

TUBERCULOSIS*

In spite of the encouraging decline in tuberculosis, the pulmonary form of the disease is still a major public-health problem. It is one of the chief causes of death in early adult life.

The earlier the diagnosis is made, the greater the chance of stopping the disease by treatment. Early diagnosis is also of great moment to the patient's family and the community in diminishing the danger of well people getting the disease.

If you have a persistent cough with or without fever, or if you have night sweats, loss of appetite and loss of weight, if you have an attack of pleurisy or if you spit up blood, you should consult your doctor at once. In addition to a physical examination, he will want the sputum examined and an x-ray of the chest.

Financial considerations need not stand in the way. The State Department of Public Health has a diagnostic laboratory at the State House, and laboratories are maintained by local boards of health in many communities where sputums sent by physicians are examined for tubercle bacilli free of charge.

Facilities are fortunately available throughout the State for the x-ray examination of patients unable to pay and for those who have been living with them. Such persons may be referred by physicians to diagnostic outpatient departments or consultation clinics maintained by the state or county sanatoriums, or to certain tuberculosis diagnostic clinics maintained by local boards of health.

It is not to be expected, however, that in any large proportion of cases the disease will be recognized in its early stages, or proper treatment started, or measures taken to prevent spread of infection in the family and the community unless you realize (1) that in the early stages of the disease there may be no suggestive symptoms or physical signs, (2) that an early diagnosis may be possible only by x-ray examination, (3) that there is a high percentage of infection among those exposed to the disease in the family, (4) that an x-ray examination should be made of all family contacts of a patient with tuberculosis, and (5) that the investigation of school children for tuberculosis is an important means of prevention and control of the disease.

The investigation of school children, known as the Ten Year Program, was initiated by Dr. Henry D. Chadwick, our very capable Commissioner of Public Health. School children were examined on a statewide scale for the ten years following June, 1924. In the course of this survey of nearly 1,000,000 children in the investigated schools, 400,000, or 40 per cent, were tested with tuberculin and 100,000 who reacted to the test were x-rayed.

Results of far reaching importance for Massachusetts and other communities were obtained in the course of this investigation. It demonstrated the prevalence of tuberculosis in children and the significance of family contact as a source of contagion. It furnished information of importance for the prevention and control of tuberculosis in the community.

In accordance with the original plan, the State Department of Public Health terminated the Ten Year Program in June, 1934. Since then, the routine examination of school children has been carried out through the services of the state and county sanatoriums and by the State Department of Public Health in certain places where the sanatoriums are unable to furnish such service.

Facilities for the routine investigation of school children

*A. Green Lights to Health, broadcast given by Dr. Frederick T. Lord on Wednesday, June 8, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

are by these means available in most communities in the State. In Boston during the past year, children in the parochial schools have been investigated by the Boston Health Department.

In the examination of school children for tuberculosis, a change has been made from the investigation annually of the seventh, ninth and eleventh grades. Beginning with the school year, 1937-38, examinations have been made of children in the high school grades. This has the advantage of enabling the examiners to investigate a larger number of children in one school at one time and to return to the same school when others have taken the place of children already investigated.

Owing to the usual absence of symptoms and physical signs with tuberculosis in childhood, it is only by x-ray examination that the disease can be discovered. Children whose parents sign the request slips are first tested with tuberculin and an x-ray examination is made of the children who react to the test.

* * *

Q. Dr. Lord, will you explain why it is desirable first to test the children with tuberculin and to x-ray only those who react to the test? Would it not be easier to x-ray all the children?

A. Yes, Mr. Strawson, it would be easier to x-ray all the children, but much more expensive. The test with tuberculin is a relatively simple and inexpensive procedure. The cost of the x-ray examination amounts to about \$1.00 per child.

Sensitivity to tuberculin is acquired in the course of infection with tubercle bacilli and is limited to the subjects of such infection. Reactions to tuberculin serve to reveal those children who have been infected with tubercle bacilli. This is spoken of as a screening process.

Q. How is the tuberculin test performed?

A. Until recently the children were tested by what is known as the scratch test in which the tuberculin is scratched into the superficial layers of the skin. Recently the test has been made by injecting a very small amount of this substance into, not under, the skin.

Q. Is it a painful process?

A. Only a slight prick from the introduction of a fine needle into the skin.

Q. What proportion of the children may be expected to react to tuberculin?

A. The proportion varies in different communities. In general, about 30 per cent of the high school students may be expected to react.

Q. Does the reaction to tuberculin indicate that the child is in a serious condition?

A. Not at all! The reaction to tuberculin means that there has been exposure to tubercle bacilli. The resulting infection is usually inactive and unimportant. A positive skin test to tuberculin in the absence of other manifestations is of little or no importance.

Q. What is likely to be found on x-ray examination of the children who react to tuberculin?

A. In the high schools, about 1 in 80 of the children tested may be expected to have x-ray evidence of what is called the first infection, or childhood type, of tuberculosis, with involvement of the lung and the lymph nodes about the larger air passages. In about 1 in 700 of the children tested, the adult type of pulmonary tuberculosis will be found.

Q What is meant by the adult type of tuberculosis in children?

A. The adult type of tuberculosis is a reinfection in an already infected individual. The disease is likely to be in the upper parts of the lung and is prone to undergo softening, ulceration and cavity formation.

Q Is there a difference in the importance of these two forms of the disease in children—the childhood and the adult type?

A In the high schools, the finding of at least 8 cases of the childhood type to 1 of the adult type makes the former the most important group so far as numbers go.

The two forms of the disease are, however, quite different from the point of view of seriousness.

The childhood type of the disease is usually mild and the outlook favorable. Its discovery is to be regarded as a safeguard in the opportunity afforded to prevent further infection, for instruction regarding exercise, rest and diet and for further x ray examinations. It is to be expected that, in consequence, further progress of the disease will be prevented in many cases, with resulting saving of life and the avoidance of an expensive illness. On the whole, however, because of its usual benign course the most important advantage to be derived from the discovery of the childhood type is the opportunity to find a source of infection through the investigation of family contacts.

The adult type of tuberculosis in children is serious and the outlook poor. Its discovery affords the opportunity for the institution of treatment, the elimination of a source of danger to others by removal of the child from school and the examination of family contacts.

Q In what proportion of high school children is parental consent given for the examination?

A During the last four years of the Ten Year Program, of about 88,000 children in the investigated high schools, permission was granted for the testing of only a little over half the children.

Q As the examination is paid for out of tax money and is of advantage to the children and their families, why is the proportion of consents so low?

A As the information obtained may be lifesaving and lead to the avoidance of an expensive illness, the explanation must be that the purpose and importance of the examination is not fully understood.

Q With respect to examination of family contacts, does this mean that the family contacts of all the children who react to tuberculin should be examined?

A. No. It is only the family contacts of the few children who are found to have tuberculosis by x ray examination. In addition, the importance should be emphasized of the x ray examination of all household contacts of tuberculous patients in the state, county, municipal and private sanatoriums and in the practice of physicians.

As an indication of the importance of the examination of family contacts, it may be noted that during a period of four years, practically 90 per cent of the family contacts of patients at one of the county sanatoriums were examined with the finding of the disease in over 20 per cent and active pulmonary involvement in about 8 per cent. By this means, more patients in the early and consequently favorable stages were admitted to this sanatorium than by all applications through the usual channels.

Investigation for tuberculosis should be made of grade and high school teachers, students entering the state teachers colleges, nurses in hospitals at the time of enrollment, medical students, hospital interns, nursemaids and domestic help where there are children. Investigation should

also be made of all people known to have diabetes as they are especially susceptible to tuberculosis.

Q In patients in whom an early diagnosis is made, are the results of treatment favorable?

A. The early recognition of pulmonary tuberculosis may be expected to be followed by rapid subsidence of symptoms, but physical activities even under the most favorable circumstances must be very largely restricted at least for months and permanent arrest of the disease can hardly be expected within a number of years.

Q Is there hope of recovery when the disease is beyond the early stages?

A Late recognition diminishes the chance for recovery, but much may still be done and many lives saved. It may be necessary, however, to resort to the use of more radical measures in the treatment of such cases. Important advances in treatment have been made in the development of methods for putting the affected part of the lung at rest. These methods are spoken of as collapse therapy, and the procedures are technically known as artificial pneumothorax, phrenic-nerve operations and thoracoplasty. This surgical attack is one of the most important of the recent advances in the treatment of old fashioned consumption, or what we now call pulmonary tuberculosis.

DEATHS

BREWSTER—MARY JONES BREWSTER, M.D., of Wellesley, died June 9. She was in her seventy sixth year.

Born at Brookfield, she was graduated from Wellesley College in 1883 and from the Women's Medical College of Pennsylvania in 1892.

Dr Brewster was formerly resident physician of Smith College and had served as social service head of the cotton mills at Lagrange, Georgia. Formerly a fellow of the Massachusetts Medical Society she had been retired for some time.

A sister and a brother survive her.

EVELETH—SAMUEL EVELETH, M.D., of 32 Pleasant Street, Marblehead, died June 14. He was in his fifty sixth year.

Born in Marblehead, he graduated from Amherst College in 1904 and received his degree from the Harvard Medical School in 1908. For thirty years he had been a practicing physician in Marblehead and was a trustee of the Mary Alley Hospital and a member of the staff of the Salem Hospital. Dr Eveleth was a fellow of the Massachusetts Medical Society and the American Medical Association and was a member of the North Shore Medical Society.

A sister and a brother survive him.

TASKER—FRANK E. TASKER, M.D., of West Acton, died June 19, at his home. He was in his seventy fifth year.

Born in Northwood, New Hampshire, he was graduated from Dartmouth Medical School in 1893. Dr Tasker was the oldest physician in Acton both in service and age, having practiced there for forty four years. He was the chairman of the Board of Health.

Dr Tasker was a member of the American Medical Association and a fellow of the Massachusetts Medical Society.

A half brother survives him.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATHS

SMITH—FRANK A. SMITH, M.D., died in Florida on April 24 at the age of eighty-three. He was for many years a practicing physician in Lebanon. In 1932 Dr. Smith was made an affiliate member of the New Hampshire Medical Society.

THERIAULT—JOSEPH THERIAULT, M.D., aged seventy-eight, died May 9 in Montreal, Province of Quebec. He was born in Joliette, Province of Quebec, but moved from there to Laconia and later went to Concord, where he was a practicing physician for thirty-five years.

He is survived by two brothers, Eylsses Theriault, of Montreal, and Philias Theriault, of Los Angeles.

DISTRICT SOCIETY NEWS

The Grafton County Medical Society met at the Littleton Hospital, on April 28, as guests of the staff. Drs. A. F. Erdmann, of Lisbon, Montfort Haslam, of Littleton, and Frank Seligson, of Glencliff, were elected to membership in the society. The program was a symposium on undulant fever, discussion being contributed by Drs. Pickwick, Bogle and Eckels. Dr. Eckels showed a case of cardiospasm of unusual interest in that gastrotomy had been required, but the patient was eventually able, as a result of gradual esophageal dilatation, to take solid food by mouth. The patient, who has been trained to use bougies himself, gave a demonstration for the society.

MISCELLANY

NOTE

Dr. Stanton J. Ten Broeck, of Orange, Massachusetts, was recently tendered a reception by his many friends on the occasion of completing forty-five years' service to the residents of Orange and the surrounding territory.

Born in Hillsdale, New York, Dr. Ten Broeck graduated from New York University Medical College and settled in Orange. He is director of the Orange National Bank and vice president of the Orange Savings Bank, and has been a fellow of the Massachusetts Medical Society since 1893.

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital, April 21, Dr. Henry A. Christian presiding. The first paper of the evening was presented by Dr. Emil Goetsch, professor of surgery in the Long Island College of Medicine, Brooklyn, who spoke on the subject "Adrenalin Sensitivity in Hyperthyroidism."

Dr. Cannon previously had shown by animal experimentation that when the thyroid gland is activated or when thyroid extract is administered, the sympathetic nervous system is rendered hypersensitive to injected adrenalin. Accordingly, Dr. Goetsch early believed that human beings suffering from hyperthyroidism should show a similar increased response to adrenalin, with an accentuation of the symptoms of thyroid hyperactivity. He found that 0.5 cc. of adrenalin administered subcutaneously to a person with hyperthyroidism caused characteristic responses such as nervousness, apprehension, restlessness, tremor, vasoconstriction followed by flushing, perspiration, rise in blood

pressure, increase in pulse pressure and pulse rate, and a acceleration in respiratory rate. Such effects persisted to from one to one and a half hours. Normal individuals usually experienced no symptoms from the administration of this amount of adrenalin. The reactions of persons with neurasthenia and Addison's disease were only minimal and very transient. The degree of response in patients with hyperthyroidism was found to vary in intensity with the degree of severity of the disease. Dr. Goetsch developed a test to differentiate hyperthyroidism and various nervous disorders, using the response to a standard dose of 0.5 cc. of adrenalin as an index. Since the development of the method for determination of the basal metabolic rate, this adrenalin sensitivity test has not been used for diagnostic purposes except in cases of apparently non-toxic adenomatous goiter in which the metabolic rate may not be elevated. In such patients there is a characteristic clinical syndrome due to the action of the adenomatous goiter, the presence of which can be confirmed by a positive adrenalin sensitivity test. In such instances the adrenalin test has been more useful as a criterion of thyroid disease than the metabolic rate.

He further stated that patients in thyroid storm exhibit in a magnified degree all the symptoms observed following injection of adrenalin, and considered it probable that the storm is caused, in large part, by the effect of the patient's own adrenine secreted in excessive amounts. Although administration of potassium iodide or Lugol's solution to hyperthyroid patients reduced the basal metabolic rate, it did not necessarily decrease the fundamental hypersensitivity to adrenalin. It was believed that further investigations into this subject might eventually be of aid in decreasing deaths due to thyroid storm.

Dr. Francis G. Blake, Sterling Professor of Medicine in the Yale University School of Medicine, delivered the second paper, on the subject "The Value of Antitoxin in Scarlet Fever."

Preliminary investigations on the use of scarlet fever antitoxin gave rise to divergent opinions as to its value. Some persons held that its usefulness was outweighed by frequent anaphylactic reactions, and by the high incidence of serum sickness following its administration. Many felt that no strong evidence had been produced to show that it decreased or controlled the complications of the disease. Other investigators (of which Dr. Blake was one) believed that the antitoxin was of definite value in the toxic stage of the disease and was also of value in decreasing septic complications in incidence and severity.

Some of the divergent opinions arose from the use of the serum in the late stages of the disease after the rash had faded—a time when antitoxin is of no value. Other false impressions were given by the inadequate standardization of many of the serums on the market, some of which were extremely weak in potency. Another reason for the divergence of opinion was the too frequently held concept of the minimum therapeutic dose. Higher doses of antitoxin should be used than those usually recommended.

Dr. Blake discussed observations made on 464 cases seen between the years 1924 and 1937. All these cases were admitted and treated during the first week of their disease. They were classed as mild if their temperature was under 102°F (per rectum) and they had only slight tonsillitis or pharyngitis. Extremely severe cases had a temperature between 103 and 107°F, extreme pharyngitis, active delirium or coma. Severely septic cases were complicated by adenitis, otitis media, meningitis, and so forth. The majority of these cases received between 14,000 and 40,000 units of antitoxin. The mild cases are no longer given serum. The extreme cases receive as much

as 60,000 units. The serum is usually given intramuscularly. Approximately 35 per cent of these cases still develop serum reactions, but only 10 per cent are severe.

Evaluation of the results of treatment with antitoxin is particularly difficult due to the self limitation of the disease and because of its dual nature. Evaluation can be approached in two ways (1) objective study of phenomena occurring abruptly following antitoxin administration, (2) comparison of complications arising in treated and untreated cases

1 *Influence of antitoxin on toxic phenomena* The course of the toxemia is paralleled by the course of the rash, and assays of the amount of toxin in the blood have proved this point. The amount of toxin in the blood varies within wide limits, however, in some individuals being as low as 0.25 unit per cubic centimeter, and in others as high as 300 units per cubic centimeter. The toxemia increases during the first three days of the disease, and then subsides in the usual case. In septic cases the toxemia is apt to be more severe and often lasts for seven days, but then subsides, even though the sepsis continues. Antitoxin to be effective must cause a blanching of the rash when injected subcutaneously in high dilution. Study of cases treated with antitoxin showed that it produced rapid fading of the rash, and an abrupt fall in temperature. The antitoxin was found to neutralize the toxin in the blood, and the appearance of antitoxin could be demonstrated in the blood following the intramuscular injection.

2 *Effect of antitoxin on incidence and severity of complications* In an occasional case with severe sepsis for example, meningitis, antitoxin produced marked improvement, although many similar cases showed no benefit. Of 464 cases treated with antitoxin 16 per cent developed complications or sequelae subsequent to administration of antitoxin. In a control group of 434 untreated cases 34 per cent developed complications or sequelae. The treated group was favored because of the greater number of adults included. On the other hand the distribution according to severity strongly favored the untreated group as did the fact that only 20 per cent of the untreated as opposed to 47 per cent of the treated cases were septic on admission. Cases receiving treatment on the fourth to the seventh day did not show such a marked decrease in incidence of complications as did those treated on the first to the third day. On the basis of his experience Dr Blake is satisfied that antitoxin has value in reducing the incidence of subsequent complications and sequelae provided it is used early in the course of the disease. Therefore he treats all moderately severe to severe toxic cases with antitoxin as soon as possible.

Dr Blake does not believe that the use of a few cubic centimeters of convalescent serum is of value, since such serum contains only from 10 to 20 units of antitoxin per cubic centimeter, and best results are obtained with an average of 20,000 units of antitoxin. In cases extremely sensitive to horse serum, transfusion of from 400 to 600 cc. of whole blood is often of value.

During the discussion Dr Blake stated that the effect of sulfanilamide on the incidence and severity of complications of scarlet fever has not yet been properly evaluated. This drug probably exerts no influence on the toxic effects of the disease.

Meeting will be held at 11 a. m. on July 21

BOOKS RECEIVED FOR REVIEW

Embryonic Development and Induction Hans Spemann. 401 pp. New Haven: Yale University Press, 1938. \$5.00

The Romance of Proctology Charles E. Blanchard. 284 pp. Youngstown: Medical Success Press, 1938. \$4.50

Cause and Prevention of Disease William H. Perkins. 713 pp. Philadelphia: Lea & Febiger, 1938. \$7.50

The New International Clinics: Original contributions, clinics, and evaluated reviews of current advances in the medical arts Edited by George M. Piersol. Volume 2, N S I. 315 pp. Philadelphia, Montreal, New York: J. B. Lippincott Company, 1938. \$3.00

NEW HAMPSHIRE MEDICAL SOCIETY

DEATHS

SMITH—FRANK A. SMITH, M.D., died in Florida on April 24 at the age of eighty three. He was for many years a practicing physician in Lebanon. In 1932 Dr Smith was made an affiliate member of the New Hampshire Medical Society.

THERIAULT—JOSEPH THERIAULT, M.D., aged seventy-eight, died May 9 in Montreal, Province of Quebec. He was born in Joliette, Province of Quebec, but moved from there to Laconia and later went to Concord, where he was a practicing physician for thirty five years.

He is survived by two brothers, Eylsses Theriault, of Montreal, and Philias Theriault, of Los Angeles.

DISTRICT SOCIETY NEWS

The Grafton County Medical Society met at the Littleton Hospital, on April 28, as guests of the staff. Drs A. F. Erdmann, of Lisbon, Montfort Haslam, of Littleton, and Frank Selgson, of Glencliff, were elected to membership in the society. The program was a symposium on undulant fever, discussion being contributed by Drs Pickwick, Bogle and Eckels. Dr Eckels showed a case of cardiospasm of unusual interest in that gastrostomy had been required, but the patient was eventually able, as a result of gradual esophageal dilatation, to take solid food by mouth. The patient, who has been trained to use bougies himself, gave a demonstration for the society.

MISCELLANY

NOTE

Dr Stanton J. Ten Broeck, of Orange, Massachusetts, was recently tendered a reception by his many friends on the occasion of completing forty five years service to the residents of Orange and the surrounding territory.

Born in Hillsdale, New York, Dr Ten Broeck graduated from New York University Medical College and settled in Orange. He is director of the Orange National Bank and vice president of the Orange Savings Bank, and has been a fellow of the Massachusetts Medical Society since 1893.

REPORTS OF MEETINGS

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held at the Peter Bent Brigham Hospital, April 21, Dr Henry A. Christian presiding. The first paper of the evening was presented by Dr Emil Goetsch, professor of surgery in the Long Island College of Medicine, Brooklyn, who spoke on the subject "Adrenalin Sensitivity in Hyperthyroidism."

Dr Cannon previously had shown by animal experimentation that when the thyroid gland is activated or when thyroid extract is administered, the sympathetic nervous system is rendered hypersensitive to injected adrenalin. Accordingly, Dr Goetsch early believed that human beings suffering from hyperthyroidism should show a similar increased response to adrenalin, with an accentuation of the symptoms of thyroid hyperactivity. He found that 0.5 cc. of adrenalin administered subcutaneously to a person with hyperthyroidism caused characteristic responses such as nervousness, apprehension, restlessness, tremor, vasoconstriction followed by flushing, perspiration, rise in blood

pressure, increase in pulse pressure and pulse rate, and acceleration in respiratory rate. Such effects persisted for from one to one and a half hours. Normal individuals usually experienced no symptoms from the administration of this amount of adrenalin. The reactions of persons with neurasthenia and Addison's disease were only minimal and very transient. The degree of response in patients with hyperthyroidism was found to vary in intensity with the degree of severity of the disease. Dr Goetsch developed a test to differentiate hyperthyroidism and various nervous disorders, using the response to a standard dose of 0.5 cc. of adrenalin as an index. Since the development of the method for determination of the basal metabolic rate, this adrenalin sensitivity test has not been used for diagnostic purposes except in cases of apparently non-toxic adenomatous goiter in which the metabolic rate may not be elevated. In such patients there is a characteristic clinical syndrome due to the action of the adenomatous goiter, the presence of which can be confirmed by a positive adrenalin sensitivity test. In such instances the adrenalin test has been more useful as a criterion of thyroid disease than the metabolic rate.

He further stated that patients in thyroid storm exhibit in a magnified degree all the symptoms observed following injection of adrenalin, and considered it probable that the storm is caused, in large part, by the effect of the patient's own adrenine secreted in excessive amounts. Although administration of potassium iodide or Lugol's solution to hyperthyroid patients reduced the basal metabolic rate, it did not necessarily decrease the fundamental hypersensitivity to adrenalin. It was believed that further investigations into this subject might eventually be of aid in decreasing deaths due to thyroid storm.

Dr Francis G. Blake, Sterling Professor of Medicine in the Yale University School of Medicine, delivered the second paper, on the subject "The Value of Antitoxin in Scarlet Fever."

Preliminary investigations on the use of scarlet fever antitoxin gave rise to divergent opinions as to its value. Some persons held that its usefulness was outweighed by frequent anaphylactic reactions, and by the high incidence of serum sickness following its administration. Many felt that no strong evidence had been produced to show that it decreased or controlled the complications of the disease. Other investigators (of which Dr Blake was one) believed that the antitoxin was of definite value in the toxic stage of the disease and was also of value in decreasing septic complications in incidence and severity.

Some of the divergent opinions arose from the use of the serum in the late stages of the disease after the rash had faded—a time when antitoxin is of no value. Other false impressions were given by the inadequate standardization of many of the serums on the market, some of which were extremely weak in potency. Another reason for the divergence of opinion was the too frequently held concept of the minimum therapeutic dose. Higher doses of antitoxin should be used than those usually recommended.

Dr Blake discussed observations made on 464 cases seen between the years 1924 and 1937. All these cases were admitted and treated during the first week of their disease. They were classed as mild if their temperature was under 102°F (per rectum) and they had only slight tonsillitis or pharyngitis. Extremely severe cases had a temperature between 103 and 107°F, extreme pharyngitis, active delirium or coma. Severely septic cases were complicated by adenitis, otitis media, meningitis, and so forth. The majority of these cases received between 14,000 and 40,000 units of antitoxin. The mild cases are no longer given serum. The extreme cases receive as much

THE RELATION OF THE PHYSICIAN TO INDUSTRY

MRS. EMMA SANBORN TOUSANT*

BOSTON

COMPENSATION legislation in the United States, after some twenty-five years of application, appears to be securely anchored in our industrial system, and because of the scope of the present law in the many states where it is in force, a greater opportunity than ever before is open to the medical profession to contribute to the welfare of industry. Many other forms of social legislation have sprung up in the last few years and are equally secure in our industrial world. It is no longer claimed that social legislation is on trial, and compensation insurance should be made as compulsory as old-age-assistance compensation and unemployment-insurance compensation. It is interesting to examine some of the policies of administration that have broken down opposition and gradually brought opposing factions to a sympathetic support of the fundamental principles upon which the legislation was founded, the basic one being that industry should bear the burden of the cost of all injuries to its workmen when these are attributable to hazards inherent in employment and due to its conditions. In Massachusetts, the fundamental purpose of the Workmen's Compensation Act is to give to the employee fair valuation for the loss suffered and to restore him to industry with the least possible delay. This fundamental purpose has been hampered, first, by the limitations in the early provisions of the law relating to medical treatment, and secondly, by the abuses and deficiencies that have grown up under the later provisions, together with inadequate diagnosis and treatment of many conditions by the medical profession. The profession in general has been an active force in fostering and sustaining the true spirit of the law. Its interest and co-operation have always been and still are essential to the success of the administration of the Workmen's Compensation Act.

Section 30 of Chapter 152 of the General Laws

Presented at the Fall meeting of the Massachusetts Medico-Legal Society
October 6, 1937
Chairman, Mr. C. Bussett, Industrial Accident Board

relates to medical treatment, and a résumé of the original law and its amendments may lead to a better understanding of the interpretation and rulings made by the Industrial Accident Board since the Workmen's Compensation Act became effective July 1, 1912.

The act provided that during the first two weeks after the injury "the association," which was then the "insurer," should furnish reasonable medical and hospital expenses and medicine when needed. The word "furnish" was interpreted by the Supreme Judicial Court to mean that the insurer should arrange in advance for such treatment in the ordinary case or provide that someone be at hand to do so. In other words, the statute imposed an obligation upon the insurer to furnish reasonable medical attention, but did not make it mandatory that the employee accept such attention exclusively. He could, if he wished, secure medical attention of his own selection but at his own expense.

The beneficial result of these early provisions was that the physicians furnished by the insurer were able to decide the true medical status of the case, because as a practical problem the insurer employed physicians who stood out prominently as surgeons or diagnosticians along industrial medical lines.

The defective feature of this early provision was its failure to accomplish the employee's restoration to industry because of the legal limitations precluding adequate medical treatment. This was an injustice not only to the injured workman but to the physician treating him. These inadequate provisions defeated the salvaging of the employee.

As a second step toward industry's bearing the burden of industrial injuries, provision was made by the legislature to enable the employee to select his own physician. The reasonable cost of the services had to be paid for by the insurer, and these provisions extended the time and scope of the treatment. Where the treatment was ren-

BOOK REVIEWS

Workbook on Elementary Diagnosis for Teaching Clinical History Recording and Physical Diagnosis Logan Clendening 167 pp St. Louis The C. V. Mosby Company, 1938 \$1.50

With his usual flair for discovering new ways of presenting old and significant facts, Dr. Clendening has evolved a laboratory manual for the young student of elementary diagnosis which stands midway between the paper-covered pamphlet supplied by hospitals and medical schools for the guidance of clinical clerks and the usual textbook of physical diagnosis. Several of the recently published textbooks of physical diagnosis have been characterized by eye appeal through excellent photographic illustrations at the expense of careful accuracy in the text. It is a pleasure to be able to praise the quality of Clendening's illustrations (pen drawings from photographs) and at the same time acknowledge the reliability of his text. Achievement of the latter is aided by abundant references to the citations from the works of the original discoverers of common physical signs—a custom which is happily growing among textbook authors. The reduction in price (from \$3.00 to \$1.50) is added justification for advising the second year medical student that this is a book to be placed on his 'must buy' list.

The New International Clinics Original contributions, clinics, and evaluated reviews of current advances in the medical arts Edited by George M. Piersol Volume I, N. S. 1 322 pp Philadelphia, Montreal, New York J. B. Lippincott Company, 1938 \$3.00

This quarterly volume of a periodical published since 1891 appears this year under its new editor George Morris Piersol. The purpose of the *International Clinics* from the first was to serve as a postgraduate course in medical instruction, for those unable to attend courses at the bedside, by publishing carefully edited stenographic reports of lectures or discussions in wards or amphitheatres, only at times were especially prepared original articles included. That they filled a need is indicated by the popularity attained and by the appearance of other similar publications.

The *New International Clinics*, however, has lost the distinctiveness of its predecessor. It contains seventeen excellent original contributions covering many aspects of medicine and surgery by eminent men throughout the country, but there are only thirty pages of clinics.

George R. Minot is the Boston representative on the editorial board, and there are original papers by Harold Jeghers, William H. Robey and Donald S. King of this city.

A Dissertation on Acute Pericarditis, 1836 Oliver W. Holmes 39 pp Boston Welch Bibliophilic Society, 1937

A hitherto unknown manuscript which Holmes prepared as his thesis for graduation from the Harvard Medical School, in 1836, has been brought to light among the Holmesiana at the Boston Medical Library and published by the Welch Bibliophilic Society. The text presents a study made by him upon a series of 11 cases of acute pericarditis which he observed while in attendance upon the wards of a Parisian hospital during the years 1833-35. Before going abroad he had taken two courses at a private medical school in Boston and upon his return, late in 1835, he obtained his medical degree from Harvard University.

The date at the end of the dissertation is January 12, 1836, and in the last paragraph he states that he had only three days in which to prepare the thesis, having recourse only to his own library and to the cases he had tabulated two years before in Paris, where he saw the material with Louis and Andral, his preceptors. The record is interesting as indicative of the methods of research in vogue at that time, these were largely clinical, of course, in a condition of this sort, but were supplemented by a certain amount of postmortem material, the nature and significance of which were only just beginning to be appreciated by the brilliant group of French physicians headed by Andral, Laennec, Chomel and Louis. The petty rivalries engendered by the desire to receive credit for advancement of the knowledge of disease are much in evidence—happily more so than is true of the present time.

Man Bread and Destiny The story of man's food C. C. Furnas and S. M. Furnas 364 pp Baltimore The Williams & Wilkins Company, 1937 \$3.00

Beginning with the evolutionary stages leading to present-day human dietetic practices, this book attempts to show the influences which food has exerted in the development of civilization, and in subsequent chapters explains the part played in nutrition by carbohydrates, fats, proteins, minerals and vitamins. Adequate space is given to a discussion of each of these essential constituents of a wholesome diet, with explanations of the danger incident to the omission of any one or more of them.

Enough space is given to the physiologic chemistry of nutrition to enable the lay reader to understand how the vital forces of the body are maintained. The section devoted to the vitamins makes clear the present-day knowledge pertaining to the role of these indispensable elements. In addition to the recital of facts relating to nutrition and the associated disease problem, advice concerning the economics of food supplies is presented.

This is an unusually interesting book in addition to the factual data the authors have a sense of humor and have introduced many historical references and personal opinions which help the reader to profit by the information set forth.

THE RELATION OF THE PHYSICIAN TO INDUSTRY

MRS EMMA SANBORN TOUSANT*

BOSTON

COMPENSATION legislation in the United States, after some twenty-five years of application, appears to be securely anchored in our industrial system, and because of the scope of the present law in the many states where it is in force, a greater opportunity than ever before is open to the medical profession to contribute to the welfare of industry. Many other forms of social legislation have sprung up in the last few years and are equally secure in our industrial world. It is no longer claimed that social legislation is on trial, and compensation insurance should be made as compulsory as old-age-assistance compensation and unemployment-insurance compensation. It is interesting to examine some of the policies of administration that have broken down opposition and gradually brought opposing factions to a sympathetic support of the fundamental principles upon which the legislation was founded, the basic one being that industry should bear the burden of the cost of all injuries to its workmen when these are attributable to hazards inherent in employment and due to its conditions. In Massachusetts, the fundamental purpose of the Workmen's Compensation Act is to give to the employee fair valuation for the loss suffered and to restore him to industry with the least possible delay. This fundamental purpose has been hampered, first, by the limitations in the early provisions of the law relating to medical treatment, and secondly, by the abuses and deficiencies that have grown up under the later provisions, together with inadequate diagnosis and treatment of many conditions by the medical profession. The profession in general has been an active force in fostering and sustaining the true spirit of the law. Its interest and co-operation have always been and still are essential to the success of the administration of the Workmen's Compensation Act.

Section 30 of Chapter 152 of the General Laws

relates to medical treatment, and a résumé of the original law and its amendments may lead to a better understanding of the interpretation and rulings made by the Industrial Accident Board since the Workmen's Compensation Act became effective July 1, 1912.

The act provided that during the first two weeks after the injury "the association," which was then the "insurer," should furnish reasonable medical and hospital expenses and medicine when needed. The word "furnish" was interpreted by the Supreme Judicial Court to mean that the insurer should arrange in advance for such treatment in the ordinary case or provide that someone be at hand to do so. In other words, the statute imposed an obligation upon the insurer to furnish reasonable medical attention, but did not make it mandatory that the employee accept such attention exclusively. He could, if he wished, secure medical attention of his own selection but at his own expense.

The beneficial result of these early provisions was that the physicians furnished by the insurer were able to decide the true medical status of the case, because as a practical problem the insurer employed physicians who stood out prominently as surgeons or diagnosticians along industrial medical lines.

The defective feature of this early provision was its failure to accomplish the employee's restoration to industry because of the legal limitations precluding adequate medical treatment. This was an injustice not only to the injured workman but to the physician treating him. These inadequate provisions defeated the salvaging of the employee.

As a second step toward industry's bearing the burden of industrial injuries, provision was made by the legislature to enable the employee to select his own physician. The reasonable cost of the services had to be paid for by the insurer, and these provisions extended the time and scope of the treatment. Where the treatment was ren-

*Presented at the fall meeting of the Massachusetts Medico-Legal Society, October 6, 1937.

Chairman, Massachusetts Industrial Accident Board.

dered by a physician selected by the employee the basis of the dispute was, in general, first, the necessity for the treatment, secondly, the adequacy thereof, and thirdly, the reasonableness of the fee or charge. When the treatment was rendered by a physician furnished by the insurer a dispute seldom arose.

As a third step toward correcting these defective provisions an amendment was passed by the legislature providing that in unusual cases the insurer should furnish adequate and reasonable medical and hospital services. Still the Industrial Accident Board was restricted in its endeavor to accomplish the fundamental purposes of the act. The Supreme Judicial Court, in an opinion rendered by Mr. Justice Carroll, the first chairman of our board, said in the Moore Case (255 Mass. 533, 535): "The statute has reference to injuries which develop unexpected or unusual complications requiring the services of experts or unusual treatment." He added: "The injuries may be unusual in the sense that they do not occur under ordinary circumstances, or that recovery is prolonged. But such facts do not make them unusual cases as the words are used in the statute."

Therefore another amendment was added by the legislature in 1927 to the effect that in cases requiring specialized or surgical treatment for a longer period, in the discretion of the board, the insurer should furnish adequate and reasonable medical and hospital services.

Following this last amendment a meeting was held with our medical adviser, the late Dr. Francis D. Donoghue, and with representatives from the medical profession, the interpretation of the terms "specialized treatment" and "surgical treatment" was agreed upon and accepted by the members of the Industrial Accident Board. "Specialized treatment" was understood to cover cases similar to those requiring sanatorium treatment, namely, treatment of blood diseases such as leukemia, skin conditions, acute, chronic or malignant, neurosyphilis incident to other treatment, and diabetic conditions complicating injuries. It was agreed that such specialized treatment when needed might be given not only by recognized specialists but by qualified general practitioners. "Surgical treatment" should be given in all cases where hospitalization was required or where the period of disability might be shortened or the result of the injury minimized. Such treatment is not necessarily operative. There are many surgical conditions that may be treated by manipulation or by mechanical or therapeutic means. The treatment of lymphangitis, operative cases of contractions, the correction of joint or soft-tissue adhesions, treatment of the results of nerve injuries, genitourinary

treatment, and various forms of heat or ray therapy may well be considered as within the scope of specialized and surgical treatment.

Few cases could fail to fall within this amended section, so that the only remaining question is that of adequacy and reasonableness as the main issues upon which we must make a decision.

Our procedure, in case medical services are not paid for by the insurer and there is no question of liability, is to refer the matter to our medical adviser, who is really a liaison officer between the medical profession and the administrative body. His position is analogous to the old family physician in whom was merged those fundamentals upon which the elaborate specialisms of our day have been built. The medical adviser gives an informal opinion upon the fact, as to the reasonableness of the charges and the necessity of the treatment. If the parties are unwilling to abide by an informal opinion either party may ask for a hearing. After the evidence is taken under oath by a single member a finding is made by the Board.

On superficial examination it would seem advisable to have a fee table. Medical bills for services rendered in industrial accident cases could be handled en masse and a very undesirable angle of the work would thus be eliminated. On the other hand, every case must be reduced to an individual problem. Were it possible to segregate injuries into groups, have a fee table for the physicians and apply a cold scientific treatment to all cases, we should not have a humanitarian law but should be reducing the workman to a robot and the profession to a trade. Some of our medical problems grow out of the type of physician handling the case. Certain doctors look at cases only from the surgical side and do not deal successfully with the patient when the surgical end result has been reached. At this time the patient needs help and encouragement to appreciate that complete recovery is always a gradual process, and that he may experience discomfort which is neither damaging nor incapacitating and requires no medical treatment.

The patient is quick to sense a spirit of intolerance toward him, he suffers discomfort, and naturally seeks a physician who will give him treatment and sympathy. The employee is ignorant of the facts that he needs no treatment and that if he receives it he is being overtreated, incidentally, there is a temptation on the part of some physicians to extend the period of treatment. Even though a surgical end result has been reached and the treatment does nothing but relieve the patient's mind and give him the satisfaction of having something further done for him, is it fur

to rule that such treatment is not necessary and thereby arouse resentment in the mind of the employee?

In determining the necessity and reasonableness of the bill for the services rendered the case must be considered in the light of the facts, which include the mental attitude of the injured man and the experience and qualifications of the physicians who have had contact with the case, as well as the genuineness of the treatment. These are all given a fair evaluation.

Other medical problems present themselves. Take for example a case of hernia. A worker has a pain in his side. This pain brings him to a physician, and when the latter inquires as to the cause, the patient immediately remembers what he was doing when he had the pain. The physician examines him, learns that this was the first pain he has ever had, and advises him that he has a hernia and needs an operation. Assuming this diagnosis to be correct, the legal question arises whether the hernia was caused or aggravated by the incident which happened when the pain first occurred. While traumatic hernias in the true sense of the term are rare, compensable hernias caused by aggravating a pre-existing condition of the groin are exceedingly common. The employee wants the operation but has no money. He has lost no time from his work but has incurred some medical expenses. If the physician really believes that there was a fundamental defect, that this has been changed into one which gives symptoms, and that the incident which the employee describes was sufficient to change the quiescent condition into an active one, he should not hesitate to perform the operation. Controversy will probably develop, and the evidence will be presented to the Board. It is the physician's duty in such a case to appear and testify, and if there has been no impartial examination prior to seven days before the hearing he is entitled to a fee for such an appearance and should request it from the presiding member. If in his opinion the facts suggest not a possibility but a probability, he is unfair to his profession and to society if he fails to co-operate in seeing that industry is charged with this economic loss. On the other hand, if he believes that the facts suggest a mere possibility, he is equally unfair if he does not openly state his opinion and prevent the burden from being placed on industry.

The physician's relation to industry is becoming increasingly important. It is evident that there is a growing need for medicolegal teaching. Our economic structures are becoming more and more

complex. Many industries, in addition to insurance companies, now maintain clinics.

A decision written and handed down by that able jurist, Mr. Justice Lummus of our Supreme Judicial Court, on September 20, 1937, in the case of *McMurdo v. Getter* and another (New Eng. J. Med. 218 402-404, 1938) is of such vital interest to the medical profession that it deserves attention. Just how far this decision may affect the contractual relation between insurers and salaried physicians is uncertain. "The position of the physician merely is not that of a servant of anyone," said the Supreme Judicial Court when the late Oliver Wendell Holmes was chief justice and Knowlton, Morton, Lathrop and Barker were associate justices. The plaintiff had sued a corporation because his disability was alleged to be due to the physician's examination. The corporation had engaged the physician to make the examination for its benefit and information. Mr. Justice Holmes held that the physician "was not an agent or servant of the corporation in making the examination, he was an independent contractor. There is no more distinct calling than that of the doctor, and none in which the employee is more distinctly free from the control or direction of his employer." This case showed that in the eyes of the law a doctor cannot place himself in a position where he is a servant of his employer. The relation of the physician to industry should and must at all times be that of an independent contractor and not that of a servant. "A person cannot do indirectly what he cannot do directly."

It is the duty of the physician to bring the fruits of medical progress to society, and thus to contribute to the welfare of the individual workers and of society as a whole. This field of service is wider than ever before, since new industries are being created and new products manufactured and utilized. The task of the medical specialist is to follow all these developments so as to give warning of the new risks to which workers are exposed, and to indicate the best methods of protection against them. This is a tremendous task. It is the individual en masse who performs work and who likewise suffers trauma. Broken personalities resist restorative measures, and a large number of our disabilities result from them. It is the physician's responsibility to provide adequate measures to restore the diminished productive power. But whatever happens, whatever the future holds for the employee, the medical profession and industry, and even the government, must always remember that the relation of the physician to the employer is that of an independent contractor and not that of a servant.

THREE TYPES OF MECKEL'S DIVERTICULUM

THOMAS F. CORRIGEN, M.D.*

NORTHAMPTON, MASSACHUSETTS

DUE recognition has been given to the fact that the anomaly described by Johann Friedrich Meckel in 1812 and known as Meckel's diverticulum does not always undergo retrogression but abides in varying degrees of persistence and patency. While diverticula are comparatively rare (the literature usually gives an incidence of 1 to 3 per cent at postmortem examination), and rarer in adults than in children, they occur, as Green¹ has shown, with sufficient frequency to warrant careful consideration and to justify detailed reports on individual cases.

Attempts have been made by different authors to classify the various types of diseases of Meckel's diverticulum according to the underlying lesion with the attending syndrome. Greenwald and Steiner² analyzed 51 cases occurring in children under fifteen and divided them into three groups: ulceration with or without perforation, diverticulitis and intestinal obstruction. Greenblatt, Pund and Chaney³ reported 18 cases with an average age of twenty-seven. These fell into six groups: peptic, with or without ulceration, obstructive, diverticulitis, umbilical, tumor and incidental. The following classification was suggested by Chesterman⁴: inflammation with or without ulceration, obstruction, fistula, neoplasms, and associated local abnormalities, such as a mesenteric cyst or enterocystoma.

The three cases reported below, observed within three years, represent characteristic types of Meckel's diverticulum: the bleeding and non-acute, the gangrenous and obstructive and the silent. Discovery of the third type is necessarily incidental. An interesting variation in the first two cases appears in the fact that in one the base of the diverticulum could be left to avert narrowing of the lumen of the bowel, whereas with the obstructive and gangrenous type resection was necessary. In both these cases the previous history showed no indication of the condition, the illness was insidious and its onset sudden, and the response to surgical treatment was prompt and complete.

All three cases were operated on at the Cooley Dickinson Hospital.

Case 1. Bleeding Meckel's Diverticulum (non-acute type). F. K., male, aged 15.

The patient had begun to look pale about 2 weeks before he was examined, and shortly afterward began to suffer intermittent pains in the lower abdomen. Four days be-

fore examination he had diarrhea, passing dark, bloody stools, the bowels continued to be loose, and he vomited several times, once after taking a cathartic and once after eating dinner. For several days he had eaten little, and felt weak, drowsy and cold. The previous history was negative, with the bowels usually regular.

Although he was fairly well developed and well nourished, the patient's color was sallow, the mucous membranes of the lips were markedly pale, and the pulse was rapid and very thready. Except for the abdomen, the physical examination was negative. In the region of the terminal ileum and cecum, the right lower quadrant of the abdomen felt doughy, suggesting a mass. The condition was diagnosed as acute ulcerative ileocolitis or a bleeding Meckel's diverticulum.

The hemoglobin was 38 per cent, there were 1,900,000 red cells and 7050 white cells. The blood was Type O (Landsteiner), the coagulation time was 5 minutes. The urine was normal.

During the first 2 days at the hospital the pulse became stronger and the general condition improved, although there were no bowel movements. There was no pain, but the mass in the right lower quadrant was still present. On the 3rd day a blood transfusion with sodium citrate was attempted. After about 60 cc. of the solution had run into the vein the patient complained of severe pain in the lower abdomen, then became cold, clammy and practically pulseless, and fainted. The transfusion was immediately stopped. The bed was put on blocks, and the patient was given salt solution into the thighs, and morphine. Shortly afterward he had a profuse, bloody bowel movement. The coagulation time was 5½ minutes. He was kept on blocks for the night, and the following day another transfusion was decided upon.

The patient was made ready for a laparotomy, which was performed simultaneously with this second transfusion. Under local anesthesia, a midline incision was made, extending from the symphysis to the umbilicus. On inspection of the small bowel, the patient complained of pain and was given a little gas-oxygen. Examination of the terminal end of the ileum and the cecum disclosed no ulcerative or inflammatory conditions. On examination of the ileum, however, a Meckel's diverticulum was brought into view, situated about 45 cm. from the cecum and lying in the left pelvis. After removal, the diverticulum was found to be completely filled with old blood. The ileum was then sutured. There was no need for resection of the bowel, as a sufficient amount of the base of the Meckel's diverticulum was left so that there was no narrowing of the lumen. During this time, the patient had been given 400 cc. of blood and was later given salt solution by vein.

On the day following the operation, the patient's red cell count was 2,530,000 and the hemoglobin 38 per cent. At no time following the operation was there any blood in the stools. On the 17th postoperative day the red-cell count was 3,879,999 and the hemoglobin 45 per cent. He was discharged on the 27th postoperative day. His general condition when he was last seen was very satisfactory.

Pathologic Report (Dr. F. D. Jones). The diverticulum was 5 cm. in length and 1.5 cm. in diameter at the base,

*Surgeon at Cooley Dickinson Hospital.

there was a constriction 2 cm below the base. The mucosa was yellowish gray in color. Rugae were prominent, except for the narrow band at the constricted portion, where there seemed to be some atrophy. The mucosa consisted of columnar epithelium of the cylindrical type and goblet cells. The other layers were the muscular mucosa, circular and longitudinal muscle fibers and serosa. The blood vessels contained many erythrocytes, and moderate perivascular lymphocytic infiltration was noted. An occasional eosinophil was found in the submucosa.

Case 2 Gangrenous Meckel's Diverticulum and Compression Obstruction of the Ileum R. A., male, aged 19

The patient awoke at 3 a. m. with a violent pain generalized over the entire abdomen. He became nauseated and vomited greenish yellow fluid, the vomiting recurring several times during the day. He continued to suffer pain, which became localized after a few hours in the lower right quadrant, extending from the midline to the flank, the maximum intensity being about 5 cm. below and medial to McBurney's point. By the time of his arrival at the hospital later in the morning, the pain had again become general and was very severe. Examination revealed some distention of the upper portion of the abdomen, with no spasm or rigidity under pressure. In the lower abdomen, palpation over the right side elicited some tenderness, but there was no marked muscle spasm. The chief complaint seemed to be centered about the umbilicus. A diagnosis of probable acute appendicitis was made, with another physician disagreeing.

The previous history included chorea at the age of 6 or 7, and measles, scarlet fever, mumps and whooping cough in childhood. Two or three months before admission he had awakened from a sound sleep suffering a sharp general pain in the abdomen. This had lasted only a moment or two and had not recurred until the present. He had been very active and healthy and had not had any digestive disturbances. In the physical examination the eyes, ears, nose and throat were negative, the chest was normal, and there were no heart murmurs.

When the abdomen was opened by a right rectus incision, free blood was found. The appendix appeared normal. When the right hand was placed in the pelvis a great deal of free blood welled up. With the enlargement of the incision toward the midline, several loops of the small bowel were found to be absolutely flat. In following up the ileum, a large mass was disclosed. This was a strip of gangrenous material approximating 4 cm at the base and coming off from the cecum, which had curved over and had completely encircled one loop of gut. The proximal portion of this loop was markedly distended and reddened. The gangrenous area had extended through the mesentery of the loop and through the mesentery of the original loop of ileum to which it was attached, so that it completely encircled both the loop of the small bowel and the loop of ileum which was its original attachment. The Meckel's diverticulum was about 17 cm long. The distal portion of the diverticulum was freed and drawn through the two openings in the mesentery. With the loosening of the distal portion, the bowel immediately assumed its normal condition. A resection of the gut was then done, in order to remove the gangrenous portion of the bowel along with the diverticulum. The postoperative course of the patient was uneventful, and within 13 days he had made a very satisfactory convalescence.

Case 3 Silent Meckel's Diverticulum and Gangrenous Ovarian Cyst M. G., female, aged 43

One week after a normal menstrual period, the patient suffered a sudden, sharp, severe pain in the lower left pel-

vis. For 5 days she continued to suffer pain, from which repeated enemas brought no relief. On the 5th day she consulted a physician and was sent to the hospital. Seven months before, there had been a gradual increase in the size of the lower abdomen, particularly on the left, but until the present illness she had suffered no discomfort.

Except for the abdomen and for slight rapidity of inspiration and expiration, physical examination was negative. The abdomen was markedly distended. The outline of a mass could be seen over the left lower quadrant, extending from about the midline over the entire left pelvis and up to about the level of the umbilicus. Rectal examination gave the impression of a definite, rounded, smooth mass about the size of a large grapefruit. This mass was extremely tender to the touch, and during the examination the patient complained of considerable pain.

The red cells numbered 4,560,000 and the white cells 21,000, with 90 per cent polymorphonuclears.

A midline incision was made from the symphysis to the umbilicus. Upon opening the abdomen, some dark red blood was found free in the peritoneal cavity. As preparation was being made for walling away the large, black and gangrenous cyst of the ovary, which had been readily found, a definite Meckel's diverticulum came up into the wound. The diverticulum was about 45 cm from the cecum, and its walls were much thinner than the walls of the ileum. It contained no fecal matter but was distended with gas, as was practically all the small bowel. The cyst and diverticulum were removed without difficulty. The patient had an uneventful convalescence.

Pathologic Report (Dr F. D. Jones) The diverticulum measured 4 cm in length and 1.8 cm. in diameter. The serous surface was pink. The wall was 4 mm. in thickness, and the well-differentiated mucosa was gray, glistening and velvety. The diverticulum was pear shaped, with the largest diameter at the base. The mucosa was made up of glands in which numerous goblet cells were found. These glands were closely packed in a delicate stroma. The normal muscular coat of the intestine was present.

The symptomatology of a diseased Meckel's diverticulum depends on the pathologic changes that have taken place. In order of frequency, the symptoms associated with hemorrhage from the rectum, according to Chesterman,⁴ are anemia, pain, vomiting and bowel irregularity. The blood is usually dark, unmixed with mucus or pus. Greenwald and Steiner² noted in the peptic type without perforation, hemorrhage, abdominal pain, nausea and vomiting and weakness. There may be no abdominal signs, or there may be tenderness, either on the right or left, and in some cases a palpable mass. Radiological examination is usually negative. Secondary anemia may be severe.

Diagnosis is usually made by a process of exclusion. Between the ages of five and fifteen, melena is unusual and should suggest the possibility of a Meckel's diverticulum.

The above symptom-complex is illustrated in Case 1. Pathological examination, however, revealed no evidence of ulceration. Chesterman⁴ has discussed the etiology of hemorrhage and states that very few cases have been recorded of un-

doubted hemorrhage from diverticula which showed no signs of either aberrant mucosa or ulceration. He believes that recurrent inflammation of a hemorrhagic nature may be the cause.

Obstruction, either of the bowel or of the diverticulum itself, may be caused by bands or adhesions, by intussusception or volvulus, by coils of the ileum wrapped around the diverticulum or, as in Case 2, by the diverticulum being coiled around the intestine.

In the series described by Greenwald and Steiner,² obstruction occurred in 15 of the 51 cases. In 9 the obstruction was due to the presence of bands, in 5 to intussusception, and in 1 the ileum had become wrapped around the diverticulum. Seven of the 18 cases reported by Greenblatt, Pund and Chaney³ developed partial to complete intestinal obstruction, 2 of these were due to intussusception and 1 to volvulus. In cases of this type the onset is usually acute, with abdominal pain, nausea and vomiting. Infrequently there is a history of intestinal bleeding.

The gangrenous condition of the diverticulum, with free blood in the abdomen, as found in Case 2, suggests that here we may have a combination of diverticulitis with perforation and intestinal obstruction.

In the majority of instances, however, Meckel's diverticula give no symptoms but are discovered by chance during abdominal operations or at autopsy. Case 3 represents this passive or incidental type.

Treatment is invariably surgical. When hemorrhage has occurred, transfusions should be given to combat anemia. When found in the course of an operation a "silent" diverticulum should be removed, as pathologic changes may develop.

SUMMARY

Several classifications of the types of diseases of Meckel's diverticulum as reported in the literature are presented.

Cases illustrating three important types—the hemorrhagic, the obstructive and the silent—are presented, and the operative procedures described. Symptoms and diagnosis are discussed.

SULFANILAMIDE IN THE TREATMENT OF GONORRHEA IN THE FEMALE

BURTON C GRODBERG, MD,* AND EDMUND L CAREY, MD†

BOSTON

IN the out-patient department of the Boston City Hospital we have an excellent opportunity to study gonorrhea in the female. All the cases included in this study have been treated with sulfanilamide. Harvey and Janeway, Young, Helmholz and Osterberg have pointed out that, in doses of 80 gr daily, it is a dangerous agent. Being faced with its unknown toxicity, we decided from the outset to utilize smaller doses over a longer period. We have prescribed an average daily dose of from 20 to 30 gr for a four- to six-week period. No intramuscular injections have been given. The drugs used have been Prontylin and Stramid, both products of reputable houses.

In every case we have demonstrated the gonococcus intracellularly in smears of the exudate

stained by Gram's method. The smears have been taken from the urethra, the cervix or the region of Bartholin's glands, both for diagnosis and as a criterion for cure. We have not utilized cultures, nor have we routinely included the complement-fixation test.

Each patient, after the diagnosis had been established, was informed of her disease and given definite instructions. The drug was furnished by the Massachusetts Department of Public Health and at each visit dispensed through our Social Service Department. This treatment was the only one utilized, and the patients were told not to take medicated douches except in special cases. Originally these patients were seen three times a week, but later this was changed to weekly visits. They were advised to refrain from coitus and the use of alcohol. The usual public-health measures to prevent extragenital spread were carried out. In this series we have excluded cases of the chronic type and acute cases which did not have a positive

Read before a meeting of the New England Obstetrical and Gynecological Society at the Boston City Hospital December 1 1937.

smear, but the latter have been treated with results similar to those reported in this study

The type cases have been acute endocervicitis, acute urethritis, vulvovaginitis, both adult and juvenile types, and acute pelvic inflammatory disease. We have treated a few patients in various stages of pregnancy. Our experience has been the same as that of Kenny, Johnston, von Haebler and Miles, who found no exaggeration of pre-eclamptic symptoms in their cases of pyelitis of pregnancy following treatment with sulfanilamide.

The characteristic course of our patients has very closely simulated that of Cook and Buchtel, Helmholz and Osterberg, Reuter and Orr, who used the larger doses, the only difference being a slightly slower response in our cases. We found

(1) In less than one week, usually about three to four days, there was subjective improvement. Patients reported diminishing discharge and those who had had pain stated that it decreased and soon ceased.

(2) The smears taken at about one week after the onset of medication showed fewer gonococci, with the organisms situated extracellularly.

The drug was also ineffective in the majority of cases of infantile vulvovaginitis, utilizing both topical and oral sulfanilamide medication, this was true in spite of doses approximating by weight those of other observers. Long and Bliss contend that sulfanilamide is most efficacious in an alkaline medium. Our failure with topical application may be attributed to the fact that the vagina is notoriously acid, however, we did not supplement oral medication with alkalis in our successful adult cases. In the future we may follow another series topically and orally, with the additional administration of alkalis.

The juvenile patients in whom there was no response to sulfanilamide showed excellent results with daily Amniotin suppositories of 2000 rat units, with a total dosage of 24,000 to 36,000 units.

Contrary to the experience of Archer and Discombe, Cook and Buchtel, Helmholz and Osterberg, and Brunsting, we have had a minimum of toxic manifestations. In no case were we forced to discontinue the drug because of their appearance. There were 4 adults who complained of giddiness and nausea, but no case of cyanosis. In the children, when the dosage was raised, we

Table 1 Summary of Results, Dosage and Duration of Treatment

DIAGNOSIS	No OF CASES		AVERAGE DAILY DOSE Sulfanilamide	AVERAGE DURATION OF TREATMENT	AVERAGE FOLLOW UP PERIOD	AVERAGE No OF NEGATIVE SMEARS IN CURED CASES
	TOTAL	CURED				
Acute pelvic inflammatory disease	15	13 (87%)	8T	7MO	7MO	4
Acute endocervicitis	8	7 (88%)	28	1½	2½	5
Acute urethritis and endocervicitis	3	2 (67%)	24	1½	3	4
Bartholinitis	1	1 (100%)	27	1½	2	6
Vulvovaginitis (infantile)	5	1 (20%)	20	1½	2	3
			8	2½	3½	2
Totals (excluding infantile cases)	21	23 (85%)				
Averages (excluding infantile cases)			26	1½	2½	4

(3) The purulent nature of the smear continued, but in from seven to ten days gonococci were absent.

(4) The discharge shortly thereafter became mucoid, and no pus cells were seen on examination.

(5) Acute masses, both tubo-ovarian and vulvovaginal, resolved in about ten to fourteen days. (One of our pregnant cases had a Bartholin gland in which infection was definitely increasing, in three or four days following the onset of medication this became painless, and in less than two weeks was no longer palpable.)

(6) The cervix lost its acute inflammatory appearance and the discharge ceased. (Those cervixes which were eroded with ectropion were treated as chronic endocervicitis, at first with depletion douches and glycerin tampons and later with cauterization to control the local lesion.)

We used topical applications of Prontosil in a few of our early cases, with no improvement

observed two skin rashes similar to those described by Brunsting and by Schwentker and Gelman. These were vesicopapular, itchy and limited largely to the hands, face and legs—all exposed surfaces.

Our criteria for cure were as follows:

(1) At least three negative smears, both from cervix and urethra, at weekly intervals (at least one was either pre- or post-menstrual).

(2) Absence of any symptomatology or clinical signs, such as discharge, pain, injection, inflammatory masses, or pain on movement of the cervix and uterus.

In all, we have included in this preliminary series 32 cases. We have double this number which we have excluded either for failure to conform to our criteria or to continue treatment. The former group has shown as good a clinical response as those we are discussing.

There were 85 per cent cures in our adult group (Table 1). These figures compare well

with the 87.5 per cent reported by Orr, the 80 per cent reported by Brown and Bannick and the similar percentage of Dees and Colston. Many of the cases reported by these authors, however, occurred in men, and all observers report a lower percentage of cures in women. In the juvenile type of vulvovaginitis only 1 case (20 per cent) was successfully treated with sulfanilamide. This compares favorably with the results of Hageman and Blake, who report 1 cure in 3 patients.

As yet we have had no relapses and it is too early to consider recurrences.

SUMMARY

A series of 32 cases of gonorrhea in women has been treated with relatively small doses of sulfanilamide. Although the percentage of cures may be slightly less than that reported following the use of larger doses, this fact is compensated for by the absence of toxic manifestations.

We are indebted to Miss Mary Parker and Miss Gladys Madoff of the Social Service Department, and Miss Marion Johnson, our technician, for their co-operation in this study.

THE MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Annual Meeting, June 1, 1938

THE annual meeting of the Council of the Massachusetts Medical Society was called to order by the president, Channing Frothingham, Suffolk, in the Penthouse of the Hotel Bradford, Boston, on Wednesday morning, June 1, at 10.30 o'clock. There were 234 councilors present, the list will be found in Appendix No 1.

The Secretary presented the minutes of the last meeting (February 2, 1938) as published in the *New England Journal of Medicine*, issue of March 17, 1938. After the usual query concerning corrections or additions, the President declared the records approved as published.

The following obituaries of the four councilors who had died since the last meeting were read by the President.

Dr John S Leard, of West Roxbury, died at his home, February 3, after a week's illness. He was in his seventy second year.

A native of Prince Edward Island, he graduated from Prince of Wales College and received his degree from the University of Pennsylvania School of Medicine in 1894.

Dr Leard was a member of the original staff of the Faulkner Hospital and was organizer and first president of the West Roxbury-Roslindale-Jamaica Plain Medical Association. He was a fellow of the American Medical Association. At the time of his death he was vice president of the Jamaica Plain Dispensary and a member of the Clinical Club of Boston and of the Norfolk District Medical Society, of which he was a past president, councilor and censor.

His widow, a daughter and twin sons survive him.

Dr Arthur R. Crandell died at his home in Taunton, March 19. He was in his sixty ninth year.

A native of Taunton, he attended the high school there, later graduated from Harvard University and received his degree from the Harvard Medical School in 1896. Since 1900 he had been consulting physician at the Morton Hospital in Taunton. He was a fellow of the American Medical Association. His memberships included the New England Pediatric Society and the Taunton Doctors Club. Dr Crandell was a councilor and supervising censor of the Massachusetts Medical Society for many years.

His widow, a daughter, a sister and three grandchildren survive him.

Dr William D Walker, of Andover, died April 12. He was in his sixty first year.

A native of St. John, New Brunswick, he was the son of Dr Thomas Walker, physician-surgeon and colonel of the 62d regiment of Canadian militia. He received his degree from Tufts College Medical School in 1905. He served as school physician at Andover for many years and was on the school committee for six years.

Dr Walker was a fellow of the American Medical Association and a member of the Lawrence Medical Club.

At the time of his death he was president of the Essex North District Medical Society.

Dr Francis M McMurray, of Fitchburg, died at his home May 8. He was in his sixty sixth year.

Born in Merrimack, he attended the Fitchburg High School, graduated from Brown University and received his degree from the New York University College of Medicine in 1899.

Dr McMurray was president of the staff at the Burbank Hospital for many years and had been chief anesthetist at the hospital for several years. He was a fellow of the American Medical Association and was a past president of the Worcester North District Medical Society and its secretary at the time of his death.

His widow, a daughter and a brother survive him.

The councilors stood in silent tribute.

After the roll call of the nominating councilors, the following-named gentlemen retired to consider the nomination of officers and orator for the ensuing year.

W D A Kinney, *Barnstable*, H J Downey, *Berkshire*, W H Allen, *Bristol North*, E F Cody, *Bristol South*, F W Snow, *Essex North*, J F Jordan (alternate), *Essex South*, W J Pelleter (alternate), *Franklin*, G L Schadt, *Hampden*, L N Durgin, *Hampshire*, R R Stratton, *Middlesex East*, F D Lambert, *Middlesex North*, A W Dudley, *Middlesex South*, W A Griffin, *Norfolk*, C A Sullivan, *Norfolk South*, W H Pulsifer, *Plymouth*, E P Joslin (special alternate), *Suffolk*, R P Watkins, *Worcester*, and E A Adams (alternate), *Worcester North*.

There being no alternate from Suffolk to cover the absence of Dr Lahey, the chair obtained permission of the Council to appoint Dr Elliott P Joslin as alternate from Suffolk.

REPORTS OF STANDING COMMITTEES

Membership and Finance

The chairman, Dr David N Blakely, Norfolk, presented the report of his committee which recommended that seven fellows be allowed to retire, that the dues of two fellows be remitted, that ten fellows be allowed to resign and that nine fellows be allowed to change membership from one district society to another without change of legal residence. The report was accepted and the recommendations approved. (See Appendix No 2.)

The financial part of the report by Dr Blakely recommended that the surety bond of the Treasurer in the amount of \$15,000 be renewed for one

year from June 19, 1938. This report was likewise accepted and the recommendation approved.

Although not properly a part of the report of the Committee on Membership and Finance, action on the restoration of fellows and the appointments of committees to consider applications for restoration were included at this point.

The Council approved of the recommendations of committees previously appointed to consider petitions for restoration to the privileges of fellowship of nine applicants. (See Appendix No 3.)

The Council approved of the committees nominated by the President to consider petitions for restoration to fellowship which had been received from eleven fellows previously deprived. (See Appendix No 4.)

Ethics and Discipline

This report, which was presented by the chairman, Dr. David Cheever, Suffolk, and which contained no recommendations, was accepted by the Council. (See Appendix No 5.)

At the close of his report Dr. Cheever announced his resignation from the committee. The Council expressed its appreciation of the long and faithful service rendered by him on this committee by a spontaneous outburst of applause.

Medical Education and Medical Diplomas

In the absence of the chairman, Dr. Fitz, the report was read by Dr. Charles A. Sparrow, Worcester. (See Appendix No 6.) There being no recommendations in the report, it was duly accepted by the Council.

State and National Legislation

The chairman, Dr. Charles C. Lund, Suffolk, presented an informal report in which he reviewed the work of the committee for the past year. He pointed out that, while one hundred per cent success had not attended the committee's efforts, most of the major issues had been acceptably handled. The Legislature did, however, extend until 1941 the provisions of the law previously enacted which sets up an approving authority to scrutinize all medical schools graduating individuals who subsequently apply for licensure. He reported that the osteopathic and chiropractic bills, together with bills designed to improve the dispensing of drugs and poisons, were placed in the hands of a recess commission of the Legislature. The committee does not know the final form which the legislation will take. He commented upon the work of the committee in carrying out the instructions given by the Council at its meeting on February 2, 1938, which were designed to support Dr. Henry D. Chadwick for reappointment as commissioner of public health. He reported that, while one nomination had been made by the Governor, it had not been

confirmed by the Governor's Council and that no subsequent nomination had yet been made.

He stated that the committee was doing all in its power to persuade the Legislature to pass a reasonable bill looking toward the reorganization of the Department of Mental Diseases. It is the hope of the committee that action by the Legislature may be postponed until the next annual session in order to permit further study during the summer and fall.

In the opinion of the committee there were certain parts of the bill to regulate the practice of nursing which were admirable but, as the bill had been hurriedly drawn, it needs further study, and the committee seeks to have this study conducted by a recess commission during the coming summer.

Under the heading of national legislation, the chairman referred to a bill (H. R. 4650) which had passed the House and Senate and which extends medical privileges to osteopathic physicians. He stated that the *Journal of the American Medical Association* had recently published an editorial on the matter and, from the information received, it appears that the Senate had passed the bill as a result of deliberate misrepresentation by the proponents which implied that the provisions of the bill had met with the approval of organized medicine. The committee recommended that the Council pass a resolution to be sent by telegraph to President Roosevelt requesting that the bill be vetoed.

The chairman expressed the opinion that certain of the legislators believe that the Massachusetts Medical Society is ultraconservative and does not co-operate in efforts made to abolish various abuses. In his opinion the Society should do what it can to facilitate the work of various state departments by supporting proper legislation.

Dr. Lund paid his respects to Dr. Arthur W. Marsh, Worcester, who had submitted his resignation from the committee after a long period of faithful and effective service. He commented upon the organization perfected by Dr. Marsh in his district and submitted it as an inspiration to the other district societies. The committee also extended its thanks and appreciation to the members of the district legislative committees for the service that they had rendered during the past year. The report of the committee was duly accepted. The specific recommendation was that the following telegram be sent to President Roosevelt over the signature of the president of the Massachusetts Medical Society:

At its annual meeting, the Council of the Massachusetts Medical Society voted unanimously to urge you to veto H. R. 4650. This bill would give osteopaths standing that they do not now have and would be, in our considered opinion, detrimental to the best interests of the public.

The recommendation was duly approved.

Public Health

The report by the chairman, Dr Robert B Osgood, Suffolk, was duly accepted (See Appendix No 7) The joint resolution presented in the report had been referred to the Section of Obstetrics and Gynecology and the Council was informed that the Section had taken favorable action

Medical Defense

The report of the committee by the chairman, Dr Franklin G Balch, Suffolk, was duly accepted (See Appendix No 8)

REPORTS OF SPECIAL COMMITTEES

Postgraduate Instruction

The report by the chairman, Dr Frank R Ober, Suffolk, was duly accepted (See Appendix No 9) The committee's recommendation that the Society continue to co-operate with government agencies in giving extension postgraduate instruction was duly approved by the Council The recommendation that the Massachusetts Medical Society sponsor a Clinical Congress was discussed in some detail and was finally approved and the committee instructed to work out the details

Public Relations

The report was presented by the secretary, Dr Elmer S Bagnall, Essex North (See Appendix No 10) Dr Bagnall referred to what has come to be known locally as the Lane Resolution but which is in fact a resolution presented to the House of Delegates of the American Medical Association by the delegates from Ohio at the annual meeting in 1937 It was stated that this resolution has been adopted by eighteen states After some discussion, in which it was pointed out that the acceptance of the report did not carry with it approval of the recommendations contained therein, the report was finally accepted by the Council

Dr Lane moved to substitute the original resolution submitted by him for Recommendation No 1 made by the committee. The resolution follows

RESOLVED, That we approve the prepared hospital plan with the stipulation that the contract benefit provided by group hospitalization insurance shall be limited to hospital accommodations such as room, bed, board, operating room facilities and general nursing care ordinarily provided by hospitals, routine drugs, and the routine services of interns only when acting under the direction of the attending physician, and that except as stated above, the contract shall not include the services of physicians either general or special.

There was discussion by Dr Walter A Lane, Norfolk, Dr Albert A. Hornor, Suffolk, Dr Frank H Lahey, Suffolk, Dr Michael A Tighe, Middlesex North, Dr Leroy E Parkins, Suffolk, and Dr Charles J Kickham, Norfolk The Presi-

dent then called for a vote and announced that Dr Lane's motion was lost.

Recommendation No 1 in the report was next presented The recommendation was adopted without opposition

The second recommendation was then presented and was finally adopted in the following modified form

WHEREAS, This report leaves unsolved the important question of what constitutes desirable service by a hospital, be it

RESOLVED, That the Council refer this question to the Committee on Public Relations for study and for report at the next annual meeting of the Council, and that the Council further recommends that the organized anesthetists, roentgenologists and pathologists take up with the Hospital Council of Boston and the New England Hospital Association certain very important and fundamental problems in medicine related to this discussion with the hope of reaching a decision which will be mutually agreeable to hospitals and organized medicine.

The third recommendation was then presented and was finally divided into two parts first, "that the Council approve the survey the American Medical Association is making on the adequacy of medical care" After considerable discussion, in which Dr Michael A Tighe, Middlesex North, Dr Frank H Lahey, Suffolk, and Dr John P Monks, Suffolk, took part, the Council voted to approve of this part of the recommendation

The second part of the third recommendation, namely "that the Massachusetts Medical Society accept responsibility for the proper analysis and tabulation of the material collected by the district societies" was referred to the Committee on Membership and Finance (This recommendation was subsequently referred to the newly appointed Committee on Financial Planning and Budget.)

Insurance Relations

From the report by the chairman, Dr William G Curtis, Norfolk South, it appears that this committee continues to function in its endeavor to promote better relations among the insurance companies, the hospitals and physicians There was a joint meeting of presidents and secretaries from certain district medical societies, together with hospital and insurance executives, held at the Chamber of Commerce building on Monday, March 21, 1938 The entire arrangement, as previously presented, was discussed in detail Apparently the majority of the participants were pleased with the progress which has been made The meeting was in charge of a committee composed of Dr William G Curtis, Dr George A MacIver, Mr James H Holland and Mr Richard J Dunn It was evident that the work of Dr Henry M Landesman, the secretary of the committee, had been most effective The report was accepted as one of progress

Physical Therapy

The report by the chairman, Dr Franklin P Lowry, Middlesex South, was accepted by the Council (See Appendix No 11)

ELECTION OF OFFICERS

The senior member of the nominating councilors presented the following list of candidates for election as officers and orator of the Massachusetts Medical Society for the ensuing year

For president Channing Frothingham, Boston.
For vice president A. Warren Stearns, Billerica.
For secretary Alexander S Begg, West Roxbury
For treasurer Charles S Butler, Boston.
For orator Elliott P Joslin, Boston.

The President asked if there were any other nominations from the floor There being none, Dr Lane, Norfolk, moved that, under suspension of the rules, the Secretary be directed to cast one ballot for the list as nominated by the nominating councilors The motion was duly seconded and, there being no discussion, the question was put and the Council voted to elect the officers and orator as nominated The President then declared that the officers and orator for the ensuing year had been duly elected

The standing committees for the ensuing year were nominated by the President as follows

COMMITTEE ON PUBLICATIONS

R. I Lee, *chairman* R. M. Smith, F. H. Lahey,
J. P. O'Hare, Conrad Wesselhoeft.

COMMITTEE OF ARRANGEMENTS

R. P. Stetson, *chairman* Augustus Thorndike, Jr.,
E. J. O'Brien, Jr., W. T. O'Halloran, J. A. Halsted

COMMITTEE ON ETHICS AND DISCIPLINE

R. L. DeNormandie, *chairman* C. J. Kickham,
R. R. Stratton, W. J. Brickley, A. G. Rice

COMMITTEE ON MEDICAL EDUCATION AND MEDICAL DIPLOMAS

Reginald Fitz, *chairman* E. S. Calderwood, A. W. Stearns, A. R. Gardner, G. D. Henderson

COMMITTEE ON STATE AND NATIONAL LEGISLATION

C. C. Lund, *chairman* B. F. Conley, A. M. Butler
C. A. Robinson, D. L. Lionberger, *secretary*

COMMITTEE ON MEMBERSHIP AND FINANCE

H. Q. Gallupe, *chairman*, G. C. Caner, J. E. Fish,
H. F. Newton, P. H. Leavitt

COMMITTEE ON PUBLIC HEALTH

R. B. Osgood, *chairman* Gerald Hoeffel, S. C. Dalrymple, H. L. Lombard, F. P. Denny

COMMITTEE ON MEDICAL DEFENSE

F. G. Balch, *chairman*, E. D. Gardner, F. B. Sweet,
A. W. Allen, W. R. Morrison

COMMITTEE ON PERMANENT HOME

W. H. Robey, *chairman* C. G. Mixter, J. M. Birnie,
C. S. Butler, E. C. Miller

In each instance Dr Frothingham called for additional nominations, and there being none, each committee was declared appointed On motion of Dr Charles E. Mongan, Middlesex South, duly seconded, the Secretary was instructed to write a letter of appreciation to those men who have retired as chairmen of standing committees and who have served the Society so long and faithfully in this important work

PRESENTATION OF CHANGES IN THE BY-LAWS

These were duly presented as shown in the report of the annual meeting of the Society It will be noted that Amendment No 1 is designed to cover the provisions included in a resolution introduced by Dr Alexander A. Levi, Middlesex South, and adopted by the Council June 2, 1937 Amendments No 2 and 3 were introduced by Dr John M. Birnie, Hampden, for the purpose of uniformity in methods of procedure Amendments No 8 and 9 were presented by the committee of recent presidents appointed by the Council at its meeting February 2, 1938 Dr Mongan, Middlesex South, presented a minority report but withdrew the report when the amendments were altered as subsequently published

INCIDENTAL BUSINESS

The action of the Board of Censors of Bristol South District in examining and admitting to fellowship the following-named individuals was confirmed by the Council. These names were received too late for inclusion in the list published in the *New England Journal of Medicine* for April 21, 1938

Filbert Avila Silveira, Jr., St. Luke's Hospital, New Bedford Boston University School of Medicine, 1937

Manuel Ferreira Sousa, St. Luke's Hospital, New Bedford McGill University Faculty of Medicine, 1937

The President announced that he was in receipt of a communication submitted by Dr Henry M. Landesman, Norfolk, recommending that some action be taken to encourage members of the profession to submit to a thorough annual physical examination under proper auspices The President announced that the communication would be referred to the Committee on Public Relations

The President read the following communication from the Hampden District Medical Society

The Hampden District Medical Society at its annual meeting on April 26, 1938, disturbed by the lack of common policy and action within the various districts of the Massachusetts Medical Society regarding graduates of unrecognized medical schools, urges that the Council at its next regular meeting take steps to remedy this situation.

Voted, that the Hampden District Medical Society convey the above to the Council of the Massachusetts Medical Society

H. L. SMITH, *Secretary*
Hampden District Medical Society

The meeting adjourned at 1.35 p m and was followed by the Cotting Luncheon

ALEXANDER S BEGG, *Secretary*

APPENDIX NO 2

REPORT OF THE COMMITTEE ON MEMBERSHIP
AND FINANCE ON MEMBERSHIP

This committee recommends

1 That the following named seven fellows be allowed to retire under the provisions of Chapter I, Section 5, of the by laws

Canedy, Frederick Snow, Wellfleet, with remission of dues, 1938

Drake, Arthur Knowlton, Toulon, Illinois, with remission of dues, 1938

Hanson, Justus Greeley, Northampton, with remission of dues, 1938

Johnson, Frederick William, Boston.

Moir, Marguerite Winifred, West Roxbury, with remission of dues, 1935, 1936, 1937, 1938

Robbins, Fred Gibson, Boston.

Woodbury, Sullman Philetus, Millers Falls, with remission of dues, 1938

2. That the dues of the following named two fellows be remitted under the provisions of Chapter I, Section 6, of the by laws

Bond, Katherine Marie Erickson, Stoncham, 1937

Staples, Clarence Hathorne, Malden, 1938

3 That the following named ten fellows be allowed to resign under the provisions of Chapter I, Section 7, of the by laws

Crittendon, George Alanson, Springfield, with remission of dues, 1936, 1937, 1938

Downing, Francis Harold, Fresno, California, with remission of dues, 1938

Gundersen, Sven Martin, Hanover, New Hampshire, with remission of dues, 1938

Hannaford, Charles William, Portsmouth, New Hampshire.

Monette, Camile Joseph, Manchester, New Hampshire, with remission of dues, 1938

Rapoport, Boris David, New York City, with remission of dues, 1938

Strong, Paul Theodore, Mount Herman, with remission of dues, 1938

Sullivan, Charles Noyes, New Britain, Connecticut, with remission of dues, 1938

Gobert, Solomon, Everett.

Weissman, Ruth, Boston, with remission of dues, 1938

The last two fellows, Drs Gobert and Weissman, submitted their resignations on request of the Committee on Ethics and Discipline under the provisions of Chapter VII, Section 4, of the by laws.

4 That the following named nine fellows be allowed to change their membership from one district society to another without change of legal residence, under the provisions of Chapter III, Section 3, of the by laws

From Essex South to Suffolk
Mason, Nathaniel Robert, Marblehead

From Hampshire to Hampden
Miller, Ralph Thompson, Ware.
Starbuck, Amber Angela, Middlefield.

From Middlesex South to Norfolk
Bearse, Carl, Newton

From Middlesex South to Suffolk
Kennard, Harrison Eisenberry, Newton

From Norfolk to Suffolk
Graves, Roger Cutler, Brookline.
Ross, Rex Lewis, Jr., Wellesley Hills
Wetherbee, Winthrop, Brookline.

From Plymouth to Suffolk
Cheney, Robert Cartwright, Duxbury

DAVID N. BLAKELY, *Chairman.*

APPENDIX NO 3

REPORTS OF COMMITTEES APPOINTED TO CONSIDER
RESTORATION TO FELLOWSHIP

Restoration to fellowship was recommended for the following nine former members

J. B. Bakst, Lynn (Committee Frank E. Stone, John W. Trask and Saul M. Marcus)

Frederick W. Celce, Holyoke (Committee Edward P. Bagg, Jr., Fred H. Allen and Philip H. Clarke).

Abraham Green, Brookline (Committee Charles J. Kickham, Albert Ehrenfried and John A. Seth)

Aaron Kaufman, Boston (Committee Joseph J. Skirball, Allen P. Joslin and Maurice B. Strauss)

Raoul J. LeBeau, Spencer (Committee James C. Austin, John R. Fowler and Alfred W. Brown) The committee recommended remission of past dues

Joseph H. McLaughlin, Dorchester (Committee Henry F. R. Watts, Carlton E. Allard and William J. Walton)

Edward C. Messer, Dorchester (Committee David G. Eldridge, Samuel Nadel and John B. Hall) The committee recommended remission of past dues for one year (1932)

Morris J. Ritchie, Westfield (Committee Archibald J. Douglas, Edward S. Smith and Robert M. Marr)

Harry Silbert, Salem (Committee J. Frank Donaldson, Charles L. Curtus and John R. Shaughnessy)

APPENDIX NO 4

COMMITTEES APPOINTED TO CONSIDER PETITIONS
FOR RESTORATION TO FELLOWSHIP

The following committees were appointed to consider the petitions for restoration to fellowship of the following eleven former members

For Wyman Berenson, Mattapan
Samuel Nadel, Joseph I. Grover and Arthur T. Ronan

For Lillian D Chapman, Boston
 Louisa Paine Tingley, Florence L. Meredith and
 Marianna Taylor

For Oscar F Cox, Jr, Brookline
 Charles J Kickham, Maurice Gerstein and Frank
 W Marlow, Jr

For Max H Hymen, Lowell
 Mason D Bryant, Daniel J Ellison and Harold
 L. Leland.

For William Koppel, Framingham
 Hyman Morrison, Myer I. Berman and B Thur
 ber Guild

For George H. Lyons, West Roxbury
 Herbert L. Johnson, David L. Lionberger and
 Gerald L. Doherty

For Harold R. C. Mahar, Orange
 Stanton J Ten Broeck, Albert C Leach and
 Kirke L. Alexander

For J W P Murphy, Peabody
 John J Hickey, Ralph E. Foss and John F Brad
 ley

For Bernard H. Robinson, Newton Centre
 Max Ritvo, William F Cotting and Oliver G
 Tinkham.

For Samuel Kamberg, Boston
 Rudolph Jacoby, Somers Fraser and Seth M
 Fitchet.

For Francis J Vaccaro, Pittsfield
 Hugh J Downey, P J Sullivan and John J
 Boland.

APPENDIX NO 5

REPORT OF THE COMMITTEE ON ETHICS AND DISCIPLINE

During the year just ending nine meetings of the full committee were held, and at least as many conferences between two or more members. Eight personal hearings were accorded to fellows against whom complaints had been lodged.

The general character of complaints received and investigated was as follows

Unethical publicity — 16
 Unethical conduct in the practice of medicine — 5
 False or misleading testimony in court — 4
 Unethical behavior toward other physicians — 2
 Participation in the exploitation of nostrums — 2
 Collusion in fake damage suits — 1
 Aiding in advertising a commercial product — 1
 Abortion — 1
 Contract practice — 1
 Miscellaneous — 3

The disposition of the more important cases was as follows

Three fellows were recommended to the President for admonition.
 Two fellows were asked to resign from the Society and complied.
 Six fellows were rebuked orally or by letter
 Two fellows apologized in letters to the *Journal*
 No boards of trial were held.

Matters of especial interest were as follows

A fellow who, in connection with his hearing by a board of trial of a complaint against him, had brought suit for libel against the chairman and another

fellow, was recommended to the President for admonition, and was permitted to make a public apology in the pages of the *Journal*, in lieu of other proceedings against him

The cases of the two fellows whose resignations were asked for and received are naturally of great interest and importance. The first testified as an expert witness for the plaintiff in a suit for malpractice against a physician. In presenting his qualifications as an expert he made statements which proved to be false. The presiding justice declared a mistrial and fined him for contempt of court, and the Board of Registration in Medicine suspended his license for six months. The second fellow testified as an expert witness for the plaintiff in a suit against the estate of a deceased physician. The committee reviewed the official transcript of the testimony and found that the fellow had made many exaggerated and misleading statements in many of the issues involved, so that the testimony tended consistently toward the conviction of the apparently innocent defendant, and to defeat the ends of justice. This case had not been brought before the Board of Registration in Medicine, and the committee did not bring it to its attention, feeling that a resignation from the Society constituted punishment enough.

Throughout the year the committee has continued to co-operate with the Board of Registration in Medicine, especially by conferences between the chairman, and the secretary of the Board. It is believed that this co-operation can be continued and developed to mutual advantage.

During the year a beginning was made of an effort to standardize and formulate the attitude of the committee, and therefore of the Society, toward publicity pertaining to fellows in various situations, especially to the so-called education of the public in medical matters through the press and the radio. A tentative set of regulations was presented to the Council at the last meeting and it is planned to revise this if necessary and make it authentic.

DAVID CHEEVER, *Chairman*

APPENDIX NO 6

REPORT OF THE COMMITTEE ON MEDICAL EDUCATION AND MEDICAL DIPLOMAS

The Committee on Medical Education and Medical Diplomas has held two formal meetings during the year for the purpose of inspecting diplomas presented by candidates from foreign schools or from domestic schools or colleges not on the list recognized by the Society. This duty becomes increasingly difficult. The problem of how most fairly to regard licensed practitioners in Massachusetts who are not graduates of recognized medical schools and who wish to join our society is, indeed, a perplexing one.

During the last ten-and-a-half years 251 graduates of such schools have been admitted to fellowship in the Society as follows

YEAR	NO OF CANDIDATES
1928	22
1929	16
1930	20
1931	19
1932	25
1933	27

1934	22
1935	26
1936	24
1937	27
1938 (May meeting only)	23

Nowadays no Massachusetts hospital approved for intern training can have on its staff a physician who is not a member of the Society. Apparently because of this rule, increasing pressure is being put on the committee. At our last meeting we interviewed 42 candidates. The majority of them had been in practice for a minimum of five years and almost all presented enthusiastic letters from a number of fellows of the Society recommending that their credentials be accepted. In spite of the publication of the names of these candidates in the *Journal* before our committee met, we received almost no information pointing to a given candidate's unfitness.

In brief, so far as can be judged by the experience of the last decade, it is the policy of the Society gradually to elect an increasing number of members who have graduated from unrecognized or foreign medical schools. If this impression is incorrect, there now are pathways open by which confidential information concerning candidates can be submitted to proper authorities of the Society. Our committee must obey the by-laws as they are written and recognize diplomas submitted if they fulfill the requirements of the Society, unless specific information is given us concerning the undesirability of any prospective candidate.

A year ago the Council on Hospitals and Medical Education of the American Medical Association inspected the hospitals approved for intern training in Massachusetts. This council has been kind enough to submit its report to us so that our committee has on file the results of this inspection.

Interns, on the whole, appear to be receiving a fairly good training in Massachusetts. There still is a tendency for the better students to concentrate in the teaching hospitals, and for the less promising students to obtain rotating internships in the smaller ones. Many of the rotating internships continue to be too short. There still are too few necropsies performed in many hospitals. In certain institutions, work of high caliber from the intern is impossible because the amount of work to be done is so great and the number of interns to do it is so small.

Our committee has kept abreast of the Society's work in postgraduate education. This continues to be an important project. We hope that it may go forward and be well supported by all fellows. As is stated in our Code of Ethics, physicians should encourage sound medical learning and uphold in the community correct views of the powers and limitations of the science and art of medicine. There is no more effective method to fulfill this high purpose than by improving postgraduate education and by rendering it easily available to all physicians.

C. A. SPARROW,
E. S. CALDERWOOD,
A. W. STEARNS,
F. S. KELLOGG,
R. FITZ, *Chairman*

through a subcommittee consisting of Dr. Richard M. Smith (chairman) and the chairman of the Society's Committee of Public Health. Dr. George C. Shattuck has been elected president of the Massachusetts Central Health Council, the constitution and by-laws of which are being revised. This body, which is eager to co-operate with the Massachusetts Medical Society and the membership of which comprises nearly all the public, professional and lay agencies in Massachusetts concerned directly or indirectly with health, should be able to exert a helpful co-ordinating influence in the organization of the community health centers being promoted by the American Medical Association and approved by the Council of the Massachusetts Medical Society. So far as we can discover, there is no suggestion of any desire on the part of the Massachusetts Central Health Council to act in other than a co-operative manner in furthering the establishment of such community health centers.

2. The secretary of the Massachusetts Medical Society has referred to the Committee on Public Health an interesting communication from Mrs. Harriet Treat Hanson, chairman of public health, Massachusetts State Federation of Women's Clubs. This communication reads as follows:

To the Members of the Massachusetts Medical Society

The Division of Public Health of the Massachusetts State Federation of Women's Clubs is actively interested in the campaign to eliminate, so far as possible, the diseases, syphilis and gonorrhea. Recognizing the medical profession as the leading instrument through which control may become effective, this committee presents the following resolution for your consideration. This resolution has the endorsement of one hundred and sixty-three clubs representing about 23,000 women.

This resolution is drawn with the intent of gaining the co-operation of layman and doctor alike in preventing congenital syphilis. We feel that a dignified, educational, professional treatment of the problem is to be preferred to one of legislative intent. It is with full recognition of the rights and privileges of the physician to use or reject this suggestion that we present it to you. We have no intention of infringing upon the personal rights of either patient or physician.

Therefore, since we have been given to understand, from recognized authorities upon this disease, that if syphilis is detected in the pregnant woman sufficiently early, and if, when detected, is treated there is a strong possibility, in most cases, that the child will be born free of the disease,

We the members of the following one hundred and sixty-three federated women's clubs do resolve that we favor a serological test being made part of the routine examination of every pregnant woman by her physician. [A list of the clubs then follows.]

Respectfully submitted,

[Signed] HARRIET TREAT HANSON,
Chairman of Public Health
Massachusetts State Federation
of Women's Clubs.

The following joint resolution was unanimously passed by the Committee on Public Health and the Subcommittee on Public Education and a copy sent to the secretary of the Section on Obstetrics and Gynecology, with an accompanying letter requesting its consideration by the section and expressing the hope that similar favorable action would be taken by the section.

APPENDIX NO 7

REPORT OF THE COMMITTEE ON PUBLIC HEALTH

The Committee on Public Health of the Massachusetts Medical Society and the Subcommittee on Public Education beg leave to submit the following report:

1. The Committee on Public Health has been in close touch with the Massachusetts Central Health Council

RESOLVED, that the Committee on Public Health and the Subcommittee on Public Education unanimously welcome the interest and support of the one hundred and sixty three women's clubs of the State of Massachusetts in the resolution presented by Mrs. Harriet Treat Hanson, chairman of public health of the Massachusetts State Federation of Women's Clubs, favoring a serological test in the detection of syphilis, particularly in pregnant women, and heartily approve of the suggestion urging the continuance and extension of this practice to include all such cases

3 The Subcommittee on Public Education has continued to endeavor to make as useful as possible the radio broadcasts on health announced as Green Lights to Health and sponsored by the Massachusetts Medical Society and the Massachusetts Department of Public Health. A still more favorable time has been assigned to these broadcasts, which are now delivered on every Wednesday evening from 8 15 to 8 30 over Station WAAB and the Colonial Network. Every broadcast thus far delivered has evoked requests for copies which by arrangement with the Department of Public Health have been mailed. These requests have varied from 7 to 71 (Heart Disease by Dr. William H. Robey), and the numbers have materially increased as the series has progressed. We are informed that a fair index of the size of a radio audience may be roughly estimated by considering that each request represents 1000 listeners. Thus far over 700 of these so-called fan letters have been received and it would seem probable, therefore, that over 700,000 people have been reached by one or more of these broadcasts. Requests for copies of the complete series have been received from several distant states. The committee believes that this evidence suggests the wisdom of continuing with the effort. The Subcommittee on Public Education desires to again thank the fellows of the Society for their willingness to prepare these broadcasts and to accept in such a co-operative spirit the few suggestions of the committee as to the form and content of their presentation.

ROBERT B. OSGOOD, *Chairman*
GERALD HOFFEL, *Secretary*

APPENDIX NO 8

REPORT OF THE COMMITTEE ON MEDICAL DEFENSE

Our committee reports for the year about the same state of activity, or lack of it, as last year. We have had one new case, defense of which we have taken on. We have had two verdicts—both in our favor—during the year.

I took up the matter of perhaps giving up the defense of members at the last meeting of the Council. Since then, I have written to all the members of our committee and find that a majority disagree with me. No other member of the Council wrote me a word about my suggestion so I withdrew it.

There are many other things that come up besides the actual defense of cases, and I have given a number of men advice where suits have been threatened.

We have had the first result of the new arrangement about employment of counsel, and one doctor has taken advantage of the facts that a doctor is allowed to choose his own counsel and that the Society will pay the bill subject to its approval by the chairman of our committee. There is no bill as yet so I have had no argument over it. I am rather glad that the committee felt that the pro-

tection should not be given up, as I think the effect on people who bring suits in the hope of having them compromised is excellent when they find that the Massachusetts Medical Society defends but pays no verdicts. It is a most discouraging situation when they realize that even if they win they may not collect a cent.

Members who have been asked by our attorneys to testify as experts have been most obliging about doing so, and our committee feels sure the Society is most grateful to them.

FRANKLIN G. BALCH, *Chairman*

APPENDIX NO 9

REPORT OF THE COMMITTEE ON POSTGRADUATE INSTRUCTION

Since the autumn of 1937 the committee has organized a faculty and provided extension courses in postgraduate instruction for the entire medical profession of the Commonwealth. This has been done in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service, and the Children's Bureau, United States Department of Labor. The committee wishes to report that the co-operation of these government agencies has been very helpful in every respect, and it wishes to take this opportunity to thank Dr. Henry D. Chadwick, of the State Department of Public Health, for his personal interest in helping to make the program a success.

The attendance record of the districts for the past three seasons is given below. The tabulation shows an increase in attendance of 35 per cent over last year. The committee feels that this attendance out of a total of seven thousand doctors should be increased. Every doctor in the respective districts received a copy of the program in advance of the meetings, and the courses were given without charge. Most of the district chairmen report that they anticipate increased interest next year.

The committee wishes to express the appreciation of the Society for the excellent work of the faculty. The chairman of each course and each instructor gave much time and thought to methods of improving the technique of postgraduate teaching. The committee arranged with the Harvard Graduate School of Education for consultation service in pedagogy, Dr. Warren C. Seyfert of this school gave lectures and personal conferences to the faculty.

The Society appropriated one thousand dollars toward administration expense while the government agencies have contributed sufficient funds to cover other expenses, another financial report will be made at the next Council meeting. This program was made out with the idea of continuing it for three years. The committee has made out a new curriculum along similar lines for next season and is planning a budget for the consideration of the Massachusetts Department of Public Health and the other government agencies.

The Executive Committee has discussed the possibility of having a Clinical Congress some time during the fall with the idea that such a congress would be correlated with the current extension courses. It is recommended that the Massachusetts Medical Society sponsor such a clinical congress.

The committee recommends that the Society continue to co-operate with the government agencies in giving extension postgraduate courses and that the committee be continued.

APPENDIX NO 10

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations has held two meetings since its report to the Council in February, considering among other things the Lane Resolution, district health councils and the American Medical Association Survey, and immunization programs

The several districts are, with success perhaps varying directly with the effort expended, attempting to increase the amount of immunization done by the family physician. It is encouraging to hear that 30 per cent of this work in Boston is now done by him

The Lane Resolution was referred to us by the Council for study and recommendations, and the committee yesterday voted as follows

- 1 The Committee on Public Relations recommends that the Council approve the following resolution (with the proviso that as this resolution affects the specialties known as pathology, roentgenology and anesthesia, it be held in abeyance for the time being)

RESOLVED, That we approve the prepared hospital plan with the stipulation that the contract benefit provided by group hospitalization insurance shall be limited to hospital accommodations such as room, bed, board, operating room facilities, and general nursing care ordinarily provided by hospitals, routine drugs, and the routine services of interns only when acting under the direction of the attending physician, and that except as stated above, the contract shall not include the services of physicians either general or special.

The term "physician" as used here shall be understood to include all licensed practitioners holding the degree of Doctor of Medicine, who assume on their own account to interpret laboratory and x-ray findings in terms of disease and diagnosis, or to administer or direct treatment.

- 2 The committee urges the Council to recommend that the organized anesthetists, roentgenologists, and pathologists take up with the Hospital Council of Boston and the New England Hospital Associa-

tion certain very important fundamental problems in medicine related to this discussion, with the hope of reaching a decision which will be mutually agreeable to the hospitals and organized medicine.

- 3 The committee recommends to the Council that it approve the survey the American Medical Association is making on the adequacy of medical care and further recommends that the Massachusetts Medical Society accept responsibility for the proper analysis and tabulation of the material collected by the district societies

ELMER S BAGNALL, *Secretary*

APPENDIX NO 11

REPORT OF THE COMMITTEE ON PHYSICAL THERAPY

The Committee on Physical Therapy is largely concerned with education—both of the graduate and of the undergraduate—and is deeply interested in attaining the following three objectives

- 1 For the undergraduate medical student, we hope there may be instruction in this branch of medicine in all our medical schools in the immediate future. It is of definite, practical importance to all physicians to know the limitations as well as the value of physical therapy measures, and the need also for scientifically controlled investigation in this field. If this possibility is denied the medical student, he is prone to depend largely on the commercial salesman for whatever information he may acquire.
- 2 For those who are already in practice, this committee will be glad to furnish programs for medical society meetings. Talks can be given concerning the fundamentals of those types of treatment having a practical bearing for the general practitioner, or whatever aspect of the field seems most interesting to the members. During the past three years, we have provided programs in various parts of the State and would be happy to confer with anyone interested. This matter appeals to us as of very definite importance. Physical therapy appears to be less generally recognized and developed here in the United States than in England and the Continent, where it commands the interest of the most highly reputed physicians and medical organizations.
- 3 For both the undergraduates and the graduates, your committee hopes for a further development of physical therapy clinics, to include all the teaching hospitals of Boston. Such clinics should be available to the undergraduates for elementary observation, and also to them could come the graduates as visitors or students. In these clinics should be carried on practical and research work, which should be undertaken, in co-operation with the various other departments of the hospital, along scientific lines.

Such a program as we have here outlined would go far toward the education of us all in emphasizing the importance of this branch of medicine. It is the desire of your committee to be of as great assistance as possible in presenting what has proved to be of definite and practical value in this type of therapy. However, we can do but little without your help. May we have your co-operation in this program?

GEORGE R. MINOT,
FRANKLIN P. LOWRY, *Chairman*

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

CASE 24261

PRESENTATION OF CASE

A thirty-nine-year-old, white, American lawyer entered the hospital with the complaint of slight dyspnea of three years' duration.

About seven years before entry he began to have a slight dry cough which persisted practically unchanged up to the time of entry. About three years before entry he noticed that he was inclined to be slightly dyspneic. This also persisted. During the three years he had four attacks of discomfort in his chest characterized by a feeling of heaviness and compression. These were accompanied by a "cold" without fever, and they lasted two or three weeks. His past history and family history were essentially negative, and he had no other cardiorespiratory symptoms.

Physical examination revealed a well-developed and nourished man in apparent good health. The pupils were symmetrical and reacted to light and accommodation, and there was no lid drop. The left lobe of the thyroid was slightly smaller than the right. The heart and lungs were negative except for questionable dullness at the right apex posteriorly. The blood pressure was 150 systolic, 110 diastolic in the right arm, and 125 systolic, 85 diastolic in the left arm. The abdomen was negative.

The temperature was 98°F., the pulse 82. The respirations were 20.

The urine examination was negative. An x-ray of the chest showed an irregular area of density measuring about 7 cm. in diameter occupying the medial aspect of the apex of the left lung. The center of this shadow was posterior to the trachea but about opposite the vertical axis of the body. Its anterior and inferior margins were sharp in outline and definitely nodular. This appearance was accentuated by a sharply defined linear area of diminished density simulating fatty tissue, which adjoined the inferior margin. The shadow did not obliterate all the air in the lateral aspect of the left apex. Within the shadow there were areas of calcification measuring 1 to 5 mm. in diameter, some of which appeared to form part of the margin. They did not shift in position. The trachea and esophagus were apparently in contact with the medial aspect of the shadow but were not

displaced. There were questionable pressure defects on the posterior aspect of the trachea and on the lateral aspect of the esophagus. The regional ribs and vertebrae were normal, and there was no involvement of the mediastinum near the arch of the aorta or at the lung roots. The remainder of the lung fields was clear.

An operation was performed on the day of admission.

X-RAY INTERPRETATION

DR. AUBREY O. HAMPTON: I cannot add much to the description. I can merely point out the things that were mentioned. The mass is definitely nodular as you can see better here in the lateral view. There is some calcification in the periphery, some concentrated in the center and some scattered in rare local deposits, which are somewhat round. These calcified areas did not shift in position, ruling out the possibility that they were calcium granules within a fluid-containing mass. The absence of deformity of the trachea was quite impressive to me as I examined the patient. We thought of tumor of the thyroid because of the character of the calcification, location of the tumor, and so on. But a tumor of the thyroid of that extent should deform the trachea and esophagus. When Dr. Holmes saw these films he said the calcification and shape of the mass were similar to an osteochondroma. We had no other evidence, and nothing further to offer as diagnostic possibilities.

DR. JOHN W. STRIEDER: * On the basis of the films could you place the tumor within the lung?

DR. HAMPTON: That would be very difficult to answer, and yet, if you consider that it seems to be surrounded by lung anteriorly and posteriorly, it would have to be either a pedunculated tumor which has invaginated into the lung or a tumor which arises within the lung.

DR. STRIEDER: There is a definite pressure defect in the esophagus?

DR. HAMPTON: The esophagus seems to be displaced toward the mass and just shows this slight concave defect which is not definite.

DIFFERENTIAL DIAGNOSIS

DR. STRIEDER: With the x-ray evidence of intrathoracic tumor the discussion resolves itself into one along more or less broad philosophical lines and one has to run the gamut of most of the tumors of the thorax. However, the fact that there is definite calcification within the tumor is very significant, because it narrows down our differential diagnosis considerably.

*Assistant in surgery, Harvard Medical School; visiting surgeon, Massachusetts Memorial Hospitals; associate surgeon, Boston City Hospital.

Given an intrathoracic tumor, however, I think the differential diagnosis depends largely upon the x-ray. In running over some of the possibilities we can divide them into inflammatory and noninflammatory types. In the first place, aneurysm with calcification is a possibility that must be considered, but the facts that it is not in relation to the arch of the aorta and that other findings were not present on physical examination seem to me to place it outside our consideration. We have no supporting evidence from fluoroscopy, and the result of the Hinton test is not noted. The fact that there is a difference of blood pressure in the two arms is not conclusive, because pressure from without upon a vessel might give such a finding.

Old pulmonary abscess with calcification is also a possibility. The location is a little unusual, and nowhere in the history has there been an episode of an acute febrile attack from which there arose quantities of purulent foul or nonfoul sputum, also, the temperature was normal, but it may well be in a situation such as this. However, I think we can exclude pulmonary abscess. Mediastinal abscess is rare. There was no fever and there are no bone changes, which would exclude pyogenic or tuberculous mediastinal abscess.

So far as tuberculosis of the lung itself goes, such a picture is possible but not probable. We have seen circumscribed lesions with calcification on a tuberculous basis. There is no other evidence of tuberculosis in the lung fields and, in addition to the history, this is the greatest single factor in excluding it.

Could it be an encapsulated empyema? There is no history of an acute febrile episode, and the location of such an encapsulation would be unusual, to say the least.

Echinococcus cyst I mention only in passing. It is a possibility but so extremely rare in North America that we can exclude it.

As for neoplasm, dermoid cyst would be a possibility if the tumor had a pedicle which permitted it to wander somewhat. However, the facts that the trachea is not displaced and that there are only moderate pressure defects of the esophagus seem to militate against it. I cannot rule it out. Substernal goiter, of such size and location, one would expect to be associated with some changes in the trachea. Also, it lies posterior to the trachea, which would be an unusual place for thoracic goiter, although they are apt to be migratory in character. Neurofibroma is also a possibility, but there is no bone destruction. I do not know how significant calcification, in general, is in neurofibroma. My impression is that it is not common. Tumors of the rib or bone, such as osteoma, osteochondroma or osteosarcoma, can be ruled out on

the basis of the history and the x-ray findings. There was no evidence of bone destruction or bone involvement. A tumor of the lymphoma series is a possibility, although such a discrete lesion and such a location I think make it unlikely. We have no information as to the blood picture but that in itself probably would not be very much help. I question the appearance of calcification in a Hodgkin's tumor. Primary pleural tumors are rare and I think there is nothing about this case to suggest one. Lipoma of such a size within the thorax would give some alteration of the interspaces if it presented through the thorax, as we might expect it to do. So much for extrapulmonary neoplasms.

Of the intrapulmonary neoplasms, by far the commonest is bronchiogenic carcinoma. This man's history does not suggest it. There should have been some blood spitting or streaking of the sputum with blood. Moreover, a tumor of this size ought to cause some general symptoms, and the presence of calcification within the tumor makes it rather unlikely in my opinion. Benign tumors of the lung are exceedingly rare, by far the commonest of these is chondroma, arising primarily in the lung, as distinguished from adenoma of the bronchus with calcification of the stroma, which does occur. A primary chondroma of the lung is perhaps the commonest of the lung tumors if one excludes bronchiogenic adenoma and carcinoma, and my inclination has been to consider chondroma quite seriously. I was interested to hear that Dr. Holmes thought about it in somewhat the same way. Adenoma usually occurs in relation to one of the larger primary or secondary bronchi, and before it attains this size should give symptoms of suppuration, due to stenosis by encroachment on the lumen of the bronchus from which it arose.

We have no evidence to assume that this is a metastatic tumor. I have seen a solitary metastasis from hypernephroma which was much the same but had no calcification in it.

I dislike "digging so far down into the bag" to make a diagnosis of a rare tumor, but I think the descriptions that have been reported by Hickey and Simpson of primary chondroma of the lung which have lobulated borders and areas of calcification, and the fact that there is rarefaction at the border of this tumor, to my mind make it a likely diagnosis. I should like to place chondroma of the lung as my first diagnosis. I cannot rule out a dermoid cyst, and I cannot be sure that substernal goiter is not a possibility.

CLINICAL DISCUSSION

DR. EDWARD D. CHURCHILL: We despaired of giving an accurate histologic diagnosis. The gen-

eral practical problem involved was how to approach this tumor. If it were a substernal goiter it might have a large vascular pedicle coming down from the inferior thyroid artery. In such a case a cervical incision would aid in control of the blood supply. If it were a *neurofibroma* it should be approached posteriorly. If it were a primary tumor in the lung apex we should prefer to make an anterior approach through the chest. We worried a good deal as to whether we should place our incision correctly, but weighing all the evidence decided to approach through the anterior chest wall at the level of the third rib. I think probably an artificial pneumothorax for diagnostic purposes would have helped us. It might have shown more definitely whether the tumor was in the lung or mediastinum. A good deal of the evidence that the x-ray department is now bringing out is given in retrospect, and if I recall the situation accurately, Dr Hampton really thought it was a substernal goiter. At any rate, we chose an anterior incision which proved to be the correct one as the tumor did arise in the apex of the lung and was attached by only one adhesion to the mediastinum.

DR TRACY B MALLORY: Do you want to describe the gross findings, Dr Churchill?

DR CHURCHILL: The tumor was situated in the extreme apex of the thorax and was adherent at only one point. After severing this adhesion it could be lifted from the chest, bringing the apex of the lung with it. The surface of the tumor was white and glistening and resembled a piece of coral. Its appearance called to mind certain ovarian tumors with papillary projections from the surface. Its removal required resection of a small piece of lung tissue in the apical region.

The condition of the parietal pleura was interesting in regard to the symptoms. There was definite evidence of chronic pleuritis probably resulting from mechanical trauma from the tumor. The pleura was thickened and there was heavy fatty infiltration under the parietal pleura. I think his sensations of pressure and pain at the apex were undoubtedly due purely to the mechanical trauma of the tumor on the parietal pleura.

PREOPERATIVE DIAGNOSIS

Calcified adenoma of thyroid?
Primary tumor of lung?

DR. STRIEDER'S DIAGNOSIS

Chondroma of the lung

ANATOMICAL DIAGNOSIS

Hamartoma of the lung

PATHOLOGICAL DISCUSSION

DR MALLORY: The tumor proved to be what Dr Strieder predicted, usually called a chondroma. There has, however, been a good deal of discussion in the literature as to how these tumors should be classified from the pathological point

The coral-like mass of cartilage and glandular tissue found at the apex of the left lung

of view. We wound up by making a diagnosis which is probably an unfamiliar one to most of you. We called it a hamartoma. The term was suggested by Albrecht in 1905. I thought it well to bring along the definition.*

Hamartomata are tumour like malformations in which occurs actually only an abnormal mixing of the normal components of the organ. The abnormality may take the form of a change in quantity, arrangement or degree of differentiation, or may comprise all three. The deduction to be drawn from histological examination of these formations is that they have originated in an abnormal mixing of the elements or from disturbances of their development.

This tumor on histological examination is made up mostly of cartilage with foci of calcification in it, but between the many small masses of cartilage is a loose areolar fibrous tissue containing cyst-like spaces. The latter are lined with epithelium, the majority of which is low and cuboidal, but in two or three places definitely tall, columnar and ciliated, in other words characteristic respiration epithelium, so that the tumor is a mixed tumor and not a true chondroma. One might ask why it is not a teratoma. A teratoma is theoretically a tumor arising from misplaced germ cells that have the potentiality of differentiation toward all forms of tissue that can be found in the body. In a teratoma one gets hair, squamous epithelium,

Goldsworthy N. E. Chondroma of the lung (hamartoma chondroma iustum pulmonis) with report of a case. *J Path. & Bact.* 39:291-298 1934

possibly neuroglia, nerve cells, and so on. In this case we have no elements present except the elements that are normal in lung tissue, and therefore it seems to fit perfectly into this definition of hamartoma. The diagnosis is made in other organs as well. In children one may occasionally see a hamartoma of the liver made up of large collections of liver cells and bile ducts without normal liver architecture.

DR HAMPTON: Is there any explanation for the line of diminished density medial to the tumor which looked like fat?

DR MALLORY: These tumors have been reported to contain fat in a number of instances. We found a few fat cells in this one but not a large enough amount to account for the x-ray findings.

DR CHURCHILL: It might have been fat under the mediastinal pleura.

DR HAMPTON: That was what I had in mind.

DR CHURCHILL: A protecting fat bed was present around this tumor subpleurally.

DR HAMPTON: That was the peculiar part of the whole thing to me. I did not mention it today because I thought it would only be misleading.

DR STRIEDER: In the cases reported by Hickey and Simpson they lay great stress on this linear shadow of decreased density. The two tumors they have described as chondroma were probably hamartomas because the histological description of this case as given by Dr. Mallory fits very well with what they reported.

CASE 24262

PRESENTATION OF CASE

An eighteen-year-old, white, American housemaid entered the hospital with the complaint of abdominal pain of three days' duration.

Three days before entry on waking in the morning she noticed steady, sharp, stabbing pain in the epigastrium, right-lower quadrant and right flank which persisted unchanged in intensity and character until the time of entry. It was sufficiently severe to keep her awake at night but for the first two days did not confine her to bed. On the morning of the day before entry her physician put her to bed and prescribed hot fluids by mouth, which apparently had no effect on the pain. She had some anorexia with occasional nausea, but no vomiting. During that day she had two shaking chills, but she said she did not feel feverish. During her illness she also had frequency, severe dysuria, and nocturia six or seven times each night, but no hematuria. She had no vaginal discharge, and her bowels moved regularly. She had photophobia which she had also had for a period of a month four months previously. Her menstrual pe-

riods had begun at the age of twelve and except for mild cramps were regular and normal up to one year before entry, when they ceased entirely. Two years before entry she had had a vaginal discharge which was adequately treated at an outside institution and cleared up in three weeks. For about seven years she had had a chronic unproductive cough accompanied by slight chest pain. There was no family history of tuberculosis, but at one time chest x-rays were taken of both her and her sister by the state health department. Her past and family histories were otherwise noncontributory.

Physical examination revealed a fairly well-developed, well-nourished girl complaining of pain in the right lower quadrant. An eye consultant could find no evidence of disease in the eyes and treated the photophobia with drops. The heart and lungs were negative, and the blood pressure was 108 systolic, 60 diastolic. There was marked tenderness in the right side of the abdomen, most marked in the right-lower quadrant with questionable spasm. A lemon-sized mass which was thought to represent the cecum was palpable in the right-lower quadrant. On pelvic examination the introitus admitted two fingers. There was tenderness in both vaults, more marked on the right, with a questionable mass on the right. The fundus of the uterus was displaced anteriorly and was freely movable.

The temperature was 98.4°F., the pulse 78. The respirations were 20.

The urine examination was negative. The blood showed a white-cell count of 15,700 which fell to 12,800 in the next eighteen hours. The blood Hinton test was negative, and the nonprotein nitrogen was 25 mg per cent.

An intravenous pyelogram showed normal kidney pelvis, ureters and bladder. The kidneys were visible and appeared to be rather small. Scattered throughout the abdomen were numerous irregular areas of calcification having the appearance of calcified tuberculous glands. No stones were demonstrated.

On the third day the white-cell count was 13,800 and on the fourth day 12,000.

A laparotomy was performed on the fourth day.

DIFFERENTIAL DIAGNOSIS

DR LANGDON PARSONS: This is obviously a history of an acute abdominal condition which came on suddenly and was of only a few days' duration. The pain was steady and sharp, without acute exacerbations, and was in the mid-epigastrium and the right-lower quadrant and flank. One interesting feature is that there was no relief of pain on

lying down. It was worse at night. Apparently there was no general systemic reaction because she was up and about. She had occasional nausea, but apparently no vomiting. She had two shaking chills, and also frequency, dysuria and nocturia. If one takes just the history alone one can think of three or four diagnoses. It could be, of course, a smoldering case of appendicitis, although there are certain definite things against that, such as the steady character of pain and failure to localize after three days, and the fact that there was no story of fever. The only temperature recorded was the normal one on admission. One could also work out a good case for urinary infection, with the frequency, the dysuria and the right-flank pain. The intravenous pyelogram was negative, however. The white count of 15,000 would be consistent with either of these possibilities. Also an ovarian cyst would fit into this picture perfectly well on the basis of the early acute history. If it were an ovarian cyst I should rather believe it was a cyst that had ruptured rather than a twisted cyst, and the urinary symptoms might come from peritoneal irritation or from pressure.

In the past history I do not know how to explain the photophobia which she had for a month. There are no signs on physical examination to give a lead as to what it might have been. The eye consultant could find nothing. There may be an association with the amenorrhea which came on after five years. Since there is no history of drugs, iodism or anything else, it cannot be explained on a toxic basis. The amenorrhea is of considerable interest. Her menstrual periods started at twelve and were normal up to the age of seventeen, one year before entry, when they ceased entirely. There are no other suggestions on physical examination or in the history to suggest a pituitary type of failure or thyroid deficiency, or any difficulty with the thyroid itself. One would have to think that this was a primary ovarian type of failure of some sort. The vaginal discharge does not amount to much, perhaps it was due to *Trichomonas vaginalis* and cleared up under treatment.

She has suggestive but unproved tuberculosis. She had a history of unproductive cough for seven years, with chest pain, but there is no family history of tuberculosis. She had a chest plate but they do not tell us what it showed.

DR. TRACY B. MALLORY: The chest plate was reported negative.

DR. PARSONS: On physical examination there is definite tenderness in the right lower quadrant with questionable spasm. The mass as described

does not help us very much. It was a questionable mass which was thought to be cecum, but we have no note as to whether it was soft or hard, tender or movable, or about its relation to the pelvic mass, which was also questionable. On pelvic examination there is tenderness in both vaults. The most interesting feature about the pelvic examination is the statement that the uterus was displaced anteriorly. They say nothing about the uterus's being in anterior position. They simply have noted that it was displaced anteriorly and that suggests displacement from the presence of a mass behind the uterus. A questionable mass in that region, with the tenderness, would tend to localize the difficulty pretty well in the pelvis. The abdominal plate which showed calcified glands may or may not have some bearing on this picture.

If I were confronted with this problem and had to operate I should make a midline incision. If pressed for a diagnosis, I should tend to state that there was a tuberculous salpingitis, which one could work out on the basis of questionable chest lesions of the calcified mesenteric glands, of the amenorrhea extending over a period of years and of the very questionable mass behind the uterus. I cannot help believing, however, that we are dealing with an ovarian cyst which has perhaps ruptured, thus accounting for the acute abdominal symptoms, and I still have the diagnosis of appendicitis in the back of my mind.

DR. WILLIAM B. BREED: Was there any displacement of the psoas muscle by x-ray, Dr. Holmes?

DR. GEORGE W. HOLMES: The muscles are not very clear on either side, but I should think they are negative.

DR. A. THORNTON SCOTT: What are the peculiar shadows in the upper corner, low in the pelvis and overlying the midsacrum?

DR. HOLMES: It is possible that they are mesenteric nodes low in the pelvis. They are a little large for phleboliths, and I do not believe they are stones in the ureter or bladder. They are outside the bladder and not in the ureter. A stone that size in the ureter would block it.

DR. SCOTT: Could they be contents of a cyst?

DR. HOLMES: One ought to think of dermoid, but there is nothing characteristic about the shadows and no other soft-tissue mass around them.

DR. BREED: I should like to ask how often rupture of an ovarian cyst occurs.

DR. PARSONS: As I have reported here before,

I was rather struck with the fact that in 120 consecutive cases of endometriosis, not all with ovarian involvement, 20 came into the hospital with an admission diagnosis of acute abdominal disease and most of these were proved to have rupture of the cyst. Follicular cysts also may produce symptoms when they rupture, but rupture of cystic neoplasms of the ovary is certainly uncommon.

PREOPERATIVE DIAGNOSIS

Calcified mesenteric glands

DR. PARSONS'S DIAGNOSIS

Ruptured ovarian cyst

ANATOMICAL DIAGNOSIS

Tuberculous salpingitis

PATHOLOGICAL DISCUSSION

DR. MALLORY This patient was explored by Dr. Claude E. Welch. He made a right rectus incision and found many enlarged, some soft and some calcified mesenteric glands. Both ovaries and tubes were bound tight to the posterior surface of the uterus and several spots of gross caseation were found in the wall of the tube, so he made a diagnosis of tuberculous salpingitis. This was confirmed in the laboratory. The cecum was entirely normal so far as he could make out on examination.

THE BRITISH HEALTH SERVICES

A GROUP of more than one hundred Englishmen under the designation PEP (Political and Economic Planning) has been engaged in fact-finding studies and "in suggesting principles and possible advances over a wide range of social and economic activities" in Great Britain.

Ten volumes have been published by the group, and its continuing investigations are set forth by supplementary fortnightly broadcasts carrying accounts of work underway with findings and commentaries on selected sociologic and economic problems.

Under the direction of PEP more than two hundred persons and organizations have devoted over three years to a study of British health services. In December, 1937, the results of these investigations were published, with appropriate con-

clusions and recommendations, in a volume¹ of four hundred and thirty pages. This is the most voluminous and probably the most important of the ten reports.

In explanation of the complicated public-health activities of England now in operation, there are detailed accounts of every agency engaged in the administrative functions connected therewith, together with reports of contemporary official and voluntary bodies connected with organized medicine, dentistry and nursing.

The opinion is expressed by PEP that the average doctor is so occupied with the care of illness that, except among especial groups, little attention is bestowed on the causes of illness, with the result that the hiatus existing between curative and preventive medicine has not been adequately bridged. This explains to some extent the unsatisfactory situation relating to the existing health-administration system,—or rather many systems which theoretically interlock,—which according to PEP fails of desired results because of inherent complications incident to overlapping and uncoordinated procedure by many departments that include some health problems requiring professional services or opinions, such as, industrial health insurance, education, housing and venereal-disease control. To remedy existing conditions PEP asks "What are health services?" evidently hoping to differentiate administrative and medical-service functions, but one cannot find that the attempt to answer clarifies the situation.

In commenting on this phase of existing conditions the editors² of the *Lancet* contend that every agency should be enlisted to help promote good health (this is axiomatic) and so relieve the health services proper of congestion, overwork and poverty, and particularly that the general practitioner should recognize his strategic position for making the resources of such services available in dealing with the peculiarities and needs of the individual consumer of health services. We confess to a little confusion with respect to the application of these suggestions which may be due to inability to understand the situation in Great Britain, and when one reads Chapter V of the report, devoted

to "The Medical Profession," and learns of the duties and responsibilities of the registered doctor in that country,—acting, as most of them do, as agents of the government in one capacity or another, or engaged in fields unassociated with health work,—the likelihood of the general adoption of the latter suggestion seems somewhat remote

Both the *Lancet* and PEP agree that there is room for improvement in the medical service under National Health Insurance, with extension to include more consideration of individuals, and especially a co-ordination of the agencies for attacking disease and disability

Further confirmation of the criticisms of the British health administration is furnished by the *British Medical Journal*—the official organ of the British Medical Association, which, in its reference³ to the survey by PEP, states "This survey is more comprehensive in its range than anything that has yet been done and more frankly, though constructively, critical of the chaos in which the many independent and sometimes conflicting health agencies operate"

As one reads the several reports included in this survey and the confirmatory opinions relating to the facts, conclusions and recommendations submitted, it is apparent that there is dissatisfaction in the minds of the medical profession and public-spirited citizens with the existent health services in that country and that there are now before the British government alleged facts and suggestions which seem to demand action

It may be fair, however, to turn the shield about and see the other side. One finds that England has accomplished a great deal in efforts to improve social conditions, safeguard health and bring the resources of medicine to bear on the ills of her people. The question seems to be largely that of organization and application

PEP has certainly placed before the world suggestions for ideals of service and methods of procedure which warrant consideration not only by Great Britain but by other countries as well

MEDICAL LIBRARY ASSOCIATION

THE Medical Library Association's meeting in Boston on June 28, 29 and 30 celebrated the completion of forty years' existence of the association. Organized in Philadelphia in 1898 with eight charter members, the association has grown until, at the present time, it has a membership of over five hundred and is international in scope. It ranks in importance with such associations as the American Library Association and the Special Libraries Association. During the past ten years, it has been actively engaged in a campaign to reduce the excessive cost of German periodicals and has accomplished a great deal in this particular endeavor, resulting in a great saving to medical libraries of the world.

Such men as Sir William Osler and Dr James Read Chadwick and Dr John Woodford Farlow, of Boston, have served as presidents of the association. The association had met in Boston on three previous occasions during the presidencies of Drs Chadwick and Farlow, and at this fortieth meeting, the president for the year was James F Ballard, director of the Boston Medical Library.

The chairman of the Program and Entertainment Committee was Dr Henry R Viets, librarian of the Boston Medical Library, and the chairman of the Committee on Local Arrangements was Miss Anna C Holt, librarian of the Harvard Medical School.

CASE HISTORY No 78 PLACENTA PREVIA AFTER
VIABILITY

Mrs E. E., a twenty-five-year-old essential primipara, on February 5, when a little over nine weeks pregnant, passed considerable bright blood. She was put to bed.

The family history was essentially negative. She had had nasal diphtheria as a child and her tonsils had been removed, her past history was otherwise negative. Catamenia began at eleven, were usually ten to fourteen days late, and lasted from five to seven days, with no real pain. She had had one early miscarriage. Her last period was December 24, making her due for delivery late in September.

A physical examination on the day of bleeding showed a well-developed and nourished young woman. Her heart showed no enlargement, there were no murmurs. Her lungs were clear and resonant, there were no rales. The blood pressure was 110 systolic, 60 diastolic. A vaginal examination showed the uterus to be deep in the pelvis, the cervix soft, and the fundus in the first degree of retroversion.

A vaginal examination ten days after she had been put to bed showed no polyp of the cervix. After she had been in bed a little over four weeks she was allowed to resume her normal life.

Her pregnancy remained uninterrupted and uneventful until July 18—approximately twenty-eight or twenty-nine weeks after her last period. At this time she had a little more discharge, the uterus was not irritable, and the fetal heart was heard. In view of the previous bleeding at nine weeks she was kept quiet at home. Three weeks later, when she was about thirty-two or thirty-three weeks pregnant, she had some painless bleeding which she estimated amounted to about a cup and a half, and several hours later she passed a small clot. The uterus was enlarging normally, and the fetal heart was heard. She was removed immediately to the hospital and her blood was matched with her husband's. With rest in bed there was no bleeding until three weeks

after entering the hospital, when she began to flow very freely. She had been kept in bed these three weeks for the purpose of getting the baby to viability. No vaginal examinations had been done. The treatment was entirely conservative as the presenting part was high. The diagnosis of some form of placenta previa was made. Examination showed the uterus to be soft and the fetal heart present, she was not in labor. Cesarean section seemed to be the operation of choice, although the prematurity of the baby made its survival problematical.

A low, classical cesarean section was done without bladder reflection, the placenta was found to lie over the cervix. A 6 lb., 14 oz., female child was delivered, but died three hours later. An autopsy showed that no true primary cause of death other than prematurity could be found. Edema of the brain and atelectasis of the lungs pointed to death from asphyxia, which fact was further evidenced by petechial hemorrhages.

Her temperature remained normal, and the convalescence was uneventful. She has since had three children and was sterilized at the birth of the last one.

Comment. The conservative treatment of cases of painless bleeding before viability, if the patient can be hospitalized and if bleeding ceases, is ideal. In such cases, vaginal examination is not justifiable. It jeopardizes the lives of both mother and baby because of the probability of a hemorrhage following the examination which makes immediate delivery absolutely necessary. At operation the placenta was found over the cervix, had she been treated with a bag, much hemorrhage might have ensued, and of course the baby would have had no chance whatever.

MEDICAL ETHICS

DR. CHEEVER. Most people have an idea that the members of the medical profession are governed by a special and peculiar code of ethics, which may be admirable in its intentions but is nevertheless rather idealistic and unpractical, and sometimes makes it difficult for the patient to get exactly the attention which he thinks he ought to have.

MRS. X. It is true, Dr. Cheever, that we laymen hear a good deal about medical ethics and are sometimes rather mystified about it. But surely the conduct of an honorable physician is governed by the same principles as guide other people, isn't it?

DR. CHEEVER. Of course it is, and these principles, as so often has been said, really amount to the Golden Rule.

Doctors are often spoken of as belonging to one of the noblest of the professions, but some of us wince a little at

A series of selected case histories by members of the section will be published weekly.
Comments and questions by subscribers are solicited and will be discussed by members of the section.

A Green Lights to Health broadcast given by Dr. David Cheever on Wednesday, June 15, 1938, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

the term, because we know that we are only a cross-section of humanity, influenced by the same motives, ideals and temptations and beset by the same weaknesses as other people. In truth a profession is noble when it is practiced nobly but it is certainly base when it is practiced ignobly, and the same thing may be said of any other occupation. No doubt, there are those who practice medicine ignobly, but I think we are justified in feeling that a profession which requires such a long and expensive education, which is essentially altruistic in its nature, since its object is to relieve suffering and to restore a handicapped person to health and efficiency, which exacts such industry and hard work from its disciples and yields on the whole a rather small compensation, is one that has some, at least, of the attributes of nobility. Our code says, "A profession has for its prime object the service it can render to humanity, reward or financial gain should be a subordinate consideration. Of course this suggests that a commercial or business occupation has financial gain as its first object, and that service to humanity is less important. No fair-minded man believes that there is any such clean-cut difference, but perhaps this statement represents the idealism which has always actuated the best physicians.

There is certainly a great difference between buying services from a physician and purchasing goods from a merchant, who advertises and displays his wares in the most tempting manner and often does not hesitate to say that they are the best to be had anywhere. The prospective purchaser examines them, samples them, and moves on to the shop next door and repeats the process without creating ill-feeling. It is all in the nature of barter and exchange. He is fairly well protected against being misled, by his own knowledge and judgment of everyday things, and by the opinion of the world at large. When a person purchases services from a doctor, however, conditions are very different. The service is based on the science of medicine, of which the patient knows little or nothing. He cannot judge of the skill of the physical examination, the meaning of laboratory tests, the accuracy of diagnosis or the wisdom of treatment. In most cases, even the final result does not give a basis of judgment, because medicine is not an exact science. Moreover, much of the doctor's work must, for the sake of the patient, be performed in private, and is not subject to the scrutiny of the public at large. For these reasons mutual confidence between physician and patient is absolutely essential, the physician listens to intimate revelations and confessions, which he must hold in trust and not reveal unless required to do so by the laws concerning privileged communications, which differ in different states. Any betrayal of this trust or failure to perform his work conscientiously may mean more harm to the doctor's patients than a similar lapse to the clients of any other profession.

The ideal relation between physician and patient is much more likely to be developed if it is long continued or permanent, as in the case of the family physician or general adviser, who guides the wayfarer among medical and other pitfalls from birth to death. Of course the conditions of modern life, especially the necessary encouragement of specialists, have made such a relation almost impossible except in small communities, but the doctor has a right to expect that once he has undertaken the care of a patient he will not be dismissed unless for a very good cause.

Mrs. X. Now, Dr. Cheever, may I ask you to tell us a little more about this relation between doctor and patient? I heard the other day of a lady who sent for a cer-

tain physician and he refused to come, giving some rather flimsy excuse. Wasn't that contrary to law, or at least very unethical?

DR. CHEEVER. Do you happen to know whether it was an emergency, and whether the lady was a regular or former patient of his?

Mrs. X. No, she was not, and it was not an emergency.

DR. CHEEVER. Well, I am glad you asked the question, for there is much misunderstanding about the matter. There is no law in Massachusetts, and no regulation of the Massachusetts Medical Society, which requires a physician to respond to a call. In the words of the code of the American Medical Association: "A physician is free to choose whom he will serve." But if a real emergency exists and no other doctor is readily available, a physician should feel bound in honor to respond, and would certainly be severely criticized by his fellows if he did not do so. Furthermore, having once accepted a case he ought to feel in honor bound to continue with it until, if he has adequate cause for wishing to be released, he has given due notice to his patient so that another doctor can be secured.

Mrs. X. Another thing—sometimes it seems as though it were almost impossible to get the particular physician whom a person wishes, because medical ethics seem to stand in the way.

DR. CHEEVER. I think I can straighten you out on that very easily. In the first place, there is absolutely nothing in medical ethics to prevent a patient from seeking the services of any physician he chooses. One partial exception to this statement I shall mention later. But the confidential relations between doctor and patient and the folly of swapping horses while crossing a stream make it most unwise for a patient to keep changing physicians, especially during the course of a particular illness. In deed, as I have pointed out, a lifelong allegiance between doctor and patient has very much more than a sentimental value. Moreover, in a given community, it is most important for the general social welfare that the physicians should be on friendly terms with each other, and cooperate without jealousy in the care of the sick. Consequently we doctors feel that as our code states, "a spirit of competition considered honorable in purely business transactions cannot exist among physicians without diminishing their usefulness and lowering the dignity and standing of the profession." This means that a doctor, except in case of an emergency, should never take charge of a person known to be the regular patient of another physician, until the latter has either voluntarily given up the case, or has been dismissed by the patient. All that we doctors try to insist on is that the patient shall notify the doctor that his attendance is no longer desired and assure the new doctor that this has been done. It is wise also for the latter to inform the former that he has been called in. The exception that I spoke of is in the matter of consultations. It is of tremendous importance for the patient that there should be the utmost freedom and willingness on the part of the regular doctor to seek help from another qualified authority, but he can hardly be blamed for hesitating if he knows that he may lose his patient by so doing! For this reason it is considered unethical for a consultant to agree to a patient's request that he take regular charge. If the actual attendant asks him to do so, that is a different matter, but it is the custom of most consultants to refuse, in order absolutely to avoid any jealousy or misunderstanding and to make the regular man the more willing to seek help. Have I made the matter clear?

Mrs. X Yes, I think so Now I am tempted to ask you about fees Why isn't there a regular schedule of prices? Why do doctors often charge a varying amount for the same services to different patients?

DR. CHEEVER Well, that is a long story! In the first place, who can say what medical services are worth? Let us suppose that the doctor is an able and ambitious young man, that he has spent eight or nine years after leaving college (which is not unusual) in his studies, that he has expended and perhaps run into debt for \$10,000 in so doing, and that at an age from thirty to thirty-two he is ready to start in to build up a practice which will be terminated by a worn-out heart at sixty or by forced retirement at sixty to sixty-five, and let us suppose that, by the exercise of his special knowledge he is able to save the life of a wealthy man What are those services worth? At the other end of the scale, suppose he does exactly the same thing for the forgotten man on relief What is that worth? I am sure I don't know, but isn't it clear enough that under our present system the same fee can not be charged to all persons? For time out of mind the best doctors have been glad to give a certain proportion of their time and skill, without fee, to the care of the sick poor, and they hope to be able to continue to do so in the future if they are not interfered with by meddling some government regulation But to be more specific, I think that there should be complete frankness between patient and physician about the matter of fees The patient, if he has any doubts, and before he asks for advice or treatment, should feel free to ask exactly what expense he is about to incur, and I hope he will find that the doctor will be glad to learn whatever he cares to reveal about his financial situation, to plan the treatment and fee accordingly, or to help him, if necessary, get equally good advice and care from some younger but competent man or from some other of the readily available agencies. I might quote our code of ethics on the matter Physicians may place any value they deem proper on their services, with the understanding and consent of their patients beforehand." Does that answer your question?

Mrs. X Yes, and it reminds me of another What is all this talk about fee splitting?

DR. CHEEVER Fee splitting is an abuse which seems to have attracted attention lately, but which must be as old as the profit motive, if not so respectable. It simply means the payment of a commission, usually secretly, by one physician to another, as a reward for calling him in consultation or to perform special services such as a surgical operation. Such a practice cannot fail to lead to scandalous abuse, since it puts the premium on calling the consultant who will pay the highest commission, instead of the one best fitted for the job in hand. No decent doctor would engage in the practice, and any physician who did would be expelled from the Massachusetts Medical Society.

Mrs. X One more question along the same line. What is group practice and contract practice? Are they considered unethical?

DR. CHEEVER You must not confuse these two terms. In group practice a number of physicians who pursue different branches or specialties associate themselves together so that a patient may obtain, within the group, advice and treatment for any phase of his complaint you can see that that may save him time, trouble and perhaps expense. There is nothing unethical about that. Like anything else, it may have drawbacks—for instance, one or more members of the group may not be very competent, and yet the inducement for the patient to consult them may be very great. In general, the relation of the

group to the patient and to society should be exactly the same as that of the individual doctor Now, contract practice means that a doctor agrees to attend a number of individuals or families for a certain length of time for a fixed sum, such an arrangement is not strictly unethical, but it is not encouraged by medical societies, because practice under such conditions tends to be a cut price affair which leads to a poor grade of medical work.

Well, I suppose our time is about up, but you seem to take such a genuine interest in these matters that I wish I could discuss with you some of the many other aspects of medical ethics, for instance, why anything that savors of self-advertisement by the practicing physician is condemned, why he is not supposed to tell the world what a fine doctor he is by writing articles, about what he is doing, in newspapers and magazines or by radio addresses I daresay you can see the point! I'd like to try to explain the attitude of the doctors of the regular school toward the cults—I won't name them for fear of offending some of our radio audience! The physicians of what we may call, for want of a better term, the regular school, base their medical art on science on facts slowly accumulated through the centuries by observation, experience and experimentation They do not care where these facts come from, whether from the research laboratory or from the jungles of Peru, so long as they are able to stand the test of scientific proof. The cults, on the other hand, usually base their method of practice on some exclusive dogma or unproved theory such as that all diseases are caused by displacements of bones. It is no more possible for a doctor to consult advantageously about a patient with a cultist who believes that, than it is for you to discuss geography with a man who still believes that the earth is a flat disk!

Another matter I don't believe it is necessary to remind you that the best physicians will never have anything to do with secret remedies, and if they make a useful discovery they immediately publish it, thus giving it to the world, instead of patenting it and thus reserving it for their exclusive use. That is one of the reasons that medicine is called a liberal profession.

Well, our time is up In thinking over what I have said, I believe you can't fail to see that these principles of conduct which we call medical ethics are really designed to help the public obtain the very best medical service, which after all is the aim of every physician worthy of the name.

MISCELLANY

A SECOND U.S.P. SUPPLEMENT

At the recent meeting of the U.S.P. Board of Trustees, authority was given for the publication of the *Second U.S.P. XI Supplement*. It is hoped that this can be printed and released on January 1, 1939.

Preparation for this supplement has been under way for months, and subcommittee chairmen will be in a position in the near future to submit reports on a number of revised texts. The Subcommittee on Scope is also considering the admission of a number of additional important new drugs.

The members of the committee are fully familiar with the outstanding advantages of the interim revision and supplement features of the pharmacopoeial program. This gives the opportunity to issue new standards after they have been subjected to extensive checking in many laboratories.

The former decennial revision method compelled the consideration of between five and six hundred items simultaneously, and then at the end of the revision period

it became necessary to go to press with the entire lot, irrespective of the status of their revision. Of necessity, with some subcommittee chairmen handling from a hundred to a hundred and seventy five separate monographs, it was impossible to give each article the exacting consideration and extensive review which has been possible under the new plan by which only a dozen or so monographs are under revision at one time.

The supplement is also permitting the prompt recognition by the *Pharmacopoeia* of important new medicines, and, as indicated above, this will be a feature of the *Second Supplement*.

The U.S.P. Board of Trustees modified the original plan for the issuance of annual supplements before the *First Supplement* was issued, on the ground that a more flexible plan seemed necessary. They became convinced that in some years circumstances might make it necessary to issue a new supplement before twelve months had passed, while under other conditions an additional supplement might not be required for several years. The Board therefore announced, through the medical and pharmaceutical press, about a year ago, that new supplements would be issued whenever, in the judgment of the Committee of Revision and the Board of Trustees, conditions made this desirable.

The Board of Trustees and the Committee of Revision are responsible only for the preparation of the official standards. Whether or not the *Pharmacopoeia* and its supplements are purchased by retail pharmacists is, in some states, entirely optional. In other states where the law requires the possession of these books, it is a matter for the responsible state officials to enforce.

Finances are in excellent condition and the Board of Trustees has been able to meet the revision expenses of the decade, to increase greatly the research and conference programs, and still to hold its basic reserves intact.

In preparing the *Second Supplement*, every step will be taken to insure the carrying out of the requirements of the convention for the preparation of an official text. It is expected that the revised or new monographs will be submitted in the form of proof to members of the Committee on Revision and given wide publicity. Following their publication, a public hearing will be granted at which members of the Executive Committee responsible for revised texts will be in attendance. Following the public hearing a conference with the officials of the Food and Drug Administration and the United States Public Health Service will be held, after which the members of the Committee of Revision will be given an opportunity to see and vote upon the approved text. When the *Second U.S.P. XI Supplement* has been issued, ample time will be given before it becomes official.

SCULPTICOLOR OF FILDES'S MASTERPIECE 'THE DOCTOR' GOES TO ROSENWALD MUSEUM

The reproduction of the Sir Luke Fildes's masterpiece "The Doctor," first shown by the Petrolagar Laboratories at Chicago's Century of Progress Exposition in 1933, was recently presented by its owners to the new Rosenwald Museum of Science and Industry in that city.

Following the two world's fairs, "The Doctor" Exhibit went on a tour of 50,000 miles and was viewed by over five million people in eighteen principal cities throughout the country. Designed to remind the public of the importance of the family physician, its completion required the full time of the late Chicago sculptor, John Paulding,

The Doctor

and the noted artist, Rudolph Ingerle, and a large corps of assistants for nearly a year.

In its new location it will be seen by millions of visitors annually.

CORRESPONDENCE

PETTY POLITICS

To the Editor Relative to your comment regarding the City Hospital, are you aware that the Boston City Hospital is specifically chartered for the benefit of the indigent poor of Boston?

Would it not be a great benefit to the overburdened taxpayers of Boston if the City Hospital was cleared of the well-to-do politicians and their well-to-do friends who receive medical treatment in the Hospital proper and also in the Out Patient Department, free?

Does the editor think that city employees, with steady positions, come under the head of the 'indigent poor'?

Mayor Tobin could save plenty by restricting admissions to the Hospital, to those who come under the class of people, for whom the Hospital was chartered.

CHARLES MALONE, M.D.

46 St. John Street,
Jamaica Plain, Massachusetts

* * *

March 21, 1938

Dear Dr. Malone

I have just returned from a short vacation, and your interesting letter of March 5 has been brought to my attention. To the best of my knowledge, the executives of the Boston City Hospital, within the past few years, have made a strenuous and successful effort to eliminate 'free beds' for politicians and their friends and constituents. Furthermore, this point was adequately covered in the editorial "Pettyfogging Petty Politics" which appeared in the February 17 issue of the *Journal*.

ROBERT N. NYE, M.D.

8 Fenway,
Boston

* * *

May 22, 1938

Dear Dr. Nye

The letter I wrote was intended for publication in the *Journal*.

I with three other doctors as a committee from the Norfolk District studied for three months the hospitals in Boston, also I was one of the committee of three from Norfolk, Middlesex South and Suffolk to study the abuses at the hospitals in Boston that I was specially assigned to the City Hospital that I think I know conditions there

very well, that Dr Manary is a good man and not to blame for the rotten abuse of politicians and others who are getting free care there at the expense of the taxpayers.

I have been just wondering what the *Journal* has done to help the doctors in these trying times. One doctor tells me that he has not had a call in three months. An obstetric specialist tells me that he had two cases in 1937, that practically all his patients have gone to the Lying in Hospital.

Conditions seem to be very good for a few men at the top for the men that are in control of the *Journal* but I understand the *Journal* is supported by the general practitioner.

Your excuse for not publishing my letter is poor and not true.

CHARLES MALONE, M D

46 St. John Street,
Jamaica Plain, Massachusetts

* * *

May 24, 1938

Dear Dr Malone

Every resident of the City of Boston and every employee, with the exception of those employed by the Hospital Division, are sent bills if they are cared for at the Boston City Hospital. If the bill is unpaid, the case is investigated by a constable, and if, in the opinion of the latter, the patient cannot afford to pay the bill, the case is considered by the Board of Trustees.

This new regime represents a strenuous and successful effort to eliminate free beds for politicians and their friends and constituents. No doubt certain cases get by, as is bound to happen in any large institution, but the executives of the hospital are making an honest effort to remedy pre-existing conditions.

All this was brought out in the editorial "Pettyfogging Petty Politics," which appeared in the February 17 issue of the *Journal*. In the opinion of the editorial staff your letter of March 5 did not present a statement of fact, and for this reason was not published.

You question in your recent letter as to what the *Journal* has done to help the doctors in these trying times. The main function of any medical journal is the publication of papers which, it is hoped, serve to keep the practitioner informed in regard to modern medicine. The *New England Journal of Medicine* has in addition, published news items, book reviews and editorials. In the latter we have commented on the trend of government (federal, state or local) medicine and have implied that this tendency deserves serious consideration by the subdivisions of the Massachusetts Medical Society. There seems to be little more that we can do until some definite action is recommended. You can be assured that the staff of the *Journal* is of the belief that the general practitioner represents the bulwark of the medical profession, however, it seems likely that many changes will have to be made in medical practice in order that it may conform to the wants and demands of a medically intelligent, socially minded public.

Very truly yours,

ROBERT N NYE, M D

8 Fenway,
Boston.

P S If you are still of the opinion that your original letter should be published, we are willing to do so, but believe that your second letter and my two replies should be published simultaneously.

R N N

* * *

May 31, 1938

Dear Dr Nye

I thank you for the explanation why my letter was not published.

However, I think it would be to the benefit of the profession to publish my letter, and I have no objections to publishing my second letter and your two letters of reply.

CHARLES MALONE, M D

Jamaica Plain, Massachusetts

NEW RULING AT MIDDLESEX UNIVERSITY

To the Editor At a meeting of the Board of Trustees of Middlesex University on June 3, 1938, it was voted that from that date on no graduate of an osteopathic school, even though he has been admitted to medical practice in Massachusetts, will be granted advanced standing in the School of Medicine.

C RUGGLES SMITH, *President*

Middlesex University,
Waltham, Massachusetts

REPORTS OF MEETINGS

ALUMNI LECTURE, TUFTS COLLEGE MEDICAL SCHOOL

The fifth annual Alumni Lecture of the Tufts College Medical School was given at the school April 6. The presiding officer was Dean A. Warren Stearns. The speaker was Dr. George W. Holmes, of Boston, whose subject was "Pulmonary Hemorrhage."

The various conditions giving rise to bleeding from the lung are heart disease, tuberculosis, bronchiectasis, tumor, lung abscess and foreign body. At the Massachusetts General Hospital, cardiac disease is the greatest single cause of pulmonary hemorrhage, while tuberculosis is uncommon.

Every x-ray examination of the chest should be started with a fluoroscopic examination. During fluoroscopy one notices the movements of the diaphragm, the condition of the posterior mediastinum, the pulsations of the heart and great vessels, and changes in the appearance of the lung during inspiration and expiration. This preliminary examination serves to indicate what position the patient should be placed in for the x-ray and during which phase of respiration the picture should be taken. This is very important because each case is a special problem.

A series of lantern slides of x-rays was shown, starting with a normal chest during inspiration and expiration. The slides showed that during expiration one obtains a better view of the apex, that the upper portions of the lung do not deflate so much as the lower portions, and that the transverse diameter of the heart increases. A lateral plate with a barium meal in the esophagus showed that, in the living, this tube does not lie against the spine, rather, it lies close to the heart.

A diagram was shown, dividing the lung into units of bronchial supply. The importance of this feature is that once one establishes the parenchymal location of a lesion it is relatively simple to name the bronchus involved, should the lesion be secondary to bronchial disease.

Plates on a case of pneumothorax were shown. During expiration there is an increase in the size of the pleural air space and in addition there is a shift of the mediastinal structures to the side opposite the pneumothorax.

A series of atypical tuberculous problems was presented. A case of clinical lobar pneumonia with signs of right upper lobe consolidation showed many tubercle

bacilli in the sputum. In a few weeks the x ray showed no abnormal shadows. This case was interpreted as lobar pneumonia associated with ulceration of a bronchus by means of an underlying lymph node. A child was studied because of cough and wheezing. X ray showed an enlarged hilar node. A plate taken during expiration showed no deflation of the lung on that side. This was interpreted as a ball-valve type of obstruction of the bronchus by means of an adjacent tuberculous lymph node.

One case showed cough and pulmonary hemorrhage. Anteroposterior plates showed haziness of the right base. Lateral views showed collapse of the middle lobe. At a subsequent bronchoscopic examination a blood clot was found plugging the main bronchus to the right middle lobe. This was removed and prompt recovery followed.

Pulmonary hemorrhage in children should make one think of foreign body. Frequently an ordinary chest plate shows no abnormality. The foreign body, which is frequently not seen by x ray, may cause a block. Consequently, a plate taken during expiration may show lack of proper deflation of the lung.

The case of an adult who gave a good history of having aspirated a lamb bone, immediately after which he developed a continuous wheeze, was presented. Chest plates taken during inspiration and expiration were negative. A bronchoscopic examination, however, disclosed the foreign body and it was removed. Dr Holmes suggested that a film taken with a Bucky diaphragm might well have shown the bone.

Cases of congenital cystic disease of the lung are often diagnosed as tuberculosis. They have hemoptysis and are often admitted to tuberculosis sanatoriums. Several slides were shown to illustrate this mistake in diagnosis. Another condition frequently diagnosed as tuberculosis is bronchiectasis. With a good history and with lipiodol studies of the bronchi it is relatively easy to establish the correct diagnosis.

Several cases of primary lung carcinoma were discussed. One case with foul sputum was originally considered as a lung abscess, but no etiology for the abscess could be found. X ray studies showed a mass in the middle lobe. In the upper half of the mass was a cavity with a fluid level. This turned out to be a primary lung carcinoma which had become infected, giving rise to an abscess—a not uncommon situation in primary carcinoma of the lung. Another case presented a history of hemoptysis. X ray showed enlarged hilar lymph nodes. During expiration there was deficient deflation of one lower lobe and part of the upper lobe. The diagnosis was primary carcinoma of the lung, considered inoperable because of metastases to the lymph nodes. One case showed a unilateral hilar mass thought to be compatible with enlarged lymph nodes. A lateral view, however, disclosed the area of density to be within the lung itself. The diagnosis of primary lung carcinoma was finally confirmed. One case of collapsed lower lobe was shown, the collapse being on the basis of bronchial obstruction by a primary carcinoma.

Three cases, all with similar histories of upper respiratory infection and bloody sputum, were then presented. All showed x ray signs of collapse of the right middle lobe. In one of the patients, the collapse disappeared by the end of a week. He was not bronchoscoped. Biopsy of the bronchus in the other two cases revealed chronic inflammation with no evidence of tumor.

Several cases of benign tumor of the bronchus were presented. These tumors may give rise to pulmonary hemorrhage, frequently they cause bronchostenosis. Some can

be removed through the bronchoscope while others necessitate lobectomy.

Pulmonary embolism is liable to give no x ray signs unless it is complicated by pulmonary infarction. With improved x ray technic many more small postoperative infarcts are found which were previously unsuspected. Massive collapse of the lung is less common now than in the past. It frequently occurred during the Great War. It may be prevented in many instances by encouraging the patient to change his position from time to time.

Lesions other than pulmonary which may cause bleeding simulating pulmonary hemorrhage are tracheal adenomas and ruptured esophageal varices. X-rays of a typical case of each of these conditions were shown by Dr Holmes.

WILLIAM HARVEY SOCIETY

The final meeting of the William Harvey Society of the Tufts College Medical School for the current academic year was held at the Beth Israel Hospital Friday evening, May 13, Dr David D Berlin presiding. Dr Frank H. Lahey delivered the paper of the evening on the subject "Thyroid Surgery and Thyroid Disease and Some of the Newer Developments."

Dr Lahey believes that there are two types of hyperthyroid disease: (1) the so-called "activated type" and (2) the "apathetic type." The first group consists of characteristically young individuals who show great hyperactivity, marked tachycardia, enlargement of the thyroid gland, exophthalmos, and the so-called "frozen fright" facies. They usually have markedly elevated basal metabolic rates. The patient suffering from 'apathetic hyperthyroidism' is usually an elderly woman. The thyroid gland is not enlarged, there is only moderate tachycardia, and the patient appears quite calm in contrast to the extreme activity and 'frozen fright' of the activated group. The basal metabolic rate is only moderately elevated, ranging between +18 and +25 per cent in the usual case. Such cases show very striking benefit from thyroidectomy.

Hyperthyroid patients with associated cardiac decompensation but no underlying organic heart disease are classified in the 'thyrocardiac' group by Dr Lahey. He does not believe that thyroid disease in itself will produce organic heart disease. The decompensation observed in these patients is attributable to the extreme degree of cardiac activity provoked by the increased body metabolism. Operative procedures on the thyroid in such individuals usually bring about cardiac compensation which is maintained permanently after the operation. These cases are given digitalis before operation, and are treated with quinidine on the third or fourth postoperative day. Any patient with a cardiac reserve of such a degree as to enable him to tolerate subtotal thyroidectomy is practically certain to recover compensation postoperatively.

Exophthalmos is one of the most distressing complications of thyroid disease. It occurs not only in hyperthyroidism but also in myxedema. Indeed some of the most intractable instances of exophthalmos are encountered in the latter disease. In severe and progressive cases of exophthalmos Dr Lahey advises suturing the eyelids together to prevent extreme and irreversible eye changes while preparations for more permanent procedures are made. Attempts to treat exophthalmos by resection of the superior cervical sympathetic ganglia have not been successful, although this procedure does allow the lids to come closer together. The Naffziger operation in which the orbit is decompressed by removing the lateral and superior orbital walls is the most successful method of remedying severe exophthalmos. This procedure allows

expansion of the orbital tissues and muscles without protrusion of the eyeball

Dr Lahey has been impressed by the frequency of hepatic dysfunction in patients suffering from hyperthyroidism. Individuals in thyroid storm and with hyperthermia not infrequently develop jaundice. Estimation of liver function by the hippuric acid clearance test has indicated marked reduction of liver function in patients with markedly elevated basal metabolic rates. When the metabolic rate was decreased by administration of iodine the liver function improved, and after cure of hyperthyroidism by subtotal thyroidectomy the hippuric acid excretion returned to normal, indicating normal hepatic function. An accurate correlation was noted between the return of the basal metabolic rate to normal, and the return of the hippuric acid excretion to normal.

The proteogenic function of the liver is also impaired in hyperthyroidism, and there is a tendency toward lowered serum proteins in hyperthyroid individuals.

Attempts to show an increase in circulating thyroxin in hyperthyroidism have been unsuccessful, and led to determinations of the levels of blood iodine in various thyroid diseases. In hyperthyroidism there is only a small amount of iodine in the thyroid gland itself, while there is an increase in the amount of iodine in the blood. It is believed that the hyperactive thyroid gland of hyperthyroidism releases its thyroxin into the blood stream as soon as it is formed, instead of storing it in the form of colloid. This is reflected by the increase in total blood iodine. Following subtotal thyroidectomy there is a decrease of the blood iodine which returns to normal with cure. If there is recurrence of hyperthyroidism, however, there is again a rise in blood iodine. Investigations into the physiology of thyroid iodine at the Lahey Clinic have tended to clarify the above relations. Some 70 per cent of hyperthyroid patients were found to have an elevated blood iodine, the remaining 30 per cent had blood iodine levels which were normal or below normal. The levels of both groups returned to normal six months after cure by subtotal thyroidectomy. It was noted that the percentage of recurrent hyperthyroidism in patients with high blood iodine levels was very low, whereas it was 22 per cent in those individuals with normal or low levels. Those patients with low blood iodine levels suffered from a more severe form of hyperthyroidism as was indicated by the fact that 45.5 per cent of this group had to have thyroidectomy performed in several stages, while only 17 per cent of the high blood iodine group had to have stage operations. These facts are explained by the observation that patients with low blood iodine have had hyperthyroidism for a year or more and the low level is merely a reflection of the general depletion of the body's iodine. Such individuals must be treated more conservatively than those with a high blood iodine.

The blood cholesterol is an indication of the metabolic level. It is found to be decreased in hyperthyroid patients, the level varying inversely with the severity of the disease. It is elevated in myxedema, and also in chronic thyroiditis. The blood cholesterol level is actually a more sensitive indicator of thyroid activity than is the basal metabolic rate, although it cannot be used as a clinical indicator of thyroid disease because of the small range between the low normal level and the values encountered in hyperthyroidism.

Dr Lahey advised operative removal of practically all thyroid adenomas because of the fact that almost all thyroid carcinomas arise in previously existing adenomas.

In surgery of the thyroid gland it is important to

identify and make certain that the recurrent laryngeal nerves are not injured. Since adopting this principle the incidence of laryngeal palsy at the Lahey Clinic has been reduced from 1.3 per cent to 0.3 per cent. In the event that the recurrent laryngeal nerve is cut, it is important that it be resutured within three months if any degree of function is to be restored.

Of some 18,000 thyroid operations performed at the Lahey Clinic the mortality from all causes is only 0.76 per cent. Of these 115 deaths, 62 per cent were due to postoperative complications such as pulmonary embolism, heart failure, and thyroid storm. The mortality from hyperthyroid disease is much lower in Massachusetts than it is in New York and Pennsylvania, a fact which Dr Lahey attributes to the custom in Massachusetts of performing operations on the thyroid much earlier in the course of the disease.

A very interesting colored motion picture was shown which illustrated the technic of subtotal thyroidectomy.

NEW ENGLAND OTOLOGICAL AND LARYNGOLOGICAL SOCIETY

A meeting of the New England Otolological and Laryngological Society was held at the Massachusetts Eye and Ear Infirmary, Boston, on November 16, 1937, Dr Frederick T. Hill presiding. The following papers were read:

STREPTOCOCCUS MENINGITIS Dr F. B. Sargent, Providence, Rhode Island.

Four cases of acute suppurative otitis media were reported. One was complicated by meningitis and two had blood cultures that were positive for *Streptococcus hemolyticus*. All were treated with sulfanilamide and recovered.

Two of the cases which came to mastoidectomy showed that, whereas the sulfanilamide brought about prompt improvement in the patients' general condition, it did not inhibit bone destruction.

OTOLARYNGOLOGY IN THE MIDWEST: A COMPARISON OF METHODS Dr E. G. Boss, Springfield, Massachusetts

During the past several years the author spent a considerable amount of time in some of the large Midwestern clinics and thus had ample opportunity to compare the practice of otolaryngology in that region with that in New England. The following are some of his observations:

By far the greater number of tonsillectomies are performed by the general practitioners. In the James Whitcomb Riley Hospital, of Indianapolis, peritonsillar abscesses are usually opened under ether anesthesia. It appears that many Midwestern otolaryngologists perform a considerable amount of head and neck surgery which, for the most part, is pre-empted in New England by the general surgeon. In the author's opinion this state of affairs is due to the influence of Dr Barnhill. Zinc ionization for the treatment of vasomotor rhinitis has largely been supplanted by the topical application of 0.5 per cent phenol in olive oil, on the middle and inferior turbinates. Ossiculectomy is being almost totally ignored. In the Midwest, to use the author's own words, the otolaryngologist has won the argument as to whether the Mosher-Tott operation belongs to him or to the ophthalmologist. Several instruments which were invented by Midwestern otolaryngologists were shown

TWO CASES OF ANEMIA FOLLOWING THE ADMINISTRATION OF SULFANILAMIDE. Dr W E Kershner, Bath, Maine.

Two cases of hemolytic streptococcal mastoiditis treated with sulfanilamide were reported. They were of like severity and occurred in otherwise healthy individuals. During the administration of the drug both cases developed anemia, the red-blood-cell count dropping to 3,300,000 and 2,900,000 respectively. In both patients the blood picture returned to normal after the drug had been discontinued.

LUNG ABSCESSSES AT THE BOSTON CITY HOSPITAL. Dr L. M. Freedman, Boston

The author made an exhaustive study of all lung-abscess cases observed at the Boston City Hospital during the ten year period from 1926 to 1936. There were 276 proved cases. Two hundred of these were of medical origin, the remaining 76 occurred as postoperative complications. Of these latter only 16 followed tonsillectomy. In comparing the numbers of the various operations it was found that the ratio of lung-abscess cases to the total number of tonsillectomies was 1/1654, whereas in dental cases it was 1/320, and after gastric operations 1/54. All tonsillectomies were performed in the upright position. Inasmuch as only 1 lung abscess occurred in 1654 tonsillectomies, the author feels that position is of no importance as an etiologic factor. The preoperative condition of the patient is of great importance. The author is convinced that the most potent cause of pulmonary complications is the infection present in the upper or lower respiratory tract before operation. A rather dramatic case was cited: a patient was not passed for tonsillectomy on account of a lower respiratory infection, he developed a lung-abscess which would have been laid at the door of the tonsillectomy had it been performed.

This paper has since appeared in full in the *New England Journal of Medicine* (218 663-668, 1938)

INNER EAR DEAFNESS OF UNUSUAL ETIOLOGY. Dr P B MacCreedy, New Haven, Connecticut.

A case of inner-ear deafness which occurred following the injection of a prophylactic dose of tetanus antitoxin was reported. The case was unique inasmuch as the two other cases which have been reported in the literature followed massive doses for the treatment of tetanus.

USE OF TUNING FORKS. Dr W Mueller, Boston

A brief demonstration of the various types of tuning forks was given, with special reference to such forks as are usually found in the otologist's office. Inasmuch as the audiometer is not as yet the ideal instrument for audiometry, a plea was made for the proper appreciation and use of the tuning fork. The manner of striking and holding the various forks is important. Forks used for the Rinne test should be standardized on a goodly number of subjects with supposedly normal hearing. If the standard for bone and air conduction of such a fork is kept in mind, much can be learned from the Rinne test as regards the type and severity of the patient's deafness, and, incidentally, the Schwabach test is rendered unnecessary.

ATROPHIC RHINITIS. THE CONSTITUTIONAL FACTOR AND THE TREATMENT WITH ESTROGENIC HORMONES. Drs H. Mortimer, R. P. Wright and J B Collip, Montreal, Canada.

This paper appeared in full in the *Canadian Medical Association Journal* (37 445-456, 1937). The following is the authors' summary

1 Study of the cranial skiagrams of 68 cases of atrophic rhinitis and ozaena gave evidence, in a large majority, of a dyspituitary state during or subsequent to the growth period.

2 It is suggested that the disease occurs as a genetically transmitted, more or less localized, focus in a special familial constitution, produced by the mating of dyspituitary individuals, in whom anterior lobe function is unstable in secretory activity, nature or time of activity. It is on this basis that the nasal osseous changes are to be understood.

3 Speculation as to the mode by which a dyspituitary constitution might influence the morphologically specialized conchal mucosa led to the investigation of the nasogenital relationship in the monkey, and recognition of the fact that administration of oestrogenic substance produces a specific response in the conchal mucosa, closely akin to that resulting in other 'sex skin' areas, as already reported.

4 That such specific changes are of an order opposed to the pathological changes occurring in atrophic rhinitis justified the exhibition of dihydroxy-oestrin locally to the nose in this disease.

5 Thirty-one female and 7 male patients were available and treated, with results justifying the conclusion that in oestrogenic hormone insufflation there is to be found a therapy for ozaena and atrophic rhinitis considerably more effective than any other till now available.

6 Seven patients were found suffering from both atrophic rhinitis and progressive deafness, an eighth case showed both otosclerosis and hypertrophic rhinitis.

NOTICES

UNITED STATES CIVIL SERVICE EXAMINATIONS

Medical Officer, \$3,800 a Year
Associate Medical Officer, \$3,200 a Year

Applications must be on file with the United States Civil Service Commission at Washington, D. C., not later than July 18.

Applicants, in order to become eligible, must qualify in at least one of the following optional branches, and must state in their applications the branch, or branches, desired: (1) cardiology, (2) dermatology, (3) eye, ear, nose and throat (singly or combined), (4) industrial medicine, gas analysis or toxic dust, general, (5) internal medicine and diagnosis, (6) medical pharmacology, (7) pathology and bacteriology, (8) public health general, venereal disease, (9) roentgenology, (10) surgery general, orthopedics.

Medical-officer applicants must have had 1 year of internship, general rotating or in a special branch, and 3 years of experience in the practice of medicine.

Associate medical-officer applicants must have had 1 year of internship in the optional branch claimed, privately or in some recognized hospital.

The necessary forms may be obtained from the Secretary, Board of United States Civil Service Examiners, at any first-class post office, or from the United States Civil Service Commission, Washington, D. C.

BOOK REVIEWS

Annual Reprint of the Reports on Pharmacy and Chemistry of the American Medical Association for 1937 201 pp. Chicago American Medical Association, 1938. \$1.00

This book is a great deal more than a mere record of the negative actions of the Council on Pharmacy and Chemistry of the American Medical Association. It gives

in full the reasons for the council's rejection of various preparations, but it also records results of investigations of new medicinal agents not yet out of the experimental stage, and frequently contains reports on general questions concerned with the advance of rational drug therapy. All three categories of reports are represented in the present volume.

This issue of the reports is remarkable for the series of valuable status and preliminary reports published by the council in the past year. These include the reports on Avertin with Amylene Hydrate (now accepted), Benzidine Sulfate (the active constituent of the notorious "pep" pills but a promising drug when its limitations are recognized), catgut sutures (a survey of the sterility of the market supply), Evipal Soluble (a comprehensive review of the evidence for the usefulness and limitations of the drug), histidine hydrochloride (a study of the usefulness of the drug in peptic ulcer, to be considered in connection with the report rejecting Larostidin, a proprietary brand for unwarranted and exaggerated claims), mandelic acid (an authoritative statement of the limitations of this drug which the council has now accepted) and Vinethene (a careful study of the evidence for the drug, which the council has accepted for one year as an anesthetic to be used in short procedures).

Other notable reports of outright rejection of products are those on Causalin (an unsafe and dangerous preparation proposed for use in arthritis), Glutamic Acid Hydrochloride—Calco (proposed as a conveyor of hydrochloric acid, with unsubstantiated claims of clinical effectiveness) and Larodon 'Roche' (proposed as a substitute for other well-established analgesic and antipyretic drugs and marketed with exaggerated and unwarranted claims).

Two reports on sulfanilamide appear,—a nomenclature and status report,—together with reprints of editorials that appeared in the *Journal of the American Medical Association* and that gave warnings which, if obeyed, would have avoided the series of deaths which resulted from the marketing of the ill-fated Elixir of Sulfanilamide—Massengill.

At the end of this volume appears a eulogy of George Henry Simmons, whose death deprived the Council on Pharmacy and Chemistry of its founder and American medicine of a worthy and faithful servant.

Wheeler and Jack's Handbook of Medicine Revised by John Henderson. Tenth edition. 703 pp. Baltimore William Wood & Co., 1937. \$4.00

The editor, John Henderson, of Glasgow, emphasizes that this work is only a handbook and not a textbook of medicine. It covers the field fairly comprehensively, is simple and concise in style, and brings out highlights. This accounts, very likely, for its popularity, being a tenth edition and the sixteenth printing. However, on glimpsing through its pages, one misses some of the advances in medicine that have been made during the past few years.

The Hospital Head Nurse Her Functions and her Preparation Mary Marvin Wayland. Edited by Isabel M. Stewart. 388 pp. New York The Macmillan Company, 1938. \$3.50

The writer of this book is a registered nurse who has occupied several important teaching positions, has been honored with an A.M. degree, and is the wife of a physician. She sets forth the duties and responsibilities of the head nurse of a well-equipped hospital.

Beginning with a brief history of the evolution of the art and science of the nursing profession she proceeds to

define the functions of a modern hospital and the position of the nursing profession in the administration of such institutions. It is made clear that the head nurse should be a well-educated and trained official with accurate knowledge of the duties of all departments of the hospital and with an ambition to bring the nursing service into sympathetic and co-ordinate relation with the medical profession and all other agencies designed to promote success in dealing with the problems of illness.

The training of nurses according to the ideals of the author presupposes that only women of good natural ability and preprofessional education will be able to meet the exacting curriculum of the ideal training school for nurses. When graduated, such nurses ought to be eligible for important positions in the nursing field.

All allied interests designed to qualify graduates for hospital appointments are also set forth.

Doctors, nurses and hospital administrators will find this book interesting and instructive. It is well written and the bibliography is voluminous.

Modern Dietary Treatment Margery Abrahams and Elsie M. Widdowson 328 pp. Baltimore: William Wood & Company, 1937. \$3.25

The problems pertaining to nutrition were, until comparatively recently, very largely considered from an empirical standpoint but, with scientific studies of calories, vitamins and basal metabolism, the needs of the human body are now being dealt with more satisfactorily than formerly, because the biochemist and pathologist have taught the underlying facts relating to malnutrition and the effects of many disease processes.

Among the many books now available relating to nutrition, this one, by the dietitian to Bartholomew's Hospital and the biochemist to Kings College Hospital, sets forth the important known facts clearly and concisely, with a wide variety of food lists which are applicable to the conditions which require specific dietary treatments.

This small volume is well written in orderly fashion and will be useful for physicians and nurses and may be put into the hands of intelligent laymen with safety after the doctor has told the patient the nature of his trouble.

A Biological Approach to the Problem of Abnormal Behavior Milton Harrington 459 pp. Lancaster: The Science Press, 1938

In a previous book (*Wish Hunting in the Unconscious*) Dr. Harrington critically studied psychoanalysis but did not formulate his own approach to the problem of abnormal behavior. In this book he goes on to develop the biologic mechanistic basis of abnormal human behavior. On the whole it may be stated that Dr. Harrington is better as a critic than as an original thinker, although his book is valuable and provocative.

First, as to the defects of the book. The book suffers from the underlying philosophy of the writer, which is to the effect that unconsciousness is an epiphenomenon and has no real relation to the activity and conduct of the human being, thus accepting the position of Thomas Henry Huxley. This philosophic approach is merely one of despair. It is difficult to handle consciousness. It cannot be measured easily. It is something measurable only in terms of itself. It is the sum total of sensory and kinesthetic awareness, — whatever that may mean, — and yet it does not fit into the ordinary schemes of causation and is not easily measured. But it cannot be thrown out because of our lack of understanding or our logical difficulties. By discarding it, one finally is reduced to the

absurdity, which has long since been pointed out, of postulating an unconscious Shakespeare writing his great plays for an unconscious audience and performed by an unconscious set of acts, and thus without impairing the realities of a glorious situation. Moreover, after Dr. Harrington has laboriously kicked out consciousness via the front door, he finally has to readmit it in his discussion, which is mainly as if he accepted consciousness as the real value of life. In his discussion of unconscious thinking, he very directly states that consciousness is the basis of mind and that there can be no such term as unconscious mind, 'which seems to give away his central position. Thus, consciousness slips in again by the rear door.

The reviewer also believes that Dr. Harrington is too much swayed by what he calls the law of parsimony in science. As a matter of fact, there is no such law. It is merely a convenience to establish as few causes as possible. In actuality there is no one cause to anything. There are a flood of variables which have to be considered, and the more variables included, the greater the structure of results. What he uses as a guiding principle has been discarded in the practical workings of science long ago.

So much for criticism. On the whole, the book emphasizes that pleasure and pain, and satisfaction and dissatisfaction, which in turn are created by the constitution of the individual, by the stimuli which flow in on him, and by the standards which have been set up in him by the social milieu in which he finds himself willy nilly, are the leading factors in the production and understanding of abnormal behavior. The emphasis on the biochemical mechanistic background is necessary at the present time. The adherence to things which are provable rather than those which are built up by metaphor, symbol and adroitness is especially important at this period of psychiatry and psychology.

Dr. Harrington builds up a dynamicism of conduct. The steps are discernible without recourse to too dubious inference. One valuable phase of his book lies in the consideration he has given to the absurdity of social requirement, so that an individual may be plunged into difficulties, not so much through his own defects as through the abnormal and impossible demands of society. The author emphasizes the fact that unsatisfactory relations breed a chain of events which finally leads to crime and neuroses, as well as to the minor deviations from satisfactory and satisfying human conduct.

The book suffers from the defect that the author is too much occupied with the desire to contradict and displace the Freudian doctrines. Its value lies in the fact that the onesidedness of psychoanalysis and the other allied approaches to human conduct need to be corrected — certainly so far as present-day psychiatry goes — by the vigorous demonstration that man and all his products are biologic, that biochemistry, electric currents and pharmacological experimentation — to cite only a few of the scientific approaches — can explain and also modify human conduct.

Digestive Tract Pain: Diagnosis and treatment experimental observations Chester M. Jones 152 pp. New York: The Macmillan Company, 1938. \$2.50

This book is an interesting and valuable contribution to the study of digestive tract pain, particularly the localization of pain and its character at different levels in the digestive tube. Experimental study is based on a method used by other investigators, namely the introduction of a distensible balloon into various levels of the digestive tube and the production of symptoms through distention

of these local segments by introduction of air into the balloon. The record of experimental observations is followed by protocols demonstrating the clinical application of the facts observed to the diagnosis of pain at various levels of the digestive tube. A chapter on gastrointestinal pain in functional disease emphasizes the importance of recognizing this type of disorder in differential diagnosis, and its treatment by medical routine and psychotherapy. The final chapter summarizes the sources of digestive tract pain and contains a discussion of therapeutic measures, emphasizing particularly a point in which internists welcome emphasis, namely the value of rest and relaxation in all digestive-tract diseases except the obviously surgical ones.

Of practical interest to the clinician is the corroboration by further experimental data of the following facts, already well established clinically: (1) A disturbance in the neuromuscular mechanism of the digestive tract, producing pain, can be localized when produced both experimentally and by disease, and the localization and character of both types (experimental and pathologic) correspond very closely. (2) The common symptom of heartburn is caused by abnormal neuromuscular activity at the cardiac end of the esophagus, and is independent of the chemical character of the gastric secretion. Internists have recognized this fact clinically because the symptom occurs in patients with normal and with both extremes of abnormal gastric acidity, and because it is so often associated with the habit of belching and with other abnormal gastric neuromuscular activity, such as pylorospasm. (3) Constitutional or neighborhood disease must be recognized as a cause of gastrointestinal pain and digestive symptoms—a fact already well established in the minds of experienced internists. And as a corollary, the importance of backache is discussed as a symptom of gastrointestinal disease such as ulcer or spasm due to gall-bladder disease or to functional disturbances.

The author has successfully presented a concise and precise study of the mechanism of referred gastrointestinal pain, to which he has attached an interesting correlation of diagnostic and therapeutic data from his clinical experience. In its entirety, this book gives further evidence of the fact that in the study of digestive diseases, a careful history, properly evaluated, is an essential part of the diagnostic data.

New and Nonofficial Remedies—1938 Containing descriptions of the articles which stand accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1 1938. 589 pp. Chicago: American Medical Association, 1938. \$1.50.

In this book the Council on Pharmacy and Chemistry lists and describes the medicinal preparations that it has found acceptable for general use by the medical profession. A glance at the list of the council members and the long list of consultants appearing in the first part of the book gives ample warrant for the authority of the council's selections.

New substances described in this volume are sulfanilamide and protamine zinc insulin, with the accepted brands. The proved value of these new additions to the physician's armamentarium bids fair to make the past year a milestone in therapeutic progress. The council is to be congratulated on the promptness with which it evaluated these drugs and established standards for their adequate control. From the first the council warned against using sulfanilamide in untried combinations. The sad tragedy of the deaths from the rashly introduced

Elixir of Sulfanilamide—Massengill, starkly emphasizes the value of such a body as the council to the medical profession and the pharmaceutical manufacturers, as well as to the public. Of course this potential value cannot become effective so long as those concerned refuse to follow the recommendations of the council regarding the use of new remedies.

Other noteworthy new drugs which appear in *New and Nonofficial Remedies—1938* are Avertin with Amylene Hydrate, Vinethene and Pontocaine Hydrochloride, basal, general and local anesthetics respectively, Novatropine and Syntropan, synthetic mydriatics.

Physicians who wish to know why a given proprietary is not described in *New and Nonofficial Remedies* will find the "Bibliographical Index to Proprietary and Unofficial Articles Not Included in N.N.R." of much value. In this section (in the back of the book) are given references to published articles dealing with preparations that have not been accepted. These include references to the reports of the council, to reports of the American Medical Association Chemical Laboratory and to articles that have appeared in the *Journal of the American Medical Association*.

Physiological and Clinical Chemistry, William A. Pearson and Joseph S. Hepburn. Second edition. 467 pp. Philadelphia: Lea & Febiger, 1938. \$5.50.

The second edition of *Physiological and Clinical Chemistry* is replete with information and contains much out-of-the-way material. However, certain difficulties will be encountered in using the book as a textbook of clinical chemistry because the material presented is of a mixed quality, being either too sketchy or too involved. For example, the student may be misled in the section on vitamins and hormones by the simplicity of certain sweeping statements and by intricate descriptions of rather unimportant isolated facts. The book lacks bibliography so that one is lost as to where to go in a further search for material to expand the information. The text is characterized by certain technical descriptions which appear to be gleaned from other sources and by somewhat hazy explanations of underlying principles. One can overlook such errors of spelling as those of names like Tisdall. Possibly future editions will rectify such mistakes. The section on blood analysis is somewhat impractical and labored, without being up to date. The book is recommended only to those who may wish to find some out-of-the-way material.

Men Past Forty, A. F. Niemoeller. 154 pp. New York: Harvest House, 1938. \$2.00.

This book aims to give the layman a reasonably thorough understanding of the nature of sexual impotence and its treatment. The author seems not to be a physician but has a good knowledge of physiology as related to the subject in question. His lack of medical training probably accounts for a few rather startling statements such as the assertion that coitus reservatus, if practiced over long periods, leads to "the inflammation and stricture of the urethra, the inflammation and stricture of the prostate gland etc."

The acceptance of certain preparations such as the extract of fresh testicle, also shows an absence of scientific judgment. The author's discussion of rejuvenation by means of Voronoff's and Steinach's operations is very superficial; it might well be misleading. The discussion of the psychic phases of impotence, on the other hand, is better than one usually finds in books on this subject.

Men Past Forty will probably prove to be both interesting and helpful to the not too-critical lay reader. It is essentially sound, and if the reader is not driven off by the rather affected style in which it is written, he should be well repaid for the time spent.

Pavlov and His School The theory of conditioned reflexes
Y P Frolov 291 pp New York Oxford University Press, 1937 \$4.00

This is the most interesting and easily readable life of Pavlov that has been published. It gives, moreover, his final opinions in regard to the conditioned reflex, with which his name will always be associated in the history of physiology. There is considerable material, moreover, about Pavlov's immediate predecessors, facts which are not easily available in English. As a well written life of the author, and especially as a considered evaluation of his work, this book should receive the highest recommendation. The translation is finely done and there are numerous illustrations.

Illness Its story and some common symptoms, a guide for the layman S Henning Belfrage. 173 pp New York Oxford University Press, 1938 \$1.50

This small book is a guide for the layman with respect to illness and presents, in nontechnical language, arguments for the early recognition of departure from normal conditions of the human body. The common symptoms associated with functional disorders and organic diseases are explained, with advice to consult the doctor early and not depend on home remedies. There is no discussion of controversial theories or matters beyond the grasp of people of ordinary intelligence.

It is a book which the doctor may properly advise his patients to read because it would stimulate more interest in the prevention and cure of disease.

Les Explorations Fonctionnelles Noël Fiessinger 430 pp Paris Masson & Cie, 1937 70 Fr fr

This book brings together in a critical and orderly manner a large variety of functional tests applicable both in the clinic and in the laboratory. The author is careful to announce in the introduction that the tremendous number of laboratory procedures available, while aiming to increase the scope of our understanding of various disorders and to assist in guiding the application of many therapeutic procedures, do not totally supplant careful clinical observations. The book contains chapters dealing with procedures designed to evaluate the various functions of the stomach, the pancreas (both exocrine and endocrine), the intestines, the liver and bile passages, the kidneys, the spleen and reticuloendothelial system, the hematopoietic organs, the endocrine glands, the respiratory apparatus, and the cardiovascular and nervous systems. The author has previously published eight more or less extensive monographs, of which four have dealt with the pathologic physiology of the liver. It is not surprising, therefore, that almost a third of the present volume is devoted to the liver and biliary tract. Many of the tests described will be quite unfamiliar to American readers, but most of the ones better known to us are also included. The sections dealing with the cardiovascular, the respiratory and the nervous systems receive rather scant treatment, and those concerning hematology will seem quite old fashioned to American readers.

The table of contents is very carefully and logically arranged but the only index available is one of authors. Unfortunately, although some 600 authors are listed and

some are referred to as many as fifteen or twenty times in the text, there is no bibliography included. Like French works, this one refers predominantly to French writers although the work of a large number of American workers is mentioned.

Synopsis of Genitourinary Diseases Austin I. Dow Second edition 294 pp St. Louis The C. V. Mosby Company, 1937 \$3.00

The reviewer was so pleased with this little book he cannot praise it too highly. Its conciseness and brevity are refreshing in comparison to the monumental thousand page tomes which are so common, yet it covers the fully and well merits its title. The fundamental genitourinary diseases and the principles of their diagnosis and treatment are presented very clearly and completely with numerous illustrations and definite practical suggestions.

There is nothing in the book describing the technique of cystoscopy or of any operations. The reviewer might have realized that there is no room for them in a synopsis, and believes that a companion book by the author on the technique of cystoscopy and of operation on the genitourinary tract would be welcome. Although the reviewer did not agree completely with the author on some minor aspects, he highly recommends this clear synopsis to the medical student, the practitioner of medicine and even to the trained urologist.

Surgical Diseases of the Mouth and Jaws Earl C. Padgett 807 pp Philadelphia and London W. B. Saunders Company, 1938 \$10.00

The author has designed a comprehensive volume of the surgical conditions of the mouth and jaws. The book brings up to date the extensive material on this subject. The problems of maxillofacial surgery are such that they create a common ground for the dental and medical professions, and this ground is well covered by Dr. Padgett for both the student and the expert. Classifications are well carried out with the avoidance of overlapping in coverage of various topics. The author has complied with the requirements of the Curriculum Committee of the American Association of Dental Schools.

Considered in detail we discover a pertinent bibliography at the end of each chapter. In the first few chapters the traumatic injuries of the face and jaw are described. Soft-tissue injuries and facial bone fractures are discussed with illustrations of the specialized splints necessary in the management of these cases. In the second group of chapters is found a discussion of the inflammatory diseases of the face and jaws. The congenital deformities, including cleft palate and harelip, are considered in the third group of chapters. Benign and malignant tumors are outlined next, and in the final portion of the book the surgical techniques necessary to carry out special operations are presented along with a discussion of essential prosthetic restorations.

It is unavoidable in this kind of book to afford as complete coverage of some topics as others, since the author's special interests must be reflected to some extent in the output. The reviewer found special values in the chapters on harelip and cleft palate and in the section on malignant tumors.

In summary, this is a valuable textbook for the student and a useful reference book for the surgeon. The illustrations, of which there are three hundred and thirty-four, are especially well chosen and helpful.
